Science Education: Basic Science Research

P1/B1

Extracurricular Biology Research in a High School Setting.

A. Krishnan, C. Chopra, S. Flynn, R. Gupta, G. Pereira, R. Sabherwal, S. Tyson, M. Fields; Sidwell Friends School, Washington, DC.

Students at Sidwell Friends School in Washington, D.C. have the opportunity to conduct original research both inside and outside of the classroom. If a student wants to do research after completing one year of Biology they can join the BRAIN (Biological Research and Investigations in Neuroscience) Club or partner with scientists from other research institutions. Extracurricular research enables students to employ research techniques they have gained through science classes in lab-like settings. This year, students chose to conduct experiments *Danio rerio*, or zebrafish. Their projects include: (i) Vision is vital to many animals and some have mechanisms to repair damaged retinas. We tested how Gamma-Amino Butyric Acid (GABA), a neurotransmitter known for calming nervous activity, would affect that ability. Blinded zebrafish were exposed to various concentrations of GABA and their recovery was monitored. We found high levels of GABA blocked the regeneration of damaged retinas, often stopping regeneration triggered by secreted growth factors. (ii) Fluoxetine (Prozac) is a selective serotonin reuptake inhibitor (SSRI) and a commonly-prescribed antidepressants. Though acute fluoxetine is rarely, if ever, administered in humans, acute treatment of zebrafish mirrors the “lag period” of SSRI effectiveness in humans. As such, this experiment aims to study the differing behavioral effects of chronic and acute fluoxetine on novel tank diving behavior in *Danio rerio*. (iii) We are testing the effects of Ethanol on adult Zebrafish motor skills. One group will be exposed to a 1% Ethanol solution, one group will be exposed to a 2% solution, one group will be exposed to a 3% solution, and one group will not be exposed. In conclusion, we have found that the group exposed to the 3% solution exhibited the largest decrease in motor skills. (vi) We will quantify the effects of sugar and artificial sweetener on the development of zebrafish embryos. Expected results include deformities and defects in the head area and death (aspartame), as well as obesity and accelerated heart rate (sugar). We will conduct this experiment by creating varying concentrations of sugar and aspartame. We will quantify our results using Image J to measure spinal curvature and any defects we see, and recording embryo death. (v) the biodegradability, biocompatibility, and minimal immunogenicity makes collagen a valuable biomaterial. For each application of collagen, the properties of the collagen need to be optimized. In this study, the length of the de-hydrothermal treatment and the materials morphology were varied to characterize the effect of the material processing and morphology on the mechanical properties and in vitro collagenase resistance of the collagen matrices.

P2/B2

Introductory Biology Research in a High School Setting.

A. Krishnan, V. Chuadhry, A. Donnelly, R. Gupta, **A. Krishnan**, M. McGraw, A. Oswald, A. Sabherwal, A. Selassie, E. Yu, M. Fields; Sidwell Friends School, Washington, DC.

Students at Sidwell Friends School in Washington, D.C. have the opportunity to conduct original research both inside and outside of the classroom. If a student wants to do research after completing one year of Biology they can join the BRAIN (Biological Research and Investigations in Neuroscience) Club or partner with scientists from other research institutions. Extracurricular research enables

students to employ research techniques they have gained through science classes in lab-like settings. This year, students chose to conduct experiments *Danio rerio*, or zebrafish. Their projects include: (i) in this experiment, we observed the effect of nitrites and nitrates on zebrafish embryos. We tested a total of 6 groups of 25 zebrafish embryos each: one low concentration of 100 mg/L and one high concentration of 300 mg/L for both nitrites and nitrates as well as two control groups. We analyzed the teratogenous effects of nitrogen-based runoff and fertilizers and how these factors contribute to the development of pericardial edemas and axial malformations. (ii) in our experiment, we are observing the effects of elevated glucose exposure on the development of zebrafish embryos. This is similar to gestational diabetes, where the fetus experiences various harmful effects because of the early exposure to elevated glucose. Zebrafish embryos will be placed in regular embryo water, 0.5% glucose solution, 0.25% solution and 0.1% solution for 4 days. We are testing for mortality rate, yolk-sack size and weight. (iii) One of the most pressing issues today is pollution, specifically of our oceans. The sun causes plastics, such as polyethylene terephthalate (PET), to break down, releasing toxic chemicals into the water. This causes zebrafish embryos to hatch later, have increased mortality, and demonstrate abnormal characteristics. Our experiment mimics the effect of plastic contamination on aquatic life and highlights the damage of human pollution. (iv) It is commonly perceived that e-cigarette fluid is a safer alternative to traditional cigarettes. We were interested in comparing the effects of both substances on developing zebrafish. We exposed the embryos to different concentrations of nicotine and e-cigarette fluid. We found that the group exposed to e-cigarette fluid developed more axial malformations which resulted in a decreased capacity for fine motor skills as well as a higher mortality rate. (v) Roundup is used by millions of people every day as the world's most popular herbicide. Recently there has been controversy surrounding the effects of the herbicide. Improper application can lead to cancer and other diseases. This experiment tests whether RoundUp can cause motor system failures.

P3/B3

Computational Comparative Genome an alysis of Salmonella Enterica Subsp Enterica Serovar Reading.

S. Kang[1], D. Kim[1], S. Baek[1], S. Kim[2], S. Chung[2]; [1]Johns Hopkins University, Baltimore, MD, [2]FTI, Rockville, MD.

Salmonella enterica subsp. *enterica* serovar Reading is a multidrug-resistant food-borne pathogen of which infections in human have accounted for serious illness including mortality. Genome sequences of seven hundred and ninety-nine *Salmonella* Reading isolated from 27 resources in 11 countries at 21 year-points were downloaded from National Center for Biotechnology Information database. Single nucleotide polymorphisms profile was constructed using Parsnp and the evolutionary history was inferred using the Maximum Parsimony method with 100 bootstraps on MegaX. Antimicrobial resistance genes in each genome were identified using AMRFinder with NCBI's Bacterial antimicrobial Resistance Reference Gene Database. Prophage and virulence factors were identified using blast with prophage and virus DB from PHAST and *Salmonella* VF database from Virulence Factors of Pathogenic Bacteria, respectively. *Salmonella* Reading were clustered to 7 clades and phylogenomic differences were likely correlated to countries and sources. Antimicrobial resistance genes abundance differed between countries while virulence factors and prophage were similar in all genomes.

P4/B4

Enhancement of Power Generation in Microbial Fuel Cell through Supplementation of Platycodon Grandiflorus Roots.

C. Han[1], S. Chung[2]; [1]Carnegie Mellon University, Pittsburgh, PA, [2]FTI, Rockville, MD.

The current study reports the evidence of enhancement in power generation from cellulosic biomass in microbial fuel cell (MFC) systems by supplementing Chinese bellflower (*Platycodon grandifloras*) roots powder. Mediator-less two chamber H-type MFCs were prepared using rumen fluid as anode inocula to convert finely ground pine tree (Avicel) at 2% (w/v) to electricity. Dried bellflower roots were ground to pass 1mm sieve and added to the anode of MFC at 0.1% w/v dosage for treatment. MFC power and current across an external resistor were measured daily for 10d. At the end of incubation on d10, collected gases were measured for total gas volume and analyzed for gas composition on gas chromatography. Supplementation of bellflower roots powder to MFC anode chamber increased power generation and CO_2 production. Over the 10d experimental period, power density normalized to anode surface area were between 17.0 and 37.7 with average of 32.5 mW/m^2 in bellflower MFCs, and between 16.8 and 19.8 with average of 18.2 mW/m^2 in control group. These observations imply that Chinese bellflower root components would alter microbial fermentation of cellulose compounds favorable to produce bioenergy efficiently in MFC.

P5/B5

Transportation of Human Primary Hepatocytes for Transplantation.

S. Chang[1], D. Ho[2], S. Chung[3]; [1]Johns Hopkins University, Baltimore, MD, [2]Hememics, Rockville, MD, [3]FTI, Rockville, MD.

Cells preserved in dry ice, liquid nitrogen or live cells in complete medium are current methods used for cell shipments. These methods require special handling and there is limited survival time for cells during the transportation process. Here we report a novel shipping procedure that is inexpensive, environmentally superior and protects cell viability and integrity at ambient temperature. We prepared mammalian cells using Cell Transportation Matrix (CTM™) with protocol provided by the manufacture and kept the cells at room temperature (RT) for 7 days. Cells maintained in CTM™ at room temperature for 7 days have greater than 80% viability, and retained full biological functions. All together, unlike dry ice and liquid media, CTM™ shipping is a novel way to transfer and ship cells with positive economic, practical and environmental implications.

P6/B6

A Semester-long Undergraduate Molecular and Cellular Biology Laboratory Project.

K. Chambers; Concord University, Athens, WV.

A laboratory curriculum was developed to introduce undergraduate molecular and cell biology students to multiple techniques commonly used in the field in the context of an extended laboratory project. Over the course of the semester, the students clone the human α-tubulin (TUBA1B) cDNA into a green fluorescent protein mammalian expression vector (pEGFP) and express it in mammalian cells. The localization of the fusion protein is then visualized using fluorescence microscopy. Using this fluorescently-labelled recombinant protein, students then observe the effects of nocodazole on microtubule networks in cells. Finally, students complete an exercise that exposes them to the field of

bioinformatics. As this project is part of an undergraduate course, it is designed for all skill levels and is accessible for numerous students. It allows students at a small liberal arts institution to acquire skills in many molecular and cell biology experimental techniques and gain a research-like experience. The project provides students with a conceptual understanding of various techniques and how they can be used in conjunction to answer scientific questions. Additionally, students develop analytical and critical-thinking skills. Each week students interpret data and assess the reliability of their results. Unlike traditional "cookbook" labs, students are asked to recall and relate data from week to week over the course of the entire semester. At the end of the semester, students communicate their results in a conference-like poster presentation and discipline-appropriate scientific paper.

P7/B7

Incorporation of Crispr/cas9 into a Semester-long Investigative Lab on the Cell Biology Of*C. Elegans*.
G. De La Torre Pinedo, S. K. Olson; Pomona College, Claremont, CA.

Course-based undergraduate research experiences (CUREs) provide authentic research opportunities in a classroom setting, allowing greater numbers of students to be exposed to the scientific process and to truly take ownership of their projects, which in turn encourages more students to pursue careers in science. For the past few years, we have incorporated CRISPR/Cas9 technology into the lab component of an Advanced Cell Biology class to introduce undergraduate students to this cutting-edge technology. Students design CRISPR-based independent projects that explore various facets of C. *elegans* eggshell assembly, which is the focus of our research lab. Thus, students generate novel data that furthers our lab's research agenda. Several different CRISPR approaches are commonly used in the C. elegans community, so we explored 3 different methods to find the one that best balances successful edits, time, cost, and pedagogical goals. First, students in the Fall 2017 class used the streamlined and modular SapTrap method (Schwarz & Jorgensen) to modify their chosen protein with fluorescent tags, affinity tags, and degrons. With this method, 6/8 groups successfully cloned their constructs, 4/8 saw evidence of genome edits, and 1/8 were able to perform their proposed experiments. In Summer 2019, a group of high school students spent 4 weeks learning about CRISPR and working on a plasmid-based method that incorporates PCR, cloning, and selectable markers (Dickinson & Goldstein). The students successfully generated the DNA building blocks, but the session ended as they were ready to assemble their vector. In Fall 2019, Advanced Cell undergraduate students used a co-CRISPR approach (Paix & Seydoux, Arribere & Fire), where they had the option of fluorescently-tagging their protein or generating a mutant. Students designed the guide RNA and homology-directed repair oligos, and screened for edits in injected worms. They spent the remainder of the semester studying their edited worms to explore localization patterns, phenotypic changes, and/or protein interactors, with the overall goal of understanding the role of their protein in C. *elegans* eggshell formation. Six of the 8 groups had successful genome edits within 4 weeks and were able to conduct their independent studies. The most recent approach seems the most promising for efficiency, but is limiting in the number of edits that can be made with one injection, and is significantly more costly than the plasmid-based approaches. Ongoing efforts aim to reduce the amount of work outside of class hours and to allow for more flexibility in edit designs.

P8/B8

Characterization of Novel Immortalized Mouse Renal Proximal Tubular Epithelial Cells.

M. Schmidt[1], K. Otterpohl[2], B. Busselman[2], I. Chandrasekar[2]; [1]NSF-REU summer student from Drake University, Sanford Research, Sioux Falls, SD, [2]Sanford Research, Sioux Falls, SD.

Nonmuscle myosin 2 (NM2) play critical roles in cell adhesion, migration, and cell division. Previously, we also demonstrated NM2's role in clathrin-mediated endocytosis (Chandrasekar et al; 2014). In order to further study the role of NM2 in cellular transport pathways, our lab uses mouse kidney and renal epithelial cells as a model system. My research directly dealt with mouse proximal convoluted tubule (PCT) epithelial cells generated from conditional knockout mouse model of the *Myh10* (NM2B) gene. These mice were crossed with a temperature sensitive, immorto SV-40 antigen +/Tg mouse in order to immortalize the cells. The goal of my summer project was to characterize the PCT *Myh10* cKO cell line and confirm its applicability as an in *vitro* research tool. The PCT *Myh10* cKO cells were cultured on trans-well polyester membranes for 2 days at the permissive 33C, to enable cell proliferation and then moved to 37C on an orbital shaker to mimic fluid shear stress experienced by renal cells and to facilitate maturation and polarization for up to 6-8 days. Some membranes were treated with doxycycline for 48 hours to initiate the *Myh10 gene* knockout. The cells were fixed and stained using immunofluorescence methods or made into lysates for western blots in order to identify the localization and expression patterns of proteins specific to PCT cells. Many treatments including a fibronectin coating of the membrane, 5%, 20%, 60% collagen coat, and lysophosphatidic acid (LPA) were used to promote polarization of the PCT cells.Immunofluorescence confocal microscopy revealed that large pockets of cells in culture were polarized and grew to 5-8 µm in height in the 20% collagen coated group. Also, through western blotting techniques and immunofluorescence methods knockout of Myh10 protein was confirmed. Proteins specific to PCT cells including megalin (apical endocytic receptor) and SGLT2 (Na^+-sodium cotransporter) were visualized by immunofluorescence or analyzed by western blotting techniques. These cells will serve as novel renal epithelial cell models to facilitate our understanding of receptor mediated transport pathways unique to proximal tubular epithelial cells and its role in maintaining kidney function.

Science Education: Innovations in Undergraduate Teaching

P9/B9

Investigating Relationships among the Individual, the Team, Personal Strengths, and Peer Evaluation in a Team-based Introductory Biology Course.

D. E. Steen, Jr., **S. Wick**; University of Minnesota, Minneapolis, MN.

Team-based learning is an effective way to learn in STEM. We examined the relationships of team scores and individual scores and whether sex or personal strengths affect individual scores or team scores. In the team-based introductory biology course for majors we studied, semester-long teams collaborate daily on in-class activities, take weekly quizzes, and work on a semester long project. To encourage development of team skills and personal accountability, every week student roles on the team rotate and team members note each other's contributions. At the end of the semester students evaluate teammates' contributions. We collected data from 357 students in three course sections and analyzed elements of individual and team scores. To achieve a high degree of diversity on teams, we sorted

students based on apparent race and sex (from student pictures on course registration lists), honors status, geographic and cultural diversity, and personal strengths. We based geographic and cultural diversity on students' first language and on where they attended high school, reported on a pre-class survey. An other survey question asked them to identify a personal strength that we matched to the categories (Administrator, Artist, Communicator, or Expeditor) in Wright and Boggs 2003. At the end of the semester, team members indicated who exhibited traits characteristic of each personal strength category. • Individual and team scores were not correlated. • 23% of students earned a team score that negatively affected their final course grade percentage; only 1% of students earned a team score that negatively affected their final letter grade. • Men and women had no significant difference in scores. • Students identified by peers as Administrators and Expeditors have higher individual and peer evaluation scores. • Peer-evaluation score and team score were not correlated. • Peer-evaluation score and individual score were positively correlated. • Peer-evaluation scores were not different between men and women. • All teams identified individuals who contributed to teamwork according to each personal strength category. • Self-identified personal strength and team-identified personal strength often did not correspond. We conclude that a wide variety of students can be successful in this course, which emphasizes personal accountability and team skill development.

P10/B10

The Use of an Inquiry-based Laboratory Teaching Approach Using a Biofuels Assay.

F. Norflus; Clayton State University, Morrow, GA.

In order to engage students in biology laboratory classes, teachers attempt to make the material relevant and use an inquiry-based approach where students are responsible for designing their own experiments. This project discusses how the Bio-Rad biofuels kit (catalogue #1665035EDU) was used in a biotechnology class to show a real world example of biotechnology but also to teach students about designing experiments and interpreting data. Students were able to pick a parameter to test and also needed to trouble shoot the experimental details at certain points. The basics of this experiment is that the enzyme cellulase breaks down cellulose, found in plant cell walls, into glucose which can be further converted into ethanol during the process of fermentation. Since the enzyme cellulase is found in a few organisms including plants and fungi, this system could ultimately be used to develop biofuels as an alternate source of energy. In the class experiment, an artificial system was used. The enzyme cellobiase converts the artificial colorless substrate p - nitrophenyl glucopyranoside into the yellow colored product p-nitrophenol. The company provides purified cellobiase enzyme but it can also be obtained from an extract of mushrooms. Students used the company provided enzyme as well as extracts of different mushrooms and different parts of the mushrooms to determine which produced the most amount of cellobiase. Sample student data using enoki and shitaki mushrooms will be presented as well as suggestions on where students had difficulties with the experimental details and data analysis. The data shows that the mushroom extracts had greater enzyme activity than the purified enzyme provided by the company.

P11/B11

A Small Scale Novel Experimental Design Assignment as a Precursor to Cures Using Zebrafish as a Model System.

A. Dasgupta, S. Sarmah, J. Marrs, K. Marrs; IUPUI, Indianapolis, IN.

Scientific literacy or the ability to apply the processes of science was identified as one of six competencies outlined by Vision & Change (AAAS, 2009). The experimental design is a core scientific ability needed for a deep understanding of how biological knowledge is generated and gives students experience to formulate a plan to address a scientific question. Studies showed that early immersion into discovery-based research experiences, like experimental design, engages student during their undergraduate education (Elgin et al, 2016). One way to expose students to experimental design is participation in course-based undergraduate experiences (CUREs) (Dolan, 2016). While CUREs are an effective way to introduce a research problem to large student numbers, faculty might initially like to try small scale inquiry-based lab modules and gradually progress towards developing a CURE. In this project, we presented fall 2018 introductory biology students an opportunity to practice experimental design with an original lab module. The module centers on designing an experiment to study the effects of environmental toxins using zebrafish. Our assessment design focused on the following criteria: short term implementation; personal relevance to students; efficient use of limited resources; probing students' quantitative skills; open-ended with easy scoring for 300-600 students. With the aforementioned criteria, the module was organized to cover 2 lab sessions with 3 components namely: pre-reading, experience handling and imaging live and preserved zebrafish, and the experimental design exercise. Pre-reading, intended to level prior knowledge differences, involved primary literature readings to gauge the societal relevance of certain toxins, like alcohol and nicotine. Next, students were familiarized with the wild type and chemically treated zebrafish morphology differences in the lab. Last, students completed the experimental design assessment starting with the prompt: **How would you design a simple experiment to determine the effects of a particular compound of interest on zebrafish development or behavior?** Aligned with the basic competencies of experimentation, students were required to cover various aspects such as framing testable hypotheses, identifying experimental variables and prediction of experimental outcomes. Student responses were scored using the EDAT (Sirum & Humburg, 2011) and RED rubrics (Dasgupta et al., 2014). Our findings indicated the most common difficulties were manipulation of variables, measurement of outcome, and accounting for variability in the proposed hypothetical experimental plans. Positive outcomes regarding students' satisfaction with the modules is encouraging for us to continue implementation and assessment.

P12/B12

Effects of Guided Practice in Drawing on Model-based Reasoning and Use of Drawing for Studying.

J. R. Burns, P. D. Heideman; William & Mary, Williamsburg, VA.

Model building can use drawing or sketching (D/S) as a mechanism to help the drawer learn information (study), solve problems (model-based reasoning, MBR), and communicate. Unfortunately, many students fail to master D/S skills due to the effort and instruction required. We applied guided practice of D/S to an undergraduate first-semester Introductory Biology majors course, which focuses on the cellular and molecular basics. Using a combination of surveys and semi-structured interviews, we aimed to assess (1) how much students continue to use D/S as a study tool in subsequent semesters, (2) the extent of D/S usage for MBR, and (3) whether the use of D/S was correlated with correct answers on

exams. Students decreased their use of passive study methods during the course (pre: 56% to post: 37%; $P < 0.01$). Major changes included less visual review (from 38% to 25% of study time; $P < 0.01$) in studying and more D/S (pre: 13% to post: 42%; $P < 0.01$). In the pre-survey, only 5% of students listed D/S as part of their 'most effective' study method, rising to 33% in the post-survey ($P < 0.01$). Students who reported reluctance to change their study methods used less D/S while studying than those willing to change their study methods. During the class that assigned D/S for homework, over 90% of students interviewed used D/S when answering questions on assessments that did not require D/S, but < 1/3 used D/S for MBR. The following semester, when D/S was no longer taught in class, less than 20% used D/S on questions that did not require D/S. Data collection and analysis are ongoing for (2) and (3) above. These outcomes will be reassessed yearly. The results at the end of the first semester are unsurprising, as students were encouraged to draw for homework and exams. An important question for ongoing data collection is whether students continue to use D/S in subsequent semesters and in courses that neither require nor encourage drawing to learn. Our preliminary conclusion is that a course in this format can support development of D/S for MBR while developing more active study methods.

P13/B13

Engaging Students through Forensic Sciences and Using the Class-Bio Survey to Assess Student Attitudes and Beliefs About Learning in General Biology.

C. Jones; Lane College, Jackson, TN.

Lane College is a historically black college committed to educating underserved minority students. My objective was to give students a diverse teaching experience and improve student success in General Biology I by engaging students through forensic sciences. The study of forensic science has increased in popularity and given teachers a technique to teach biology, chemistry, and physics. I implemented forensic science in the laboratory in one of my two sections of General Biology I in the Fall 2018 semester. Students studied and determined the items that needed to be analyzed from a mock crime scene after being presented some basic forensic science techniques in the first week of laboratory. Each additional week the students participated in hair analysis, fiber analysis, soil analysis, synthetic blood tests, chromatography, and DNA fingerprinting. To measure the success of the intervention, I used CLASS-Bio Survey to assess student attitudes and beliefs about Learning (n=32) that was given pre and post to both sections as a way to compare the effect of the intervention. The pre survey perceptions were higher for the section that I was giving the Forensic Science intervention in all categories Enjoyment, Real World, Problem Solving Synthesis and Application, Problem Solving Effort, Conceptual, Problem Solving Strategies, and Reasoning. At the end of the course, the class that received the forensic science intervention had a 19.1% greater increase in Enjoyment, 15.9 % greater increase in Problem Solving Effort, and an 18.4 % greater increase in Problem Solving Strategies compared with the class that did not receive the intervention.

P14/B14

The Genomics Education Partnership: New Science Projects Expand the Opportunities for Student Participation in Genomics Research on the Evolution of Parasitoid Wasp Venoms and Insulin Pathways Genes.

M. S. Santisteban[1], M. Van Stry[2], A. G. Rosenwald[3], W. Leung[4], J. M. Braverman[5], N. T. Mortimer[6], L. K. Reed[7]; [1]University of North Carolina at Pembroke, Pembroke, NC, [2]Lane College, Jackson, TN, [3]Georgetown University, Washington, DC, [4]Washington University in St. Louis, Saint Louis, MO, [5]Saint Joseph's University, Philadelphia, PA, [6]Illinois State University, Normal, IL, [7]University of Alabama, Tuscaloosa, AL.

The Genomics Education Partnership (GEP) started in 2006 to introduce genomics in undergraduate classrooms/labs. Genomics provided an ideal means to involve large classes in authentic research with benefits similar to the wet-lab apprenticeship model, and at a low cost. The original scientific questions focused on the evolution of *Drosophila*'s Muller F element (dot chromosome) across multiple *Drosophila* species. Students at institutions ranging from community colleges to tier-1 research universities participate in improving the genome sequence and annotating the mostly heterochromatic F element and a euchromatic region near the base of the D element in different *Drosophila* species. These improved sequences and gene annotations have been used in four scientific publications. The GEP has grown to a network of more than 100 colleges and universities. To support future growth, the GEP has evolved from a centralized leadership model to a distributed leadership model, and has introduced two additional science projects: parasitoid wasp venom and biological pathway gene annotations. The parasitoid wasp venom annotation project aims to provide insights into the functions and evolution of venom genes. Current research has hinted at putative mechanisms of action, and it is expected that the improved annotation of venom genes produced by GEP students will help to characterize the functions of venom proteins, and to identify proteins with potential dominant negative functions. Similarly, understanding the genomic context of venom genes should help resolve questions concerning the evolution of venom genes. The pathways project uses network analysis approaches to elucidate the evolution and function of biological pathways, initially focusing on the insulin signaling pathway. Past studies have shown that the rates of evolution for the gene's protein-coding regions are correlated with its position within the network, the number of physical interactions, expression levels, and the existence of closely-related paralogs. GEP students will produce gene annotations for the putative orthologs and paralogs of *D. melanogaster* genes involved in the insulin signaling pathway in 27 *Drosophila* species. These improved gene models will be used to ascertain if the rates of evolution for the genes' regulatory regions parallel that of their protein-coding regions. These new opportunities expand both the range of scientific questions in which students may find particular interests, as well as the possibilities of pairing annotation projects with wet lab investigations. GEP is currently recruiting new members (http://gep.wustl.edu/help/contact_us). Supported by NSF IUSE-1431407 to Sarah C.R. Elgin, NIH 1R35GM133760 to NTM, NSF IUSE-1915544 to LKR, and NIH IPERT-1R25GM130517-01 to LKR.

P15/B15

Compass "Creating Opportunities for Students in Sciences" Program Heightens Awareness of Careers in Science for Underrepresented Students in Rural North Carolina.

M. Santisteban, R. Bullard-Dillard; University of North Carolina at Pembroke, Pembroke, NC.

The University of North Carolina at Pembroke (UNCP) was awarded an S-STEM program (*COMPASS: Creating Opportunities for Students in Sciences* (award #1356582, 2014-2019, $618,993). The program enrolled 27 talented students (3 staggered cohorts of 9 students each) with demonstrated financial need majoring in Biology (16), Chemistry (5), double Bio/Chem (4), and Biotechnology (2). The participant group (4 males and 23 females) was very diverse (36% Native-American, 32% African-American, 3% Latino, 14% Middle-East, 4% Asian-American, 11% white). Students received up to $6,000 a year from their sophomore to senior year. The program successfully met the goals of retaining and graduating students in a timely manner, preparing them successfully for careers in STEM through academic and career support programs, and fostering a community of faculty mentors and scholars. COMPASS scholars exceeded retention and 4-year graduation rates for general STEM students at UNCP (which were only 48% and 18.7% respectively at the start of our program). Twenty-five of the 27 scholars (92.6%) graduated in 4 years. One cohort III student graduated in 3.5 years, one graduated in 5 years because of a change of path. The program achieved an outstanding record of retention and graduation and COMPASS graduates demonstrated their growth when pursuing jobs and graduate school opportunities, including 64.7% of students who graduated with honors. Presently 41% of the students are in STEM related areas (PhD, masters, post-bac, teaching science or industry), many of them in NC. It became apparent to us that our talented students in Biology and Chemistry degrees overwhelmingly have goals of holding health related occupations, mainly MD, PharmD, PA, PT, and DVM. The program has been transformative for the lives and careers of these scholars and even those who persist in their plans to join a professional school recognize that COMPASS opened their eyes to careers and possibilities they did not know existed. In fact, the exposure to careers through site visits and conversations with STEM professionals was one of the most student-cited benefits of the program. Attending and presenting at professional conferences was also valuable and helped student's network and foster a sense of belonging in STEM. Being exposed to research experiences (77% participating) early on has also contributed to their openness to science careers. The community aspect is without a doubt the most valuable overall to all scholars. They all agreed that the program enhanced their sense of belonging to UNCP, and that the support of the COMPASS fellows was important to their academic success. The figure of the mentor not only was a source of support and integration within the program, but provided an additional source for academic advice and career support.

P16/B16

Enduring Use of Learner-generated Drawing to Learn Biology: Brief Intervention Versus Extended Practice.

P. D. Heideman, L. Wilkin; William & Mary, Williamsburg, VA.

Learner-generated drawings are useful for comprehension and model-based reasoning (MBR), but students struggle to represent biological structures, concepts, or hypotheses by drawing and sketching (D/S). Recent reviews emphasize that drawing and sketching as a skill is difficult to teach and difficult for students to learn. In this study, our objective was to test two approaches to develop enduring use of learner-generated drawing for studying and MBR. We hypothesized that students taught a method to

develop drawings that quickly represent structures or sequences of events might lead to enduring use of learner-generated D/S. In a prior study, we reported that a short D/S intervention with first-semester biology students improved recall and problem solving. In addition, 5 months after the intervention, students in the intervention reported increased use of D/S for studying (effect size = 0.67). Here, we ask (A) whether gains of D/S for studying were maintained for a longer duration, and (B) whether semester-long courses that taught, modeled, and encouraged D/S for comprehension and MBR might have similar or greater effects. The results showed (A) that gains from the short intervention were not maintained: in follow-up surveys conducted 2.5 and 3.5 years after intervention, participants matched the comparison group in D/S. (B) However, students who had taken 1-2 biology courses incorporating extensive instruction and applications of D/S for MBR reported, 1-2 years later, more use of D/S for studying than those in a comparison group (after 2 D/S courses: 23% of study time, and with no D/S courses: 6% of study time; effect size > 1) and were more likely to refer to drawing when describing their 'most important study method' (with no D/S courses:10%, and after 2 D/S courses: 52%). One-two years after their second D/S course, students reported using D/S in a median of 3 courses. A single D/S course had intermediate values for these measures. We conclude that a short intervention may be insufficient for enduring changes in use of D/S for studying, while engagement of students with D/S for MBR in semester-long courses may produce lasting changes in study behavior.

Drawing for Model-Based Reasoning: Problem-Solving and Performance on Exams in Integrative Biology and Cell Biology.

E. Arents, E. Gericke, C. Lott, P. D. Heideman; William & Mary, Williamsburg, VA.

Drawing and sketching (D/S) are well established as tools for learning and model-based reasoning (MBR), but students struggle to apply D/S for study and reasoning. We hypothesized that instruction in D/S with feedback and regular application in MBR and hypothesis testing would prepare students for MBR in subsequent courses. In a major's lecture course in integrative biology of animals (N = 150 students), we incorporated D/S for MBR. Materials included a conventional textbook, printed notes from the instructor, D/S instructional videos, and sketch uploads as homework. After exams, qualitative "think-aloud" interviews asked if and how students applied sketches to solve problems. During the integrative biology course, most students (80%) used sketches as a memory recall tool (e.g., 'a mental image'), just over half (57%) used sketches as an MBR tool when solving transfer problems on exams. The use of D/S was related to success on exam problems: for the answers analyzed, 81% of those receiving full credit had involved a sketch as a reasoning tool, while only 24% of answers receiving less than 2/3 credit involved a sketch as a reasoning tool. In a post-survey on usefulness of course materials, the second-most highly rated were D/S instructional videos. In a later cell and molecular biology course, students who had received extensive D/S instruction applied D/S both for studying and for MBR on exams. The results indicate that students given D/S instruction adopted sketching as a tool for learning, retrieval practice, and self-evaluation, and many successfully used sketches as mental models to solve difficult exam problems. We conclude that D/S can be incorporated into a large undergraduate course to develop MBR skills in biology students, and that students who received instruction continued applying D/S for MBR in a later course in molecular cell biology.

P18/B18

Analyzing Student Performance and Problem-solving Barriers in Open-ended Genetic Problems.

M. Crowder, 95616, V. Reddy; UC Davis, Davis, CA.

The need to build problem solving skills in STEM undergraduates has been widely reported. This study is part of a larger multidisciplinary investigation seeking to better understand undergraduates' STEM problem solving performance to develop a model that will guide instructional support of students' problem solving skill development. Specifically, the project is investigating the role of student knowledge structure, knowledge retention, and barriers in solving open-ended genetic problems. Study participants were enrolled in an upper-division genetics course that covers transmission, molecular, and applied genetics. This four unit course consists of two 110 minute lectures and an optional 50 minute discussion session each week of a 10-week quarter. 95% of the 293 enrolled students were majoring in STEM and required to take the course. To gather a baseline of students' genetics knowledge, ta Genetics Diagnostic Test (GDT) was administered to students in the first and last week of class. Students were also asked to complete an online Metacognitive Awareness Inventory (MAI) the first and last week of class. In addition to the CADEK and MAI, students answered open ended genetic problems on an in-class summative assessment, from which ten high performing and ten low performing students were identified and invited to participate in one hour think aloud interviews (TAInt). The TAInt were conducted during weeks 7 and 8 of the quarter and entailed participants speaking through their thought processes while solving several open ended genetic linkage problems. To assess levels of knowledge retention, participants completed a follow up TAInt 8-9 weeks after the end of course during which they solved the same open ended problems. Several developed instruments were used to analyze participant responses on the open ended genetic problems from the in-class assessment and transcribed TAInt. Specifically, the COSINE (Coding System for Investigating Sub-problems and the Network) method is an in-depth analysis of the difficulties students have during the problem solving process. To apply the COSINE method, sub-problems that correlate with specific steps of genetic linkage problems are assigned a code based on student performance on a particular task. Quantitative metrics are being developed based on resulting codes to provide insight into where and why students are unsuccessful, in addition to correlating student performance with incoming genetic knowledge, misconceptions, and metacognitive level.

P19/B19

Integrating Mathematics and Biology in the Classroom: a Compendium of Case Studies and Labs.

A. Walter[1], R. Sanft[2]; [1]St Olaf College, Northfield, MN, [2]University of North Carolina, Asheville, Asheville, NC.

We developed a compendium of exercises, cases and wet labs to support a mathematics of biology course that brings together undergraduate students from biology and the mathematical sciences. This book contains background exercises and case studies with real data and experimental labs that iterate through experimental design, data collection, analysis, and follow-up experiments. Difference equations and differential equations are introduced along with an R tutorial and embedded code throughout the text using examples from all levels of biological organization. At the level of cellular biology, we offer several exercises including tumor growth, enzyme function, an immune response, and quorum sensing. For the case on quorum sensing, we introduce the basic biology and system of autoinducers and response via the *lux* genes leading to phenotypic changes in the bacterial population. We then formulate a model of the sequential steps starting with bacterial population growth to the up-regulation of the *lux* gene, protein expression and the feed-forward responses. We explore the switch-like response to the

autoinducer through fitting the model to data from *Aliivibrio fischeri* using some known parameters and fitting others. Sensitivity analysis reveals the parameters with the greatest effects on response. Finally, we explore temporal aspects of the model and pose further biologically relevant questions for students to explore. The preparatory exercises, cases such as this one, and experimental labs together engender confidence in the ability of each student to address questions, both experimentally and mathematically, and highlight the value of working in interdisciplinary teams.

Sustained Mentorship Promotes the Development of Active Learning Strategies in Undergraduate Biology Classrooms: Evidence Gained from the Promoting Active Learning (PALM) Network.

S. Wick[1], **M. J. Wolyniak**[2]; [1]University of Minnesota-Twin Cities, Minneapolis, MN, [2]Hampden-Sydney College, Hampden-Sydney, VA.

Here we report on the work of the Promoting Active Learning and Mentoring Network (PALM), a National Science Foundation-supported project started in 2016 and dedicated to leveraging the expertise found in life science professional societies to provide long-term mentorship in developing active learning techniques in the classroom. PALM mentees work one-on-one with mentors that are seasoned in active learning strategies and travel to their mentor's institution to observe classes, plan modifications for their own classes, and strategize the best active learning techniques that are suited to their class' particular needs. A monthly online journal club and regular opportunities to meet in conjunction with the Society for the Advancement of Biology Education Research (SABER) and ASCB meetings provide a dynamic teaching and learning community for mentees and mentors alike. After their mentorship, mentees are encouraged to work with their colleagues on active learning strategies and to become a PALM mentor to further the spread of effective active learning strategies to an ever-wider audience. We have assessed the efficacy of PALM mentorship through the use of the Classroom Observation Protocol for Undergraduate STEM (COPUS) protocol (Smith *et al.*, 2013) on pre-mentorship and post-mentorship videos of mentee teaching. The COPUS results have revealed a consistent shift in mentee teaching practices from a strict focus on lecture to a more diffuse combination of classroom activities in which the student is more directly active and engaged in the class and the instructor is more directly engaging students in a more personalized manner. While the specific changes in classroom practice vary between individual mentees due to the distinct needs and environments of each class, there is a consistent picture of more student-centered classrooms that are more engaging and dynamic for both student and instructor. Overall, the COPUS data suggests that the long-term mentoring strategies brought forth by PALM are an effective and sustainable means to promote the development of active learning techniques among undergraduate biology instructors.

P21/B21

Mentorship in Converting Research into a CURE: the Mentoring the Integration of Research into the Curriculum (MIRIC) Initiative.

M. J. Wolyniak[1], K. K. Resendes[2], R. N. Crowder[3], L. F. Barton[4]; [1]Hampden-Sydney College, Hampden-Sydney, VA, [2]Westminster College, New Wilmington, PA, [3]Stetson University, DeLand, FL, [4]Austin College, Sherman, TX.

The American Association for the Advancement of Science (AAAS) *Vision and Change* document has spurred several initiatives designed to improve the way in which undergraduates learn science. Often,

these initiatives have been disseminated as one-time workshops that generate awareness of and interest in developing authentic research experiences for undergraduate STEM classrooms. Conversely, whole "standardized" curricula have been developed and made available for adoption. However, successfully generating the sustainable change necessary to bring real reform to undergraduate science education should benefit both students and faculty scholarship. To create sustainable change, long-term faculty development initiatives focused on mentorship are needed so that instructors can develop and implement sustainable curricula with local relevance. Experienced instructors seasoned in developing and implementing course-based undergraduate research experiences (CUREs) based on their own scholarship and local resources can convey their experiences to mentees interested in using these pedagogical techniques as the centerpiece of their own teaching. The Council on Undergraduate Research (CUR) Biology Division has created the Mentorship for Integrating Research Into the Classroom (MIRIC) program to provide a means for members with an interest in developing improved and sustainable active learning techniques to gain experience in this style of teaching through close, long-term interaction with a veteran teaching mentor. Developed from the former ASCB Mentorship in Active Learning and Teaching (MALT) program, MIRIC focuses on the development of instructors who wish to develop a dynamic CURE. Current and future life science instructors pair themselves up with seasoned veterans of CURE development and work with them and their students over the course of a semester or longer to develop a CURE that will allow the mentee to bring authentic research into his or her classes. In our pilot studies, we collected qualitative and quantitative data based on participant interviews and coding videos of student and instructor actions during classroom activity (Smith *et al*., 2013), respectively, that suggest that MIRIC mentorships have made positive gains in promoting sustainable active learning techniques among participants. Since then, we have surveyed the first cohort on both the success of their CURE development process as well as the benefits of the mentoring relationship on both the mentors and mentees using validated questions derived from Mathur (2012) and Pamuk and Thompson (2009).

P22/B22

Using modeling and animation to overcome previously-held misconceptions.

L. V. Paliulis; Bucknell University, Lewisburg, PA.

Modeling of biological processes through drawing or animation is a skill that can be key to understanding essential concepts in biology. In fact, the development and construction of models is an essential practice for meeting the Next Generation Science Standards (www.nextgenscience.org) for K-12 science education and a key core competency in Vision and Change in Undergraduate Biology Education (www.visionandchange.org). From early life science classes in elementary and secondary school through graduate education drawing and animation are used effectively to cement key concepts. Unfortunately, early use of incorrect drawings and models can lead to misconceptions and a lack of competency in foundational areas that are often retained. To study ways to overcome misconceptions in biology, I have focused on the intentional construction of new models following observation of videos of an actual cellular process. One foundational cellular process that students frequently model incorrectly is mitosis. Incorrect models of mitosis lead to incorrect understanding of errors made in mitosis and more complex phenomena such as meiosis; two key topics in the upper-level Cytogenetics class offered at Bucknell University. In an effort to replace incorrect models retained from earlier study of mitosis, students started the semester by producing a short animation of mitosis, showing their baseline understanding of the process. Students then watched time-lapse videos of mitosis, carefully comparing

their own animations to the videos of the process in living cells. This comparison showed that students' models were often inaccurate. Students then reanimated mitosis based on their view of the process in living cells. A quiz given at the end of the semester (two months later) showed that students retained what they learned from re-modeling mitosis after watching the process in living cells. I propose that careful reflection on misconceptions and combining observation of processes in life with re-modeling those processes can help students overcome previously-held misconceptions.

P23/B23

Science Education Videos Improve Student Performance in Non-major and Intermediate Biology Laboratory Courses.

L. Goudsouzian; DeSales University, Center Valley, PA.

Undergraduate biology laboratories emphasize hands-on skills. Descriptions of manual techniques required during laboratory instruction are often delivered via written instruction. We hypothesized that students who watch short, professionally produced high-quality instructional videos before performing a laboratory would achieve greater learning gains and self-efficacy than students whose pre-lab instruction was limited to handouts. We employed two videos in an intermediate molecular biology course at a small, liberal arts university and two videos in a non-majors biology course at a large, public research university. Both the videos and accompanying lab handout were assigned as a pre-lab assignment for 50% of the lab sections; the remaining 50% of the lab sections did not watch videos and only read the lab handout. A baseline survey assessment before the laboratory revealed no statistical difference between groups. Subsequently, both video and comparison groups were administered a pre- and post-lab exams. A post-lab self-efficacy survey was also administered to video groups. Our results reveal that in three out of the four laboratory classes, students who watched videos performed significantly better in both pre- and post-lab exams. For these students, we observed up to a two-fold increase in test scores on scientific concepts and techniques. For all four classes, 65-95% of the video group students reported that the video helped enhance their confidence, comprehension of concepts, and understanding of how to conduct the lab. We conclude that instructional videos can be used as an effective resource in enhancing existing curriculum of undergraduate science courses and significantly improving students' performance.

Making It Stick: the Story of CURE That Imparts Career Ready Skills.

J. B. Slee[1], M. Patel[2], J. S. McLaughlin[3]; [1]DeSales University, Center Valley, PA, [2]Medical College of Wisconsin, Milwaukee, WI, [3]Penn State - Lehigh Valley, Center Valley, PA.

Researchers have used THP-1 cells to study the host response to implantable devices and biomaterials in *vitro*. Tissue contacting surfaces of implantable materials initiate a host inflammatory response characterized by many events, one of which includes macrophage attachment to the surface leading to degradation and failure of the material. Utilizing an established THP-1 adhesion assay and four-step pedagogical framework, an eight-week CURE was implemented which allows students to participate in the scientific process by testing scientifically viable substances which may prevent the host inflammatory response to implantable devices and biomaterials. Importantly, the host response to implantable materials is a large healthcare burden and strategies to prevent it are currently being investigated. This CURE was successfully developed, implemented, and assessed over two semesters

and is now routinely implemented in a private four-year university and a satellite campus of a public four-year university. We set out to evaluate our CURE to see if this experience enhanced not only students' acquisition of needed "hard" skills deemed important for future work in cell biology research, but several top soft skills considered essential for the nation's overall workforce. What we discovered sheds light not only into these areas, but the indisputable significance of CUREs as a checkpoint experience for student reflection on career choice and a potential window of opportunity for faculty mentorship and guidance on workforce preparedness and career options.

P25/B25

Student Perceptions of Iteration and Collaboration in Research during Laboratory Courses.

L. L. Dahlberg[1], S. R. Lee[1], L. Lily[1], B. L. Wiggins[2], H. Sefi-Cyr[1], J. Rose[1]; [1]Western Washington University, Bellingham, WA, [2]University of Washington, Seattle, WA.

Two important aspects of Course-based Research Experiences (CUREs) are the opportunities to collaborate and opportunities to iterate in the laboratory. Previous studies describe in-lab collaboration as an important facet of CUREs. We designed and ran CUREs or CURE modules at three different levels of an undergraduate Biology curriculum—Introductory, Intermediate, and Advanced—in order to provide research opportunities at a primarily undergraduate institution that afforded meaningful collaboration to students at different stages of their undergraduate careers. Introductory-level students who participated in a short CURE module reported that repetition is an important part of Biological research more often than their counterparts in a control course. At the intermediate level, students ran quality control genotyping on samples provided by a large research-oriented (R1) university within existing course content. At the end of the quarter, students had the opportunity to re-run an experiment of their choice, including the collaborative CURE experiment. Focus group interviews suggests that the CURE itself, and its focus on collaboration, was less salient to students than the opportunity to revisit experiments or protocols. Finally, advanced level students who participated in an *intra*mural CURE across disciplines were exposed to the multi-level analysis approach that is common in many published research studies. We used portions of the Laboratory Course Assessment Survey (LCAS) as well as open-ended questions to probe students' attitudes about collaboration and repetition in research projects, and found that repetition was, again, a salient part of their research experience. Through these examples, we hoped to determine best practices for introducing realistic scientific collaboration into CUREs. Our preliminary results suggest that collaboration may change how students strategize about problem solving. However, iteration and productive failure may be more immediately important to students' approaches to research projects.

P26/B26

Development and Implementation of a Cell Culture Module: Investigating the Molecular Mechanisms Behind the Survival and Proliferation of Metastatic Ovarian Carcinoma Cells.

C. A. Davison-Versagli; Saint Mary's College, Notre Dame, IN.

Course-based undergraduate research experiences (CUREs) provide research opportunities for students, and students engaged in a CURE course display increased engagement and understanding of the flow of biological research. Furthermore, this course model provides an authentic research experience that better prepares students for graduate programs and careers in STEM. Cell culture-based research projects are being implemented into undergraduate classrooms to increase understanding of cell

biology research and promote proficiency in scientific techniques utilized frequently across industrial and academic biomedical research. Here, a new and unique 15-week 400-level CURE Cellular Physiology Laboratory was designed with the main objectives being to promote understanding of the flow of biological research and promote mastery of cell culture techniques. In this course, the following work flow was used: 1. students are presented with primary literature about a biological problem, 2. students develop a biological question and plan experiments, 3. students complete experiments and analyze, and 4. students collaboratively write a final research paper and give a research presentation. In this course, students were presented with current research in epithelial ovarian carcinoma, a form of cancer that has a relatively low survival rate because it is often diagnosed after it has already progressed to stage III or stage IV. Thus, a better biological understanding of the disease could lead to improved treatments and higher survival rates. Through reading, students discover that in order for cancer cells to spread (or metastasize) to regional and distant sites, epithelial ovarian carcinoma cells must be able to overcome extracellular matrix (ECM)-detachment-induced effects, including combatting increased reactive oxygen species (ROS). In the Spring 2018 iteration, students worked collaboratively as a group to investigate the role of Peroxiredoxin 1 (PRDX1) in the survival and proliferation of ECM-detached ovarian carcinoma cells. Students learned and utilized cell culture techniques, including trypan blue exclusion assays, soft agar assays, and immunoblotting. After completion of experiments and analyses, students completed a final research paper and final research presentation. Students reported increased passion and understanding for cell biology. Observations suggest that students had an increased understanding of the flow of biological research and confidence in performing cell culture techniques by the end of the course. In conclusion, these results suggest that the objectives for the course were met. In the future, this course will be improved and enrollment expanded to provide more opportunities for cell culture-based research to students.

New Techniques in Light and Electron Microscopy

A Note on Cell Fixation Using Formaldehyde Or Paraformaldehyde.

M. Hammer, S. Flemming, D. Grunwald; UMASS Medical School, Worcester, MA.

A Note on Cell Fixation using Formaldehyde or Paraformaldehyde Mathias Hammer[1,2], Selene Flemming[1], David Grunwald[1] [1] RNA Therapeutics Institute, University of Massachusetts Medical School, Worcester, MA, USA [2] FB Biology, Technical University Darmstadt, Darmstadt, Germany E-MAIL: david.grunwald@umassmed.edu KEYWORDS: formaldehyde, smFISH, nucleus, membrane, microscopy, refractive index Cell fixations are nearly as old as microscopy. They have given us the ability to investigate the structures of cells, their compartments and to develop techniques like smFISH, which allow the study of intracellular interactions on a molecule level. These studies have resulted in the development of our understanding of life and its architecture. Over 20 years ago it was found that fixation with para-/formaldehyde influences the shape of the cell membrane**[1]**, still para-/formaldehyde is currently being used as fixative in many labeling protocols and the vast majority of FISH protocols. To investigate the effects that this type of fixation has on cell shape and subcellular structures, we used series dilutions of para-/formaldehyde on living cells and observed the 3D shape and changes in the refractive index of subcellular compartments in real-time using a new kind of microscopy technique**[2]**. We find that the cytoplamsic membrane builds up bubbles upon treatment with para-/formaldehyde.

These bubbles extend for x-y minutes and are easily removed during sub-sequent washing steps. In parallel subcellular structures show massive changes in their shape and refractive index, which includes changes to the shape of the nuclear membrane and the inner nuclear structure. We present a method that prevents these changes to the cell morphology by modifying the media composition through addition of iodixanol. [1] Brock R, Hamelers IH, Jovin TM. Comparison of fixation protocols for adherent cultured cells applied to a GFP fusion protein of the epidermal growth factor receptor. Cytometry. 1999 Apr 1;35(4):353-62. doi: 10.1002/(SICI)1097-0320(19990401)35:4<353::AID-CYTO8>3.0.CO;2-M. PubMed PMID: 10213201. [2] Cotte Y. Toy F, Jourdain, P, Pavillon N, Boss D, Magistretti P, Marquet P, Depeursinge C. Marker-free phase nanoscopy. Nature Photonics. 2013-02;7:113-117. doi: 10.1038/nphoton.2012.329.

P28/B29

Application of Advanced Microscopy Technology in Cell Biology and Disease Study.

A. Liang[1], C. Petzold[1], K. Dancel-Manning[1], C. Zhou[2], P. H. Ren[3], R. Lehmann[1], M. Delmar[1]; [1]NYU Langone Health, New York, NY, [2]Concord Academy, Concord, MA, [3]Stuyvesant High School, New York, NY.

Recent advances in microscopy have led to the development of technology and instrumentation, capable of achieving higher resolution from centimeters to angstroms. However, optimal preservation of biological specimens remains a challenge. As a research driven microscopy core facility, our goal is to identify methods that offer superior preservation for a wide spectrum of samples through experimentation. These innovations, combined with the application of various advanced microscopy technologies, allow us to serve the interests of researchers from multiple disciplines, from developmental biology to disease study. T cells are specialized lymphocytes that play a central role in cell-mediated immunity, including antiviral immunity. Studying morphological changes in mitochondria of T cells in cancer mouse models, is an important aspect of cancer research. However, preserving tiny amounts of flow-sorted T cells from mice for ultrastructural study, is technical challenging. We use a modified protocol, reduced osmium-thiocarbohydrzide-osmium (rOTO), with additional uranyl acetate and lead aspartate staining, to further increase heavy-metal content, such that the membrane structure of T cell mitochondria is greatly enhanced. This *en bloc* staining method can also provide high contrast, increase sample conductivity, and reduces charging issues during serial block face scanning electron microscopy (SBF-SEM) imaging. A similar sample processing approach was used to study host cellular compartments that serve as *Wolbachia* niches. The rOTO protocol produces a clear outline of *Wolbachia*, which makes it much easier to distinguish the membrane of *Wolbachia* from other cytoplasmic organelles in both cultured JW18 cells and the ovary of *Drosophila*. SBF-SEM results provided strong evidence that *Wolbachia* reside intracellularly, within modified host endoplasmic reticulum niches. Arrhythmogenic cardiomyopathy (AC; also known as ‘arrhythmogenic right ventricular cardiomyopathy’ or ‘ARVC’) is an important cause of sudden cardiac death in young people. AC is a genetic cardiomyopathy where most of the disease-causing mutations occur in proteins that form part of the desmosome, such as plakophilin-2 (PKP2). The relationship between PKP2 and connexin 43 (Cx43), a primary component of gap junctions, is key to the pathogenesis of AC. By combining single molecule imaging technology, correlative light and electron microscopy and three-dimensional electron microscopy, we demonstrated that the outer edge of Cx43 crosstalk with PKP2 clusters, and the dimension of these clusters depend on an kyrin G expression. We also demonstrated that $Na_v1.5$ molecules are major contributors to cardiac sodium current, and loss of $Na_v1.5$ expression reduces intercellular adhesion strength.

P29/B30

Scale-free Tracking Microscopy of Freely Suspended Cells: Towards Connecting Cell Biology and Ocean Ecology.

D. Krishnamurthy[1], H. Li[1], A. Larson[1], D. Mion[2], E. Li[1], F. B. D. Rey[2], M. Prakash[1]; [1]Stanford University, Stanford, CA, [2]Ecole Polytechnique, Paris, FRANCE.

Many cells spend their entire lives freely-suspended in a fluid, rarely encountering any substrate. Uni-cellular marine plankton epitomize this lifestyle, where single cells can travel several tens to hundreds of meters vertically in the water column, as part of the largest daily bio-mass migration on our planet. Such migrations are key components of vertical material fluxes in the ocean and drive planetary-scale biogeochemical cycles, and form a major component of oceanic carbon sequestration. Measuring sub-cellular-scale processes in single cells while allowing free movement over ecological-scale distances is, therefore, crucial for mechanistically understanding the cell biology and ecology of the living ocean. However imaging over large distances along the axis of gravity is a considerable challenge for conventional microscopy: Given the tradeoff between optical resolution and field-of-view, how can one measure single organisms or cells, at microscale resolution, while allowing them to freely move hundreds of meters in the vertical direction? Here we present a solution in the form of a scale-free, vertical tracking microscope, based on a circular “hydrodynamic-treadmill” for single cells, with no bounds for motion along the axis of gravity. Our method demonstrates a new paradigm for simultaneous multi-scale measurement where microscale characteristics like cell-state and organismal behavior can be directly connected to macroscale outcomes like depth in the water column. Using our tool, we demonstrate novel biophysical measurements in two classes of ecologically relevant plankton. In single-celled diatoms spanning four species, we discovered rapid density fluctuations over millisecond time-scales by concurrently measuring cell behavior (vertical sinking speed) and cell’s molecular state by synthesizing our tracking microscopy method with fluorescence imaging of signaling reporters. In the dinoflagellate cells *P. noctiluca*, we observed, for the first time, cell-division in suspension, far from substrates and resolve microscale fluctuations in cell density during division and rapid changes in cell volume post-division. Finally, we combined our tracking methodology with environmental patterning of light, chemical species and ambient pressure to bring the virtual-reality paradigm, which is well-established in neuroscience, to cell biology in the ocean. We anticipate that our method will open up new avenues for understanding key biophysical processes in our oceans at sub-cellular resolution, and allow connections between cell biology and ecology. Beyond the oceans, we foresee that our method will allow novel cell-biological measurements by freeing cells from the confines of the coverslip.

P30/B31

Local Surface Plasmon Resonance of Gold Nanoparticles as a Correlative Light and Electron Microscopy Tag.

T. Haruta, K. Hasumi, Y. Ikeda, Y. Konyuba, T. Fukuda, H. Nishioka; JEOL Ltd., Akishima, JAPAN.

Correlative light and electron microscopy (CLEM) is powerful method to reveal the relationship between nano structures and functions in cells. We previously reported the CLEM of optical microscopy (OM) and transmission electron microscopy (TEM) using a silicon nitride (SiN) film. The same sample mounted on the SiN film could be observed seamlessly by OM and TEM using an exchangeable retainer. However, this method had some limitations for applications to biological samples. For example, more stable

fixation of samples was needed for TEM using strong fixatives (glutaraldehyde and osmium tetroxide), which usually reduced or quenched the fluorescence of fluorescent proteins or dyes. Furthermore, thin sectioning of the samples was required to transmit the electron beam (about 100 nm less). As a result, these thin samples contained little fluorescent substances, resulting in very low image contrast of OM. In other words, a new tag for OM, which is resistant to crosslinking by aldehyde and oxidation by osmium tetroxide and possesses strong luminescence properties from small volumes, is required to apply CLEM to biological samples. In this study, we investigated application of localized surface plasmon resonance (LSPR) of metal nanoparticles (NPs) to the CLEM tag for biological samples. The optical properties of metal NPs are determined by the interaction of electrons and light near their surface. When metal NPs are irradiated with light, collective oscillation of electrons near the surface of metal NPs occur. This collective oscillation of electrons by light is LSPR. LSPR causes strong absorption and scattering light at specific wavelengths. This wavelength strongly depends on the kind, size, shape, surface modification, and aggregation state of metal NPs. As results of investigations, Gold NPs in ultra-thin sections for TEM revealed that LSPR could be observed by optical microscopy when those sizes of 20 nm or greater. Gold NPs at sizes less than 20 nm could be observed using the gold enhancement method. Therefore, this CLEM tag could be applied to immunoelectron microscopy using this gold enhancement method. These results suggested that gold NPs were useful as a CLEM tag for biological samples.

P31/B32

An Elemental Approach to Semi-automated Segmentation of Organelles in Three-dimensional Scanning Electron Microscopy Enables Rapid an alysis of Cell Ultrastructure.

L. C. Hughes; OXFORD INSTRUMENTS, INC., High Wycombe, UNITED KINGDOM.

Three-dimensional (3D) scanning electron microscopy (SEM) techniques such as serial block face scanning electron microscopy (SBFSEM), focused ion beam scanning electron microscopy (FIBSEM) and array tomography produce increasingly large datasets with an immense amount of information. The applications for 3D SEM have broadened beyond the neurobiology and connectomics fields to other areas of biology, including cell biology in a diverse range of species (Borrett and Hughes, 2016). An alysing these datasets is a huge undertaking, with the major resource bottleneck being researcher time (Peddie and Collinson, 2014). Selective staining techniques can aid in rapid analysis by enabling researchers to threshold data based on stain intensity (Kittelmann *et al*., 2016), but there are a limited range of stains that can specifically target regions or organelles of interest and the technique is hampered by the inclusion of artefacts at similar greyscale thresholds. The aim of this investigation was to test if elemental analysis using energy dispersive X-ray spectrometry (EDS) could be used to identify endogenous elements and stains in biological samples and separate them from common artefacts. A model system of liver tissue was used to examine if elemental mapping could be used in combination with array tomography to generate element-based masks for semi-automated segmentation of image data. Liver tissue was prepared using standard fixation and staining techniques for transmission electron microscopy. Serial sections were cut at a thickness of 100nm and collected onto carbon coated Kapton tape. Array tomography was used to collect BSE images and EDS maps of whole hepatocytes. EDS maps were used to produce 3D masks, differentiating between lipid droplets and similar greyscale structure within cells. The masks were applied to 3D array tomography datasets, enabling volumetric and quantitative analysis in a shorter amount of time than the equivalent manual segmentation. EDS in combination with 3D SEM techniques can be used to produce element-based masks rapid and semi-

automated segmentation of backscattered electron (BSE) image data. Borrett, S. An d Hughes, L., 2016. CryoAPEX Paves the Way for the Discovery of an Unconventional Membrane Transport Pathway Induced by Alphaviruses.

R. Sengupta, S. Poudyal, R. J. Kuhn, R. V. Stahelin; Purdue University, West Lafayette, IN.

The determination of specific localization of proteins in *situ* at a high resolution is the first step towards comprehensive understanding of form and function within the subcellular landscape. However, available electron microscopy methods exhibit inadequate ultrastructural preservation leading to incomplete and artifactual localization data from attempted 3D reconstructions. Our recently published method, CryoAPEX exhibits excellent ultrastructural preservation and enables localization of a protein in 3D via EM tomography by coupling peroxidase (APEX2) tagging and cryofixation of cells using high pressure freezing. The method thus closes the gap in understanding the critical processes within cells during endogenous or pathogenic events that results in the morpho-functional remodeling of membranes and organelles. The work depicted here exhibits the application of CryoAPEX to dissect the trafficking of envelope glycoprotein (E2) of an alphavirus, a plus-strand RNA arbovirus. Although, a well-studied virus, the details of the membrane trafficking of the alphavirus E2 in its mammalian and mosquito hosts remains unclear. Here we morphologically dissect the trafficking pathway of E2 in mammalian and mosquito cells by constructing a virus with the APEX2-peroxidase gene inserted in-frame within the E2 gene. This study reveals that the virus remodels the Golgi apparatus and engineers an unconventional membrane transport system for the trafficking of E2 from the Golgi to the plasma membrane, the site of its egress. We identify mutations that results in abrogation of a morphological subclass within these pleomorphic transport vesicles resulting in a sharp drop in virus egress. Thus we show that though these vesicles originates from the same organelle they are born out of distinct mechanisms. We further show that these transport intermediate undergoes a morphological flux as the infection progresses resulting in complete remodeling of the Golgi apparatus. We also used APEX2-tagged organelle markers in parallel to ascertain the origin of these pleomorphic transport intermediates at various stages of infection. In summary, this work showcases a powerful application of CryoAPEX in the discovery of a pathogen induced unconventional trafficking pathway and paves the way for such future discoveries in disease and microbial pathogenesis.

Pharmacy, Yeungnam University, Daehak-ro 280, Gyeongsan-si, Gyeongsangbuk-do, South Korea, 38541
the stressosome complex is a virus-like capsid macromolecules that is activated in response to diverse environmental stresses including heat, ethanol and osmotic shock. It is known that the macromolecule is directly involved in the upregulation of Sig*B*-dependent transcription pathway. Previous studies demonstrated intramolecular self-assembly within the complex under symmetry reconstruction of cryo-EM, however the structural details in assembly of stressosome is still unclear. Here, we present reliable assembly model of the RsbRA/RsbS stressosome complex based on the crystal structure of RsbS icosahedron with cryo-EM structure under symmetry and symmetry-free reconstructions determined at 4.1, 7.1 and 9.1 Å, respectively. The crystal structure formed 60 monomers for RsbS fitted well into the electron densities of icosahedral cryo-EM model. Furthermore, the RsbRA dimers of 22 protrusions were also observed in the envelope of symmetry-free reconstruction map. Following these suggestive results, our study can aid further structural investigation of various types of stressosome complexes and answer unsolved questions about the stressosome in the coming future.

Multi-patterned Phase Target to Benchmark Phase Contrast-based Microscopies of Cell Cultures.

A. W. Peterson, E. J. Kwee, M. Halter, L. Yu, J. T. Elliott; National Institute of Standards and Technology, Gaithersburg, MD.

Phase contrast microscopy is routinely used to monitor cell cultures in academic, commercial and government laboratories. Because it is a non-destructive imaging technique, phase contrast evaluations of cell cultures can be used to make critical decisions about whether to harvest cells or to change growth conditions. A challenge with conventional phase microscopy is that cellular evaluations are qualitative and can be difficult to reproduce due to the complexities of the optical train in the microscope setup. For commercial applications of cells, such as in therapies and biotechnology, quantitative and non-invasive strategies to evaluate cell culture are required. Quantitative phase imaging (QPI) is an emerging imaging modality that can address this gap in phase contrast microscopy. QPI enables quantitative measurement of the optical pathlength difference created as light passes cells. There is a lack of reference materials and protocols to enable comparability and assure reproducibility of the imaging results. To ensure confidence in the QPI techniques, we present a quad-patterned glass etched glass target with optical features (sizes and phase shifts similar to mammalian cells) as a prototype physical standard to benchmark the performance of phase contrast microscopy and QPI. The quad-pattern target contains 1) a featureless flat region of glass (< 2 nm roughness), 2) a lateral grating with 40 µm period and 500 nm step height, 3) a square grid of cylindrical features with discrete optical volumes (150 μm^3), and 4) a Siemens star resolution target with measured spatial resolution down to 360 nm. We have characterized both the physical height and optical pathlength difference of the optical features, and the spatial resolution of the quad-patterned material with orthogonal measurement systems. We present cell imaging examples for both phase contrast microscopy and QPI that show how to use our reference material to rectify a misaligned phase ring for phase contrast or an incorrectly set condenser aperture for QPI. This type of material may be useful for the emerging growth area of label-free nondestructive live-cell imaging and could serve the measurement assurance needs for quantitative cell biology in the engineering biology and healthcare fields.

Universal EM Connectomic an alyses by Deep Learning Powered App-matching Image Conversion.

H. Sasaki[1], C. Huang[1], W. Yu[2], R. Wong[3], L. A. G. Lucas[1], **S. Lee**[1]; [1]DRVision Technologies LLC, Bellevue, WA, [2]University of Washington, Department of Biological Structure, seattle, WA, [3]University of Washington, Department of Biological Structure, Seattle, WA.

Deep learning (DL) is emerging as a powerful tool that has attracted a lot of interest in microscopy image analysis. Using deep learning for automated 3D EM image boundary detection is a promising new development. However, this technology is currently only used by a small number of pioneering research groups. This is largely due to four major practical hurdles: (1) the requirement for multiple highly specialized and disjointed software libraries or tools to cover the entire DL train-apply workflow; (2) the need to have extensive expertise to fine-tune the training process; (3) the need to access high-performance hardware to train DL networks, and (4) the difficulty and time-consuming process of ground truth (GT) creation. Furthermore, the resulting deep models are specific to the trained experimental and imaging conditions (called “domain”) and are not readily applicable to images from other domains without significant re-training. We are developing a novel deep learning powered app-matching image conversion framework that converts images from a new domain to mimic the images from the domain where an application model (called “App”) is created and validated. Therefore, the validated App from a training domain can be applied to a new domain by converting new domain images to the training domain. This renders the App universally applicable without new domain specific re-training. We validated the app-matching image conversion framework in the 3D EM image boundary detection applications. A U-net (the App) is trained to segment 3D neurites in EM images from the ISBI 2013 challenge (the training domain). The App is applied to new EM images acquired at the Rachel Wong Lab from the University of Washington (new domain). The new domain images are converted through app-matching image conversion and then the App is applied. The results are close to a new U-net specifically trained using the new domain data. Furthermore, we demonstrated that the app-matching image converter can be trained with as few as a single image from the new domain. This represents a significant advantage in practical applications. We are working on application enhanced conversion and artifact rejection that should further improve the applicability and performance of our novel app-matching image conversion framework.

***In Situ* Measurement of Protein and Lipid Mass by Normalized Raman Imaging.**

S. Oh[1], C. Lee[1], D. Fu[2], W. Yang[3], A. Li[1], C. Ran[4], W. Yin[4], C. J. Tabin[1], S. Xie[5], M. W. Kirschner[1]; [1]Harvard Medical School, Boston, MA, [2]University of Washington, Seattle,, WA, [3]Harvard University, Cambridge, MA, [4]Massachusetts General Hospital, Boston, MA, [5]Peking University, Beijing, CHINA.

Cell growth is the basis for myriad biological processes ranging from development, regeneration and tumor growth. Diverse extracellular signals such as growth factors, hormones, nutrients, and cell-to-cell contact are transduced by the signaling pathway to regulate growth. Yet it is still an open question how the integration of diverse inputs results in cell growth or maintains cells at the right size in the face of massive protein turnover. Accurate measurement of cell size is critical for probing these questions. State-of-art techniques such as quantitative phase microscopy, suspended microchannel resonator, and novel fluorescence reporter made it possible to measure cellular dry mass in higher precision and throughput than ever. Nevertheless, the existing methods require suspended cells or in vitro cell

cultures by which the contextual information of the tissue is lost. While the cell volume can be measured by confocal microscopy, there is no existing method to measure cellular dry mass or protein mass in *situ*. Here we present Normalized Raman Imaging (NoRI) that fills the technology gap by providing the absolute concentrations of total protein, total lipid, and water of cells and subcellular compartments in *situ*. NoRI achieves the absolute quantification by combining Stimulated Raman scattering (SRS) microscopy with a novel computational algorithm that removes the effect of light scattering in thick tissue samples. NoRI is a label-free technique that can measure live or fixed tissue sections, cultured cells and small model organisms without any use of staining. The single cell protein mass and lipid mass can be acquired by integrating the respective concentrations over the cell volume. NoRI reveals that cell types and tissue types have characteristic protein and lipid density, which may change with developmental or disease processes, and opens a door to many interesting questions about the regulation of cell growth in tissue context.

Optimization of Quantitative Phase Microscopy Reveals Autonomous Growth Rate Oscillation in Mammalian Cells.

X. Liu[1], S. Oh[1], T. P. Miettinen[2], J. H. Kang[2], S. R. Manalis[2], M. W. Kirschner[1]; [1]Harvard Medical School, Boston, MA, [2]Massachusetts Institute of Technology, Cambridge, MA.

Growth is a fundamental property of cell physiology. However, the understanding of its regulation in mammalian cells has been thwarted by the difficulties in growth rate measurement at the single-cell level. Here we report an optimized Quantitative Phase Microscopy (QPM) for longitudinal and large scale measurement of cell growth in adherent cells by improved image processing algorithms and automated cell tracking software. The measurement accuracy is improved by more than two folds. Using the new system, we reveal a remarkable growth rate oscillation throughout cell cycle in several different cell lines, which is independent of cell cycle progression but coupled to cell division. The growth rate oscillation may be a general feature of mammalian cell growth regulation.

P38/B39

Correlative Transformation and Visualization Tool for Correlative Light-electron Microscopy (clem) analysis.

C. Huang[1], W. Yu[2], H. Sasaki[1], R. Wong[2], **S. Lee**[1], L. A. G. Lucas[1]; [1]DRVision Technologies LLC, Bellevue, WA, [2]University of Washington, Department of Biological Structure, Seattle, WA.

Recent technological advancements in microscopy techniques, labeling methods, preparation procedure, data analysis informatics and computing infrastructures have made high-resolution imaging and visualization of large tissue blocks a possibility. Armed by the promising advancements in elucidating and quantifying the connectomics of brain networks with subcellular resolution using electron microscopy (EM). There are increased interests in hybrid approaches correlating functional fluorescence microscopy data and ultrastructural information from EM in a common biological context, correlative light electron microscopy (CLEM). We are developing a correlative transformation and visualization tool to perform automated image registration for CLEM analysis. General purpose landmark and intensity-based image registration approaches were implemented to register a LM image with a corresponding EM image. Both rigid registration and non-rigid registration methods were developed and applied to the CLEM dataset for comparisons. The 3D image viewer supports correlative

visualization of 3D LM and EM volumes in a single window. The functionality of clipping/orthographic planes enables viewing of the volume cross sections in the X, Y, and Z directions, or in any arbitrary orientations. This feature becomes very useful when certain objects could only be observed or found in a certain orientation. We validated the correlative transformation and visualization tool using a retina CLEM dataset acquired at the Wong Lab. The tool is integrated with the 3D visualization environment in Aivia for fast viewing of registered LM and EM volumes. This greatly speeds up the studies for neuron circuitry identification and novel cell type discoveries. We will continue to improve the correlative transformation and visualization tool in an Aivia prototype by introducing more 3D visualization options and adding support for measurements and data structures for correlative studies.

Modeling the Relationship between Cell Size and Division Number in Chlamydomonas Using a Stochastic Hybrid System Approach.

D. Liu[1,2], C. Vargas García[3], A. Singh[4], J. Umen[1]; [1]Donald Danforth Plant Science Center, Saint Louis, MO, [2]University of Missouri, St. Louis, Saint Louis, MO, [3]Fundación Universitaria Konrad Lorenz, Bogotá, COLOMBIA, [4]University of Delaware, Newark, DE.

Active maintenance of cell size through homeostatic mechanisms is thought to promote fitness in proliferating cells. Size homeostasis in green alga Chlamydomonas is under the control of both “Sizer” and “Timer” mechanisms that govern its multiple fission cell cycle. In multiple fission cells alternate between a prolonged G1 phase during which daughters may enlarge many-fold in size, and a division phase with rapid alternating rounds of DNA synthesis and mitosis (S/M phase). The “Sizer” governs the minimum size a cell must reach in order to transition into S/M phase, and it determines how many rounds of S/M a mother cell will undergo such that daughter size distributions are uniform. The “Timer” enforces a five to eight hour delay between reaching the minimum size for division and entering S/M phase. The ability to control the extent of growth in G1 phase using duration/intensity of available light in phototrophic cultures enables production of different sized mother cell populations. It is well established that larger mother cells divide more times on average than smaller mother cells so that daughter populations are uniform regardless of the size of the mother cell population that produced them. While, on a population level, cell division behavior is reproducible, on a single cell level there may be stochastic variability whose origins and contributions to size homeostasis are not well understood. We established a microscopy-based method to track the relationship between cell size and division number in individual cells. We found that while in general, larger mother cells divide more times than smaller mother cells, individual cells of the same size do not always divide the same number of times. Reciprocally, when grouped by cell division number, mother cells that produced a given number of daughters (e.g., 2, 4, 8, and 16) occupied a range of sizes that often exceeded the two-fold range which would be expected if the mitotic sizer mechanism operated perfectly. We are using modeling and simulation approaches to investigate how stochastic behaviors at the single cell level in Chlamydomonas can lead to predictable and uniform behavior at the population level. Empirical statistical properties of the relationship between cell size and division number are fit into the probability models. Stochastic hybrid models can be used for these simulations and will help determine whether the same set of

stochastic parameters rules govern size control in haploid versus diploid cells or in mutants that are defective in cell size control.

P40/B41

Manipulation of Cellular Rna Using an Artificial Rna Binding Protein.

Y. Yagi[1,2], T. Nakamura[1,2]; [1]EditForce inc., Fukuoka, JAPAN, [2]Kyushu University, Fukuoka, JAPAN.

Engineering of protein that target specific DNA sequence is expected as a useful tool for genome editing technology. Although genome-editing technologies have been established, the protein engineering that targets a particular RNA is still infancy. The PPR (pentatricopeptide repeat) motif-containing protein is a sequence-specific RNA binding protein family, and involved in multiple aspects of organelle RNA metabolisms. PPR proteins consist of a tandem array of PPR motifs (degenerated 35 amino acids) in variety repeat length (2-27 repeats). We solved the PPR-RNA recognition mechanisms: one PPR motif corresponds to one nucleotide, and the RNA nucleotide specificity is determined by the combination of amino acids at three particular positions within a motif. Using the knowledge of mechanism of PPR and RNA binding, we are able to create the various artificial sequence-specific RNA binding protein. Here we show the binding performance of our artificial PPR protein and its application to manipulate cellular RNA. First of all, we developed the efficiently PPR cloning systems, and could construct PPRs that contain various number of PPR repeats. Designed PPR proteins for 23 kinds of target sequences were constructed and analyzed their binding affinity and specificity. The results of binding affinity of all combination among PPRs and RNAs indicated that a sequence-specific RNA binding protein could be created with a construction probability of 80%. Using this artificial RNA binding protein, we developed a cellular RNA manipulation tool that control alternative splicing. In order to test whether designed PPR protein can control splicing through the binding to target RNA sequence of pre-mRNA in the cell, target sequences were selected from exon or intron of the splicing reporter, and their PPRs were constructed. Co-transfection of splicing reporter and PPR expression plasmid in HEK293T cell showed that target-specific binding artificial PPR protein can change the skipping ratio of target exon. Moreover, this PPR tools could be alter the amount of splicing variants of an endogenous RNA in the mammalian cell. Thus, our PPR technology would be useful to manipulates the splicing in the cell.

P41/B42

Immuno-SABER Enables Highly Multiplexed and Amplified Protein Imaging in Tissues.

S. K. Saka[1,2], Y. Wang[1,2], J. Kishi[1,2], B. Beliveau[3], G. Pihan[4], P. Yin[1,2]; [1]Harvard Medical School, Boston, MA, [2]Wyss Institute for Bioinspired Engineering, Boston, MA, [3]University of Washington, Seattle, WA, [4]Beth Israel Deaconess Medical Center, Boston, MA.

Mapping the molecular composition of individual cells in their native environment is critical to understand the cellular and subcellular organization of tissues in healthy and diseased states. However, conventional fluorescence imaging methods offer limited (typically <5) multiplexing due to spectral overlap. Sensitivity is the other limiting factor owing to high autofluorescence and scattering in the tissue samples, making it difficult to visualize low abundance targets. To achieve the desired high sensitivity and throughput, a clear need exists for a robust and scalable signal amplification method compatible with rapid multiplexing. To address this challenge, we developed a new in *situ* protein imaging method, **Immunostaining with Signal Amplification by Exchange Reaction (Immuno-SABER)**[1]. To simultaneously achieve high multiplexing and sensitivity, SABER[1,2] leverages: **1)** Multiplexing via DNA-

Exchange-Imaging (DEI) that enables fast and spectrally-unlimited imaging through single-step immunostaining with DNA-barcoded antibodies[3]. **2)** a new in *situ* signal amplification method, based on Primer Exchange Reaction, can autonomously synthesize long single-stranded DNA concatemers from short primer sequences using a novel catalytic DNA hairpin structure in a pre-programmed fashion[4]. SABER offers independently programmable signal amplification without in *situ* enzymatic reactions, and intrinsic scalability to rapidly amplify and visualize a large number of targets. We validated SABER for imaging of proteins in diverse sample types including cells, cryo and FFPE sections, and whole mounts. We demonstrated tunable 5 to 180-fold amplification, covering the full signal range conventionally achieved by secondary antibodies to tyramide signal amplification, as well as simultaneous signal amplification for 10 different proteins using standard equipment and workflows. We further combined SABER with Expansion Microscopy to enable rapidly multiplexed super-resolution tissue imaging. Immuno-SABER presents an effective and accessible platform for multiplexed imaging of proteins with high sensitivity and throughput, and is applicable for a broad range of applications including molecular atlases, biomarker discovery, and digital pathology. Granger-causality Network Inference Identifies Functional Relations among Redundant Actin Modulators in Lamellipodia.

J. Noh, T. Isogai, J. Chi, C. Burckhardt, G. Danuser; University of Texas Southwestern Med Ct, Dallas, TX.

Crawling cells assemble and disassemble filamentous actin mesh at the leading edge within as short as a minute in order to generate protrusive forces. This process is regulated by numerous actin modulators with substantial functional overlap and entanglement. Understanding the relations between these regulators has been challenging. Conventional molecular perturbation tends to fail as the redundancy between regulators results in immediate compensation. Moreover, the process is highly dynamic and localized in space, which results in an apparent heterogeneity of regulatory states. Here we propose a statistical causal inference framework that builds on established computer vision for morphodynamic profiling to determine directed cause-effect relations between the activities of actin modulators. Our method is based on the notion that signals of causative activity possess indispensable information in explaining the signals of an effector activity, and it extends this concept of Granger-causality inference to the massive spatially and temporally resolved data that can be acquired from live cell imaging. The framework automatically generates Granger-causality network diagrams between edge motion and observed modulator activity. Application of this mathematical framework to the combinatorial imaging of actin, Arp2/3 and VASP demonstrates, as expected, that actin assembly causes edge motion only in a narrow zone from the cell edge in U2OS osteosarcoma cells. Interestingly, actin assembly out of this narrow zone, while positively correlating with edge motion, does not have causal effect. This shows that our inference properly distinguishes causation from correlation. We then find that Arp2/3 recruitment has a strong causal effect on edge motion, mediated by actin assembly. This causal chain applies only within the same narrow zone from the edge, whereas causal links from Arp2/3 to actin more distant to the cell edge have no effect on edge motion. We also find a flow of feedback relations from actin to

Arp2/3, confirming the long-standing notion that a dendritic network architecture yields a mechanism for self-supporting, exponential growth. Applying this approach to VASP and Arp2/3 imaging, the causal network diagram reveals that these two actin regulators have Granger-causal effects on edge motion, yet operate independently. These are the first examples of a novel approach to probing the functional relations in molecular systems with strongly redundant components. We are now prepared to apply this framework to get deeper insight of the mechanisms of actin regulation in lamellipodia and to other systems of similar complexity.

P43/B44

Targeted and Selective Degradation of Mitotic Kinase AURKA by a New PROTAC Tool.

R. Wang[1], K. Roberts[2], **C. Lindon**[1]; [1]University of Cambridge, CAMBRIDGE, UNITED KINGDOM, [2]AstraZeneca, CAMBRIDGE, UNITED KINGDOM.

Targeted protein degradation tools are becoming a new therapeutic modality, allowing small molecule ligands to be reformulated as bifunctional molecules (so-called 'PROTACs') that recruit a ubiquitin ligase to the target of interest, leading to ubiquitination of the target and its destruction via the ubiquitin-proteasome system. This new paradigm of 'event-driven' rather than occupancy-based pharmacology holds great hope for the development of catalytic drugs able to work at lower doses and with higher specificity than the ligands from which they are derived, and with improved pharmacodynamics. Here we describe the functional characterization of a small molecule PROTAC derived from AURKA inhibitor MLN8237 (Alisertib). We describe the efficient and remarkably specific destruction of both endogenous and overexpressed AURKA elicited by PROTAC treatment, and explore the phenotypic consequences of these events.

Automated Passaging, Feeding and Plating on Glass of Gene-edited Human Inducible Pluripotent Stem Cvells for High-throughput 3d Live Cell Microscopy Pipeline.

N. Gaudreault; Allen Institute for Cell Science, Seattle, WA.

The Allen Institute for Cell Science combines genomics, gene editing, and 3D live cell imaging of cell organization to identify and define the various normal and pathological states in which stem cells reside and to unlock the mechanisms by which cells transition among these states. We do this using a collection of human induced pluripotent stem cell (hiPSC) lines expressing green fluorescent protein tags on proteins identifying specific cellular organelles and structures (**the Allen Cell Collection at allencell.org**). To produce large numbers of standardized images, we developed an automated hiPSC culture procedure. We use the Hamilton Robotics Microlab Star platform to generate imaging plates with uniform and reproducible cellular confluency and morphology. Here we provide specific parameters, such as the movements of the plates across the deck, the angle and speed of the aspiration and dispensing of media, the seeding strategies and the timing of every step that we optimized. This approach was developed and applied to coating, seeding, passaging and feeding procedures for cell expansion in 6-well plastic plates, and 96-well glass bottom imaging plates. The overall optimization procedure aimed to preserve the undifferentiated state, maintain pluripotency, and prevent karyotyping abnormality of our gene-edited hiPSC lines for up to 10 passages. We present a side by side comparison of quality control results obtained from manual and automated operations. We also developed an automated image-based colony segmentation pipeline to measure and track colony growth

characteristics over time. The colony feature measurements (number, size, textures, etc.) are used to rank 96-well plates and ensure consistent and adequate quality control. We have also implemented cell passaging based on image-based confluency calculations to eliminate the need for manual cell counting steps. In addition to providing higher uniformity, reproducibility, and overall cell quality for imaging samples, the standardized automation protocol ensures consistency by removing operator to operator variability and potential error or bias introduced by manual repetitive tasks and fatigue of the operators.

Optogenetic Activation of Intracellular Antibodies for Direct Modulation of Endogenous Proteins.

D. Yu; KAIST, Daejeon, KOREA, REPUBLIC OF.

Intracellular antibodies, such as nanobodies and single-chain variable fragments (scFv), have become powerful tools for imaging, modulating, and neutralizing endogenous target proteins. Although a variety of antibody engineering techniques have been developed, an optogenetic tool for activating intracellular antibody to precisely control its target protein has not been reported. Here, we describe an optogenetically activatable intracellular antibody (Optobody) consisting of split antibody fragments and blue light-mediated heterodimerization domains. Blue light stimulation activates the optobody, inducing it to capture its target protein and subsequently inhibit the target. We expanded this optobody platform by generating various optobodies from previously developed intracellular antibodies, and demonstrated that photoactivation of a gelsolin (GSN) optobody and β2 adrenergic receptor (β2AR) optobody shut down endogenous GSN activity and β2AR signaling, respectively. Applying our novel optogenetic platform to the broad pool of available intracellular antibodies will facilitate optogenetic manipulation of various endogenous proteins and may provide a basis for designing potential inducible drugs.

P46/B47

Measuring T Cell Avidity and Enrichment Using Acoustic Force-based Technology.

L. An derson[1], A. Candelli[2], W. Peutz[2], T. Schumacher[3], W. Scheper[3]; [1]Lumicks, Cambridge, MA, [2]Lumicks, Amsterdam, NETHERLANDS, [3]Netherlands Cancer Institute, Amsterdam, NETHERLANDS.

The key driver for effective immune cell therapies is the overall binding strength of the immune cell and the target cell (e.g. tumor cells). The overall strength is known as ‘avidity’, a parameter reflecting interaction efficiency. The key to success for immune cell therapies is generating effective and long-lasting immune responses. The avidity of an immune cell to its target is predicative of its functional potency, but current techniques to measure avidity are low-throughput and ineffective. Herein, we describe the use of acoustic forces to discriminate immune cells based on their avidity to tumor cells. The force required to separate a cell from its target is called the ‘rupture force’, and in this study, we were able to identify the rupture forces of tumor-specific and non-specific T cells and enrich these different populations for downstream characterization. T cells from a healthy donor were transduced with either a non-relevant or a melanoma recognizing T cell receptor and selected with puromycin. Melanoma cells were seeded in the flow cell and allowed to adhere overnight to form a monolayer. For confocal experiments, CFSE and Cell Trace far red stained T cells were mixed in a 1:1 ratio before co-culturing them in the flow cell. T cells engineered with a melanoma antigen-recognizing T-cell receptor needed 6 times more force than non-specific T cells to be separated from the melanoma target cells. Furthermore, 1.4 to 3.6-fold enrichment of high-avidity T cells was obtained from a mixed population of specific and non-specific T cells using acoustic forces. These findings indicate that melanoma-specific T

cells bind with a higher avidity than non-specific T cells and that they can be separated with this approach. In conclusion, we demonstrate a novel method to measure cell avidity and sort cells by utilizing acoustic forces. In addition, this technology is applicable to other research fields. The avidity of different CAR T cell clones to their respective target cells has been measured, serving as an in vitro predictor of CAR T cell functional potency.

OpenCell: Systematic Profiling of Intracellular Organization in Space and Time.

P. Raghavan*[1], L. M. Savy*[1], N. H. Cho[1], Y. J. Li[1], A. D. Brunner[2], K. C. Cheveralls[1], A. C. Michaelis[2], D. N. Itzhak[1], M. Y. Hein[3], J. S. Weissman[3], B. Huang[4], M. Mann[2], M. D. Leonetti[1]; [1]Chan Zuckerberg Biohub, San Francisco, CA, [2]Max Planck Institute of Biochemistry, Martinsried, GERMANY, [3]Dept of Cellular and Molecular Pharmacology & HHMI, University of California, San Francisco, San Francisco, CA, [4]Dept of Pharmaceutical Chemistry, University of California, San Francisco, San Francisco, CA.

*both authors contributed equally to this work

Uncovering the principles driving intracellular organization requires a multi-disciplinary description of the internal architecture of cells. Where are all proteins in a cell localized? Can we map the full network of protein-protein interactions? How can we capture dynamic changes occurring - for example during cell division or differentiation? To address these questions, scalable methods are needed to quantitatively and systematically measure cellular organization in space and time. Here, we present the latest generation of tools we have developed for this undertaking. First, by using the split mNeonGreen system in human embryonic kidney cells, we have expanded robust CRISPR-based methods for the rapid generation of over 1,000 endogenously tagged fluorescent human cell lines. This includes automating the design and analysis of CRISPR editing experiments. Second, we have established optimized protocols for the high-throughput generation of live-cell 3D imaging and interaction proteomics data. Finally, we have implemented open-source automation solutions to streamline tissue culture and clonal selection. These innovations form the basis of OpenCell, our collection of live-cell fluorescence imaging and proteomics data for the genome-wide description of protein function and cellular architecture.

Dynamics and Functions of Antifreeze Proteins in Transgenic *Caenorhabditis Elegans* at Freezing Environments.

M. Kuramochi[1], G. Tou[1], C. Takanashi[1], A. Yamauchi[2], M. Doi[3], K. Mio[4], S. Tsuda[5], H. Sekiguchi[6], Y. C. Sasaki[1]; [1]University of Tokyo, Chiba, JAPAN, [2]Hokkaido University, Hokkaido, JAPAN, [3]AIST, Ibaraki, JAPAN, [4]AIST-UTokyo OPERANDO-OIL, Chiba, JAPAN, [5]AIST, Hokkaido, JAPAN, [6]SPring-8/JASRI, Hyogo, JAPAN.

Antifreeze proteins (AFPs) bind to water molecules organized in ice crystals and modify their shape. The crystal structures of several AFPs have been determined by X-ray crystallography analyses, and the surface complementarity between AFP and water on an ice plane have been evaluated by many structural docking studies. However, less is known regarding whether the ice-binding ability of AFPs actually work in *vivo*, and improve the freezing tolerance in living organisms. To demonstrate this, we generated a transgenic lineage of the nematode *Caenorhabditis elegans* that expresses AFP, and first observed the survival rate of *C. elegans* after freezing exposure. Interestingly, the wild-type AFP improved the survival rate of AFP-expressing *C. elegans* at freezing temperatures (-5°C), whereas the

AFP mutant exhibiting low ice-binding ability did not improve the survival rate at -5°C exposure. These results indicate that ice-binding property is a key factor responsible for freezing tolerance in *C. elegans*. We further observed the AFP dynamical motion in *vivo* for the ice-binding ability by X-ray single molecular observation. Diffracted X-ray Blinking (DXB) evaluates the single molecular motion using the time-resolved X-ray diffraction images from gold-nano crystals. Gold-nano crystals as motion probe were attached AFP of the intestinal cells in *C. elegans*. The motion of wild-type AFP in *vivo* gradually decreased, whereas that of the AFP mutant transiently increased, when the temperature was decreased under 0°C. These results reasonably agree with simulation of AFP molecular dynamics, suggesting that it is important to bind stably AFP to ice-crystals for the tolerance in the living animal. Furthermore, X-ray diffraction from ice crystals were observed during -20°C exposure, and showed its motion dependent on AFP motion.

Towards "Autonomous" Microscopy: Artificial Intelligence Microscopy Screening (aims).

G. Kanfer[1], Y. Maman[2], S. Sarraf[1], H. Baldwin[1], J. Lippincott-Schwartz[3], R. Youle[1]; [1]Biochemistry Section, Surgical Neurology Branch, National Institute of Neurological Disorders and Stroke, NIH, Bethesda, MD, [2]Laboratory of Genome Integrity, National Cancer Institute, NIH, Bethesda, MD, [3]Janelia Research Campus, Howard Hughes Medical Institute, Ashburn, VA.

In cell biology, the identification of new pathways via genetic screens has been a central discovery strategy. Historically, this work was performed most readily in bacteria and yeast; however, it is important to advance this platform in mammalian cells. RNAi-based screens have been used to elucidate pathways in human cells. This approach has relied on two major strategies: arrayed screens, which have high specificity but require the production of each RNAi separately creating a technical bottleneck, and pooled screens, in which production is easier, but specificity and reproducibility suffer. To overcome these limitations, we have developed a novel screening approach termed **A**rtificial-**I**ntelligence **M**icroscopy **S**creening (designated AIMS). The new platform "converts" single cells into "separate" wells by applying machine learning and deep learning algorithms to detect subcellular phenotypes. In brief, a genome-wide suppressor screen is performed on cells expressing dCas9 (CRISPR inhibition) by infecting a single well of cells with pooled guide-RNA (gRNA)-expressing lentivirus so that every cell will express a distinct gRNA. These cells also stably-express a photo-activatable red fluorescent protein (pa-mCherry). Before the screen, a deep learning neural network model is trained on several examples of the phenotype to be queried. Pooled gRNA-infected cells are screened by microscopy and individual cells exhibiting the phenotype that was screened are identified, photoactivated, and isolated via flow cytometry. To identify phenotype to genotype connections, the gRNA lentiviral integration site is sequenced in single cells from the selected sorted cells. We explored the regulation of the transcription factor TFEB. In response to the cellular metabolic state, TFEB initiates lysosomal and autophagy transcriptional programs. Using AIMS, we screened for factors involved in TFEB translocation in or out of the nucleus. In addition to several known hits, novel TFEB regulators were also detected. These results demonstrate the feasibility of AIMS. Our approach is not only a novel implementation demonstrating how machine learning can be used to to explore cell biology, but, this new platform also enables phenotypic-based screening at the subcellular level, an approach which has been largely unavailable.

Designer Membraneless Organelles Equip Eukaryotic Cells with a Second Genetic Code to Enable Orthogonal Translation of Selected Messenger RNAs.

C. D. Reinkemeier, G. Estrada Girona, E. A. Lemke; EMBL, Heidelberg, GERMANY.

Genetic code expansion (GCE) is a powerful tool to study and control protein function with single-residue precision in a variety of organisms ranging from *E. coli* to mice. It is widely used to perform labeling for super-resolution microscopy, photocontrol cellular function, or to introduce site-specific posttranslational modifications. This is achieved by introducing an orthogonal tRNA/synthetase suppressor pair into the living host, to recode a stop codon to incorporate a noncanonical amino acid (ncAA) into the nascent chain. This technique is codon-specific, but it cannot select specific mRNAs, so other naturally occurring stop codons could be suppressed leading to potential interference with housekeeping translation. Nature avoids unwanted cross-talk between cellular processes by confining specific functions into organelles. We aimed to design an organelle dedicated to protein engineering. Inspired by the concept of phase separation we hypothesized that such an organelle could be designed membraneless. Phase separation can generate high local concentrations of proteins and RNAs in cells and has recently gained attention owing to its role in the formation of specialized organelles such as nucleoli or stress granules that perform complex and specific functions inside the cell. We combined phase separating proteins (FUS/EWSR1 or SPD-5) with microtubule motor proteins (KIF13A or KIF16B) to generate orthogonally translating organelles in living cells that contain an RNA-targeting system, the stop codon suppression machinery and ribosomes. These large organelles enable site- and mRNA-specific ncAA incorporation, decoding one specific codon exclusively in the mRNA of choice. Our results demonstrate a simple yet effective approach to the generation of artificial organelles in eukaryotic cells. These semi-synthetic cells are capable of simultaneously executing two genetic codes, one canonical one for untargeted proteins in the cytoplasm and one expanded genetic code for chosen mRNAs inside of the synthetic organelles, thereby providing a route towards customized orthogonal translation and protein engineering.

P51/B52

A Novel Human Uterine Leiomyoma Model for Studying Mechanisms of Fibrosis Induced by Environmental Estrogens.

J. Liu[1], L. Castro[1], N. P. Clayton[1], P. Bushel[1], S. Li[1,2], L. Yu[1], N. D. Flagler[1], E. Scappini[1], Y. Yan[1], D. Dixon[1]; [1]NIEHS, RTP, NC, [2]Johns Hopkins University, Baltimore, MD.

Background: Uterine leiomyomas (fibroids) are highly prevalent benign tumors in women of reproductive age, which often become progressively fibrotic with excessive accumulation of extracellular matrix (ECM) components. Fibroids are estrogen-responsive and may be the target of environmental estrogens. Bisphenol a (BPA) and its analogues (BPS, BPAF) are ubiquitous environmental estrogens, which have been shown to promote fibrosis in rats and mice. The role of environmental estrogens in fibrotic changes in human uterine fibroids is unclear. A deeper understanding of the mechanisms of fibrosis in fibroids requires model systems that closely mimic the in *vivo* tumors. As a result, a 3D human fibroid culture system is being explored as a possibly more realistic system to study the effects of environmental estrogens on fibrosis development. **Objectives:** to develop a human uterine leiomyoma (ht-UtLM) 3D cell culture system to evaluate the role of environmental estrogens (BPA, BPS, and BPAF) on the induction and molecular mechanisms of fibrosis. **Methods:** Ht-UtLM 3D cell cultures

(spheroids) were developed and assessed for viability and microscopic characteristics. Cell proliferation in the 3D model was tested using cell counting kit-8 assays after treatment with BPA, BPS, or BPAF (10^{-6} - 200 μM) for 24, 48 and 72 hours. Differential gene expression was determined at 24 hours using RT² Profiler™ PCR arrays of ECM and fibrosis genes. Fibrosis was evaluated by a Masson's Trichrome stain and western blotting targeting ECM components at 7 days. Network and pathway analyses were done using Ingenuity Pathway an alysis (IPA), and activation of an identified pathway was confirmed by western blotting. **Results:** the 3D ht-UtLM spheroids had a cell viability percentage of 89.77%. BPA, BPS, and BPAF all increased cell proliferation and gene expression including subtypes of collagen genes (COL1A1, COL15A1, and COL16A1), and regulators of fibrosis (TGFB, TGFBR, and SMAD). Compared to controls, fibrosis was more evident in spheroids treated with BPA, BPS, and BPAF at 7 days. ECM components including collagen, fibronectin and versican were increased with all three treatments. BPA, BPS, and BPAF all upregulated expression of profibrotic genes, predicting the activation of the TGF-beta pathway in these profibrotic effects. Phosphorylation of TGFBR1 was increased significantly after treatment with BPA, BPS or BPAF for 3 hours, confirming the activation and involvement of the TGF-beta pathway. **Conclusions**: the 3D fibroid spheroid culture system is an effective and valuable model for studying fibrosis in human uterine fibroids. BPA and its analogues, BPS and BPAF, can promote fibrosis in uterine fibroids through TGF-beta signaling, and may pose as a health risk to women with uterine fibroids.

P52/B53

Building an Image an alysis Pipeline to Measure the Effect of TNF-α on HSV-1 Infected Cells.

M. Ermoshkin[1], E. Maltz[2], A. Oyler-Yaniv[2], J. Oyler-Yaniv[2], R. Wollman[2]; [1]University of Richmond, Richmond, VA, [2]University of California Los an geles, Los an geles, CA.

Computer vision is a set of tools for extracting quantitative information from images in a systematic, reproducible, and unbiased manner. In the context of biological imaging, a typical image analysis pipeline often consists of binary masking, single-cell segmentation, feature extraction, and tracking over time. Here, we construct such a pipeline in Python and apply it to a dataset of HSV-1 (Herpes Simplex Virus-1) infected NIH3T3 fibroblasts treated with TNF-α (Tumor Necrosis Factor). The experimental setup included wells with HSV-1 either present or absent and treated with different TNF-α concentrations. The time-lapse experiment was carried out to investigate the role of TNF-α in inducing apoptosis in HSV-1 infected cells. The pipeline was used to identify all the cells in the microscope images taken for a particular experimental condition. It was then used to track the quantitative properties of identified cells throughout the course of the time-lapse experiment. We find that the image analysis pipeline performs well with over 70% of cells in each frame being successfully tracked. The processed data shows that higher TNF-α concentrations dramatically increase the rate of death in HSV-1 infected cells. This data will then be used to fit a death-proliferation model that predicts if infected cells will undergo apoptosis based on TNF-α concentration and infection with HSV-1.

P53/B54

Pomegranate: a Volumetric Segmentation and Reconstruction Pipeline for Fission Yeast.

E. Baybay, E. Esposito, S. Hauf; Virginia Tech, Blacksburg, VA.

Fission yeast (*Schizosaccharomyces pombe*) is an excellent model organism to study basic eukaryotic cell biology. A feature of fission yeast is its well understood rod-shaped geometry, where cells grow via tip

elongation as they progress through the cell cycle. This feature can be leveraged for the accurate detection and segmentation of cells, as well as for calculating accurate approximations for cell volume. Automated microscopy and image analysis tools have been developed over the past decade with a variety of approaches to cell detection, segmentation, and data collection for fluorescence microscopy images. We have developed a segmentation pipeline, Pomegranate, that uses a combination of bright-field images, fluorescent markers, and the known morphological characteristics of fission yeast to produce a volumetric fit of a cell's whole cell and nuclear geometry. A volumetric fit allows for the analysis of individual regions in a three-dimensional reconstruction of the sample, providing information on the concentration and localization of a protein of interest. In conclusion, Pomegranate proves to be a useful extension to existing image analysis tools for fission yeast, offering a semi-automatic single cell analysis workflow optimized for high density images.

P54/B55

Fast and Predictive 3d Neuron Reconstruction for Light Microscopy Images.

B. Graff[1], H. Sasaki[1], S. McElroy[1], Y. Yi[2], C. Chou Huang[1], H. Zhao[2], S. J. Lee[1], **L. A. G. Lucas**[1]; [1]DRVision Technologies LLC, Bellevue, WA, [2]Texas a & M University, Dallas, TX.

The human brain is composed of approximately 100 billion neurons that collaborate to interpret our senses and control our thoughts and actions. Neuron type, localization and connectivity all contribute to the complex processes required for every organism with a nervous system to function. Thus, systematically reconstructing the 3D morphology of neurons is essential to further advance our understanding of how the brain functions. In the last five years, the BigNeuron project (1) has ran several comparative tests using 30 distinct algorithms for automated 3D neuron reconstruction. The tests were primarily ran using small data sets containing a single neuron or a few sparsely distributed neurons. While these tests were useful at showcasing the pros and cons of each algorithm, many real-world challenges remain when attempting to reconstruct neurons in large and densely populated data sets. We have developed an enhanced voxel scooping algorithm and deployed it in four distinct modes: 1) fully automatic with soma detection, 2) fully automatic without soma detection, 3) semi-automatic path prediction and 4) semi-automatic point-to-point. The last two modes can be used in parallel. To further facilitate the creation of neurons using the semi-automatic modes we have created a dynamic camera mode which follows new traces as they are validated, and we have added an auto-clipping mode which gives users the option to render the data in the region the user is working on. We validated our novel approach on a large data set (1200x1200x2613) depicting a mouse brain section which had been optically cleared using PEGASOS (2) and imaged with a Leica SP8 confocal microscope or the Cleared Tissue LightSheet (CTLS) system (3). Initial tests show that the fully automated version takes 48 mins to complete producing 395 neurons, 815 dendrites, and 325,541 microns in total path length. Thus, the automatic approach can trace approximately 400 mm per hour. The same data set would take an estimated 12 workdays (assuming each day a human expert would manually trace neurons for an average of 5 hours). The estimation is based on 5 hours of human manual tracing which resulted in 33 completed neurons (24,156 microns in total path length), representing a throughput of 4.8 mm per hour. In comparison, when using the semi-automated modes mentioned above, we could trace at a pace of 46 mm per hour. We demonstrated that the automated method was 8.7x faster than the semi-automated method. Moreover, the automated and semi-automated modes are 83x and 9.5x faster in comparison to manual tracing, respectively. We are now testing this approach on even bigger and denser optically cleared data sets imaged with the CTLS.

Quantitative Workflow for Segmentation and Tracking of Large Numbers of Human Induced Pluripotent Stem Cells from Transmitted Light Microscopy Images.

M. Halter, M. Majurski, C. Ling, J. Chalfoun, J. Stinson, A. Plant; NIST, Gaithersburg, MD.

Label-free single cell segmentation and tracking of human induced pluripotent stem cells (hiPSC) from widefield (2D) transmitted light microscopy images could allow for monitoring dynamic cellular processes such as the growth and division of single cells under minimal light exposure conditions. However, segmentation and tracking of cells in such images is challenging because iPSCs are densely packed and distinguishing cell edges in the resulting images is difficult. Classical segmentation techniques failed to meet the required single cell segmentation accuracy on phase contrast or brightfield image modalities. Instead, we used convolutional neural networks (CNNs) with the U-Net architecture to segment single cells within the colonies. Training sets for the U-Net model were generated using the nuclear envelope fluorescence of the LaminB-GFP iPSC line (LMNB1) from the Allen Cell Collection. Classical image analysis algorithms accurately segmented the high contrast, fluorescent images, allowing for abundant availability of training data. We compared the accuracy of two U-Net models: one trained on phase contrast images and the nuclear mask generated by FogBank segmentation and the other trained on brightfield images and the same nuclear mask. Segmentation was most accurate when the network was trained on the phase contrast image modality. The image analysis pipeline consists of segmentation followed by a tracking algorithm (e.g. NIST Lineage Mapper) that identifies mitosis and recognizes merger events when two nuclei cannot be segmented. Importantly, all the reference data for developing and testing the pipeline was acquired with automated equipment and scalable methods, thus facilitating the collection of CNN training data when new segmentation models are required. The application of the workflow for quantifying single cell gene expression dynamics in gene edited iPSCs will be described.

Deep Learning Minimizes the Impact of Fundamental Microscopy Limitations.

H. Sasaki[1], J. Chen[2], H. Lai[1], Y. Yi[3], Y. Su[4], C. Chou Huang[1], S. J. Lee[1], H. Zhao[3], H. Shroff[4], **L. A. G. Lucas**[1]; [1]DRVision Technologies LLC, Bellevue, WA, [2]Advanced Imaging and Microscopy Resource, National Institutes of Health, Bethesda, MD, [3]Texas a & M University, Dallas, TX, [4]National Institute of Biomedical Imaging and Bioengineering, NIH, Bethesda, MD.

Fluorescence microscopy has contributed to numerous major discoveries in life sciences. This is despite the limitations all imaging systems have. Typically, light microscopes excel at just one of the three core factors that modulate image quality and/or sample viability: spatial resolution, temporal resolution and light exposure. To minimize the impact of the mentioned handicaps, deep learning (DL) enabled microscopy image restoration is starting to be adopted (Content Aware Image Restoration (CARE)(1) and our own work (2)). Here we illustrate how a customized Residual Channel Attention Network (RCAN)(3) can be used for image restoration for data created on either an instant structured illumination microscopy (iSIM) or a point (resonant) scanning confocal microscopy. 3D live cell imaging of mitochondria and lysosomes using iSIM: training was done using 20 3D image pairs depicting cells with Tom20-labelled mitochondria and 20 3D image pairs with Lamp1-labeled lysosomes. All 3D images were 1.9K x 1.5K x 14 voxels. The raw input images (RII) were captured using 3.4 W/cm^2 laser and the ground

truth (GT) data was acquired using 0.37 kW/cm^2 laser. Routine live cell iSIM imaging is done at ~ 100 W/cm2 - which significantly limits the length of recordings. The trained model was applied to 3D+time (500 time points) acquired at low laser power (3.4 W/cm^2) that was not used for training. Applying the trained model to new RII significantly improved signal to noise ratio (SNR), spatial resolution and overall appearance versus the RII. Fast image acquisition of cleared 3D samples using a confocal system in resonant mode: Training images were created with a confocal microscope with a 40x 1.3 NA objective lens and resonant scanner in single-line mode (RII) or 64-line average mode (GT). Acquiring GT data took >3x longer than acquiring the equivalent raw images. The RII had low SNR and included major pixel shift artifacts, normal for resonant scanning. The GT had high SNR and no noticeable artifacts. Training was done using 8 3D image pairs depicting fluorescently labelled neurons. Applying the trained DL model to new RII resulted in high SNR and spatial resolution images. We demonstrate that DL can greatly diminish the amount of light the sample is exposed to, allowing for a dramatic extension in experiment duration while retaining the capability to perform super resolution imaging. We demonstrate this capability by studying the dynamic interaction of mitochondria and lysosomal vesicles using iSIM. In addition, we discuss how the same type of approach can be adopted to significantly reduce the time needed to image optically cleared brain samples when using a point scanning confocal system equipped with a resonant scanner, while maintaining the spatial resolution.

GPU-accelerated Machine Learning-powered 3d Image Segmentation at Scale.

M. Jones, C. McBride, T. Lancon, Q. Tran, H. Lai, S. McElroy, S. J. Lee, **L. A. G. Lucas**; DRVision Technologies LLC, Bellevue, WA.

Despite the recent advances in bio-imaging, the extraction of meaningful insights from large multi-dimensional microscopy images continues to be a major bottleneck to the advancement of science. Non-machine learning tools use manually engineered algorithms to generate results. They are inflexible and require a user to master several user-facing parameters before one can efficiently use the tools. By contrast, machine learning (ML) based solutions, only require the user to draw a few regions representing the object types of interest, are starting to be adopted by researchers as they are much easier to master. However, ML based image processing approaches suffer from a different drawback, they are computationally expensive and thus benefit from processing optimizations so that they can be used at scale. Here we discuss enhancements made to our ML-based image segmentation solution, Aivia's Pixel Classifier. We have implemented a wide range of 3D filters optimized for 3D data. Moreover, we have implemented a new train and apply pipeline which uses GPU, instead of CPU processing. The new GPU-accelerated ML-based image segmentation approach was compared to our previous state of the art ML-based image segmentation framework presented at this conference in 2018[1]. We used a test image with the following (xyz) dimensions: 607x531x61, 32 bit. Computer environment used: Windows 10, 16 GB RAM, NVIDIA GeForce GTX 1060 GPU, i7-6700HQ CPU @ 2.6 GHz. In two class segmentation, the GPU accelerated solution achieves 13 times speed up (55 seconds vs. 4 seconds). Moreover, RAM usage was reduced by 35x (7 GB vs. 0.2 GB). Next, we will benchmark the new approach using multiple image sizes as well as >2 segmentation classes. In conclusion, we found that the new solution was ~13x faster while requiring 35x less memory (RAM). This will allow researchers to benefit from the ease of use of ML-based image segmentation approaches while being able to process large data sets and/or multiple data sets.

New Techniques in Genomics and Proteomics: CRISPR

Crispr-cas9 Engineered Isogenic Luciferase Expressing Cell Lines as in *Vitro* and in *Vivo* Models for Cancer Research.

J. Foulke, L. Chen, E. Turner, **F. Tian, 20877**; ATCC, Gaithersburg, MD.

The CRISPR-Cas9 system provides a robust gene-editing tool for basic research in biology and for the development of diseases models for translational research. The objective of this study is to use advanced technologies including CRISPR-Cas9 and bioluminescence to generate novel human cell lines for use as both in *vitro* and in *vivo* models in cancer research. Approximately 50% of melanoma patients have the $BRAF^{V600E}$ mutation and often become resistant to current BRAF inhibitors after several months of treatment. $KRAS^{G13D}$ is an acquired mutation associated with resistance to these inhibitors. In this study, CRISPR-Cas9 was used to knock-in the $KRAS^{G13D}$ point mutation into the A375 malignant melanoma cell line, which also contains the targetable $BRAF^{V600E}$ mutation. The resulting $KRAS^{G13D}$ mutant isogenic line A375, which has been validated at the genomic, transcript, and protein bio-functional levels, exhibits significant resistance to the BRAF inhibitors Dabrafenib and Vemurafenib when studied both in traditional 2D and 3D cell culture. Based on the in *vitro* model described above, we developed additional models for use in live-animal bioluminescence imaging by introducing a stable luciferase reporter into the isogenic A375 and $KRAS^{G13D}$ A375 cell lines. Both the relative and absolute bioluminescence signals within the cells were quantified and found to emit $4.9x10^5$ photons/cell/sec and $3.5x10^5$ photons/cell/sec, respectively. A subcutaneous xenograft model was utilized in this study and the in *vivo* live bioluminescence signal was quantified using the Xenogen IVIS imaging system to correlate tumor growth with luciferase expression. Both A375-Luc2 and $KRAS^{G13D}$ A375-Luc2 grew as subcutaneous tumors with increasing levels of bioluminescence when injected into nude mice. In addition, a portfolio of 5 human isogenic luciferase reporter cell line pairs and 18 human and mouse luciferase reporter cell lines were developed for the study of various cancer types. In conclusion, the combination of two technologies CRISPR-Cas9 technology and stable luciferase expression allows for the generation of isogenic luciferase expressing cell lines, which are valuable tools for elucidating mechanisms involved in tumorigenesis and for studying drug responses in *vitro* and in *vivo*.

P59/B60

Tissue-Specific Knockout of Genes in Mice Using DECAI CRISPR.

E. McBeath, M. Hofmann; University of Texas MD an derson Cancer Center, Houston, TX.

Although it is easy to produce mice with a point mutation using CRISPR, it is much more difficult to make a mouse with the two loxP sites required for tissue specific knock out. Several specific methods for generating floxed mice by CRISPR have been developed to improve the low efficiency of correct dual loxP insertion but they are either technically challenging (microinjection into two-cell-stage mouse embryos, sequential injection) or do not work much better (long ssDNA donor containing both loxP sites with two guide RNAs) than the standard CRISPR method. A different approach which they called DECAI (DEgradation based on Cre-regulated-Artificial Intron) was recently taken by Bürckstümmer's group. Using human stem cell lines, they inserted a small artificial intron via CRIPSR into an exon found in all

isoforms of the protein they were trying to knock out. This intron has loxP sites on each side of its branch point and without Cre, splices itself out of the mRNA, leading to normal protein production. The intron also has 3 STOP codons in different frames so when the branch point sequence is removed by Cre, one of the STOP codons is put in-frame, in turn leading to degradation of the mRNA and knocking out protein production. As we are interested in how the protein BHC80 encoded by the gene *Phf21a* is involved in the epigenetic control of spermatogenesis, we decided to try this method in mice to ultimately knock out *Phf21a* in the presence of Cre in Sertoli cells. Using a system we developed earlier that quickly and closely predicts the mutational outcome of CRISPR treatment in mice using blastocysts, we tested how efficiently the artificial DECAI intron would be inserted by CRISPR. In this procedure, DNA is PCRed from mouse blastocysts previously injected as zygotes with the same CRISPR components intended to produce the engineered mice, then Sanger sequenced. Initial results are very promising, with over 35% of the blastocysts showing evidence of perfect insertion of the artificial DECAI intron and therefore a floxed *Phf21a* gene.

P60/B61

Development of an Imaging Based Pooled CRISPR Screening Platform.

X. Yan; UCSF, san francisco, CA.

Recent development of CRISPR based screening technology provides new ways to quickly examine gene behavior on a genome wide scale. However, such screens generally require the application of a selection pressure to the entire cell population to identify a specific phenotype, mostly an extreme life and death phenotype. These requirements prevent its application to lots of interesting scenarios especially when morphological feature changes which does not lead to immediate cell death. To overcome this disadvantage, we developed a screening platform which preserves the power inherited from pooled format CRISPR screen, but utilizing microscopy detection followed by FACS to isolate specific cell population. To prove its feasibility, we applied this method to screen for regulators of nuclear size and identified 17 potential hits. This approach combines the strength of both pooled format CRISPR technology and imaging technology for easy and accurate phenotype identification, which could be widely applied to different cell biology researches.

P61/B62

An Easy CRISPR Regulator and Editor System.

L. Wu, M. Li, M. Liu, X. Liu, Y. Wang; Origene, Rockville, MD.

CRISPR has been developed as an important tool for DNA and RNA editing. Our all-in-one CRISPR system integrates the gRNA and Cas9 into one vector in order to fix the transfection molar ratio as 1:1. Using this system, we have developed several genome-wide CRISPR kits, such as CRISPR KN (Knockout), CRISPRa (activation) and CRISPRi (inhibition), and also CRISPR v3.0 dimerization system. Our CRISPRa/i are based on dCas9 platform, which can specifically regulate target promoter activities. Individually, our CRISPRa system is a modified SAM system, which displays a highly-efficient stimulating activity, and CRISPRi, built on the backbone of dCas9-KRAB-MeCP2, is able to act as an ideal inhibitor to target genes. Furthermore, our CRISPR v3.0 dimerization system is designed to couple different effectors to dCas9 platform upon the treatment of drug APA. This system could provide inducible gene regulation with lower off-target effects and better background control. In conclusion, our all-in-one CRISPR platform is an effective tool for DNA and RNA editing application.

P62/B63

Multiplex Genome Editing of Human Natural Killer Cell via Optimized CRISPR-Cas9 RNP Transfection.

R. Huang, S. Lin; Academia Sinica, Taipei, TAIWAN.

Natural Killer (NK) cell is an effective arsenal in immune system against malignant cells, and a promising cell type for immunotherapy. Activation of NK cell is an intricate process that involves the interaction between a series of NK cell surface receptors and target cell ligands, providing positive and negative signaling to ultimately determine the activation status of NK cells. A robust and precise genetic tool will be useful to dissect this complex mechanism and to allow engineering of NK cells with enhanced cytotoxicity against malignant cells. Currently, the mainstream genetic engineering of NK cell still relies on viral transduction, which is inefficient due to NK viral resistance and imprecise because of random viral integration. By leveraging the power of nucleofection, we are able to efficiently deliver pre-assembled CRISPR-Cas9:sgRNA ribonucleoprotein complexes (Cas9 RNP) into primary NK cells for multiplex genome editing. Parameters of nucleofection were extensively optimized for maximal Cas9 RNP editing, including buffers, nucleofection programs and dosage of Cas9 RNP. The genetic knockout efficiency of human NK cell is up to 90% while maintaining the viability at 90%. Multi-gene knockout in one-shot nucleofection is also achieved. We further established an expansion procedure for cryopreserved human primary NK cells. The expanded primary NK cell possesses intact NK cell markers and can be engineered by our optimized Cas9 RNP nucleofection protocol. Our results demonstrate the experimental feasibility of human primary NK cell sourced from frozen stock, when PBMCs from fresh blood is not easily accessible. Collectively, our work facilitates biological research and therapeutic engineering of human NK cell for off-the-shelf immunotherapy.

P63/B64

Novel Reagent for Cas9 Ribonucleoprotein Delivery into Stem Cells.

C. Khodthong, N. Rossi, A. Pinchuk, L. Juckem; Mirus Bio LLC, Madison, WI.

The CRISPR/Cas9 genome-editing platform is a versatile and powerful technology to efficiently create genetically engineered living cells and organisms. This system requires a complex of Cas9 endonuclease protein with a gene-targeting guide RNA (gRNA) to introduce double-strand DNA breaks (DSBs) at specific locations in the genome. DSBs are then repaired by either the error-prone Non-Homologous End Joining (NHEJ) or the more precise homology-directed repair (HDR). NHEJ leads to randomly insertions and/or deletions (indels) which disrupt the targeted locus whereas HDR relies on the presence of a donor template for the precise sequence modifications. The success of CRISPR genome editing experiments in stem cells is limited by the intracellular delivery and expression of Cas9 protein and gRNA. Many methods for achieving CRISPR mediated genome editing have been identified and the choice of DNA, RNA or ribonucleoprotein (RNP) format is dictated by experimental goal and cell type. Multiple studies have found that CRISPR/Cas9 components delivered using RNP are associated with lower off-target genome editing when compared to other methods. However, the lack of techniques that can efficiently deliver RNP with low cytotoxicity in stem cells limits the use of RNP for genome editing in these cell types. To overcome this limitation, we performed an RNP delivery optimization and screened a large candidate of cationic polymer and lipid combinations in two human induced pluripotent stem cells (iPSCs) lines. The novel formulations that we identified from the screen offer low toxicity and superior RNP delivery in iPSCs when compared to leading commercially available

transfection reagents. Moreover, this formulation can be used to deliver DNA oligo donors for HDR genome editing. The ability to safely and efficiently deliver RNP into stem cells will enable a wide range of scientific studies from gene expression modulations to drug discovery screening.

P64/B65
Genome Editing Platform Using Engineered Cas9, Which Has the Enhanced Pam Flexibility and Dna Specificity.
L. Min, 20850, M. Liu, Y. Shi, P. Wei, X. Liu, Y. Wang; OriGene Technoligies, Inc, Rockville, MD.

Genome Editing Platform using Engineered Cas9, which has the Enhanced PAM Flexibility and DNA Specificity Li Min, Mingjuan Liu, Yuhong Shi, Ping Wei, Xuan Liu, Yiran Wang CRISPR-Cas9 nucleases have already been widely used for genome editing. Cas9 and other enzymes need a protospacer adjacent motif (PAM) adjacent to the targeted site. The most commonly used SpCas9 needs NGG 3' end of the targeted sequence. NGG occurs frequently in GC-rich genomes, in every 42 bases of human genome. However, gene editing with SpCas9 will be limited for AT-rich regions. To solve this problem, SpCas9 mutants were explored for broader PAM recognition. The engineered Cas9 was reported to have broad PAM recognition and increased specificity. The engineered Cas9 was tested in our CRISPR mammalian genome editing system and demonstrated the Enhanced PAM Flexibility and DNA Specificity.

Nuclear Actin Polymerization Regulates Transcription through Facilitating Rna Pol Ii Phase Separation.
S. Shao, 100871, H. Zhang, Y. Sun; Peking University, Beijing, CHINA.

Transcription controls essential cellular processes including selective genes expression and cell differentiation. A variety of proteins are involved in the regulation of RNA Pol II transcription. Nuclear actin, as one of these regulators, is critical for the transcription of RNA Pol II, but the molecular mechanisms remain unknown. The phase separation regulation mechanism during transcription has been uncovered in the last two years, revealing the important role of phase separation in maintaining chromatin structure and regulating transcription. In this work, we studied the regulation of nuclear actin on RNA Pol II from the perspective of phase separation. Through establishing a live cell imaging system to control the phase separation process of RNA Pol II in real time and a sensitive and interference-free nuclear actin labeling method, we found that nuclear actin is involved in the regulation of transcriptional processes by controlling RNA Pol II phase separation through interacting with multiple proteins, including PSF, Nono, N-WASP, and Arp2/3 complex. Importantly, we also demonstrated that signaling such as serum stimulation caused polymerization of nuclear actin, enhanced the interaction between unstructured regions of RNA Pol II, and promoted RNA Pol II phase separation. Using the new phase separation concept to explain the long-conflicted nuclear actin regulation of transcription has opened up a new perspective for the study of nuclear actin function, increase our understanding of transcriptional regulation, and guide us to understand more phenomena in the cell from the view of phase separation.

The Role of Src Kinase in Regulation of Dynamin-2 Activity at Podosome.

T. Hsieh, s. Lin, Y. Liu; National Taiwan University, Taipei, TAIWAN.

Podosomes are Src kinase regulated and actin-rich structures critical for cell adhesion, migration and invasion. While the membrane remodeling GTPase dynamin-2 has been found to be enriched at podosomes to mediate adhesion molecule endocytosis as well as to regulate the bundling of actin and the stiffness of podosome, the mechanism orchestrating the function and recruitment of dynamin-2 to podosome is still unclear. Given that dynamin-2 is a substrate of Src kinase, we hypothesize that Src kinase phosphorylation on dynamin-2 may play an important role for its activity at podosome. We thus investigate the effect of dynamin-2 mutants on the Src phosphorylation sites with cell biology and biochemistry approaches. We found that both the phospho-mimetic and phospho-deficient mutants of dynamin-2 have significant impacts on dynamin 2-actin association both in C2C12 myoblast and in *vitro*. Furthermore, the Src-mediated phosphorylation also affects the GTP hydrolysis activity of dynamin-2. Together, our findings demonstrate that Src kinase phosphorylation on dynamin-2 regulates its function in podosome.

Deconstructing the Presynaptic Actin Cytoskeleton.

B. Ermanoska, A. A. Rodal; Brandeis University, Waltham, MA.

Actin is the most abundant cytoskeletal protein at presynaptic terminals, where it is heavily implicated in many functions, ranging from vesicle mobilization and traffic to morphogenesis and stability of the synapse. However, little is known about how diverse types of actin assemblies are organized and coordinated at these sites. Here, we aim to characterize components and regulators of actin cytoskeleton (other than actin itself) in presynaptic terminals at the *Drosophila* larval neuromuscular junction (NMJ), a model synapse that offers unique access for studying synaptic biology in the animal. For this purpose, we down-regulated 23 actin-associated proteins (AAPs) in the fly nervous system and examined their effects on actin assemblies, using genetically encoded fluorescent actin and actin-labeling markers. Neuronal down-regulation of AAPs (including actin nucleators, capping proteins, stabilizers, network regulators, cross-linkers, actin-based myosin molecular motors) affected the levels as well as the distribution of F-actin at the synapse. In particular, a prominent synaptic subpopulation of actin patches exhibited complex changes in both number and size upon downregulation of conserved AAPs, molecules associated with the spectrin submembraneous cytoskeleton, as well as myosin motors. In parallel, we studied the effect of the down-regulation of the AAPs on synaptic morphology, and on the active zone and periactive zone at the NMJ. Overall, we identified unique and overlapping molecular players in the organization of different functional components of the synapse. In sum, our results present first in *vivo* screen of presynaptic actin regulators/components and point to potential regulators of different actin assemblies, affecting distinct synaptic structures/functions. For future studies, we aim to obtain more detailed picture on individual AAPs, and their contribution to the stability and function of presynaptic actin assemblies.

Myosin18aα Targets the Rac Gef β-pix to the Dendritic Spines of Cerebellar Purkinje Neurons to Promote Actin-dependent Spine Maturation.

C. J. Alexander[1], M. Barzik[2], R. S. Petralia[2], Y. Wang[2], T. B. Friedman[2], J. A. Hammer[1]; [1]National Heart, Lung, and Blood Institute, NIH, Bethesda, MD, [2]National Institute on Deafness and Other Communication Disorders, NIH, Bethesda, MD.

Dendritic spines are signaling microcompartments that serve as the primary site of synapse formation in neurons, and that house the machinery underlying memory formation. Actin assembly and myosin 2 contractility play critical roles in the maturation of spines from filopodial precursors. Myosin 18A is a myosin 2-like protein expressed from flies to man that lacks motor activity, is sub-stochiometric to myosin 2, and co-assembles with myosin 2 to make mixed filaments (Billington et al., 2015). Myosin 18A is alternatively spliced to create multiple isoforms that contain unique N- and C-terminal extensions harboring both recognizable and uncharacterized protein: protein interaction domains. These observations suggest that myosin 18A serves to recruit proteins to mixed filaments of myosin 2 and myosin 18A. One such protein is the Rac/Cdc42 guanine nucleotide exchange factor (GEF) β-PIX, which is known to promote spine maturation by activating the nucleation promoting factors WAVE and WASp, leading to Arp2/3-dependent branched actin filament assembly (Zhang et al., 2005; Saneyoshi et al., 2008; Yan et al., 2013). Here we show that myosin 18Aα is highly expressed in cerebellar Purkinje neurons and concentrates in spines along with myosin 2 and F-actin. Myosin 18Aα's spine targeting is driven by both co-assembly with myosin 2 and an actin binding site present in its N-terminal extension. miRNA-mediated knockdown of myosin 18Aα results in a significant defect in spine maturation that is manifested as increases in spine length and density, and that is rescued by an RNAi-immune version of myosin 18Aα. Importantly, β-PIX co-localizes with myosin 18Aα in spines (but not when its myosin 18Aα binding site is deleted), and its spine localization is lost upon myosin 18Aα knockdown. Moreover, myosin 18Aα knockdown results in a significant reduction in the amount of F-actin per spine. These and other data argue that mixed filaments of myosin 2 and myosin 18Aα present within Purkinje neuron spines form a complex with β-PIX that promotes the conversion of filopodia precursors into mature spines by activating Arp2/3-dependent branched actin filament assembly downstream of β-PIX's GEF activity.

Simulating the Actin Cytoskeleton during Bleb Nucleation.

C. Pozderac[1], **W. Strychalski**[2]; [1]The Ohio State University, Columbus, OH, [2]Case Western Reserve University, Cleveland, OH.

Blebs are round membrane protrusions that are involved in important cellular processes such as cell motility, cytokinesis, and apoptosis. Recent studies have focused on the importance of cells that use blebs for cell migration in 3D fibrous environments. Blebs are initiated either by a local delamination of the actin cortex from the membrane due to loss of membrane-cortex adhesion proteins or by a local disruption of the actin cortex. In either case, the cortex degrades in the region of bleb initiation and then reassembles in the bleb. Myosin contractility has been shown to be necessary for bleb formation. It has further been hypothesized that a localized increase in myosin contractility on the cortex results in a rupture of the actin network that can lead to bleb nucleation. A minimal model consisting of actin filaments, myosin molecular motors, and actin cross-linker proteins is used to quantify conditions where

holes, or defects, can develop in an initially isotropic cytoskeletal network. The model is simulated using the Cytosim computational platform. Results show that increased myosin fosters actin alignment, while increasing the concentration of actin cross-linkers decreases the pore size of the cytoskeletal network. Holes in the actin network develop at relatively high concentration of both cross-linkers and myosin. Simulation results suggest that a spatially localized defect, representing cortical actin network architecture during bleb nucleation, requires localized actin depolymerization rather than localized distributions of cross-linkers and myosin.

The Drosophila Melanogaster Rab Gap RN-tre Plays a Role in Regulating Non-muscle Myosin Ii Localization and Function.

A. Platenkamp[1], E. Detmar[2], L. Sepulveda[1], A. Ritz[1], S. L. Rogers[2], **D. A. Applewhite**[1]; [1]Reed College, Portland, OR, [2]University of North Carolina, Chapel Hill, NC.

To identify novel regulators of non-muscle myosin II (NM II) we performed a targeted RNAi screen using a stable Drosophila melanogaster S2 cell line expressing EGFP-tagged regulatory light chain (RLC) of NM II and mCherry-Actin. This screen yielded a single hit, the Rab-specific GTPase-activating protein (GAP) RN-tre. Using total internal reflection fluorescence (TIRF) microscopy, we found that RNAi depletion of RN-tre led to a loss of NM II RLC localization in a manner that phenocopied depletion of proteins in the Rho pathway. This loss of localization corresponded to a loss of function as well—depletion of RN-tre led to an increase in actin retrograde flow rates and a decrease in S2R+ cells' ability to constrict in a cellular contractility assay. We next wanted to determine if RN-tre's regulation of NM II is dependent on its GAP activity. Interestingly, over-expression of constitutively active Rabs 5, 6, and 19, all of which are thought to be inactivated by RN-tre, failed to alter NM II RLC localization. Instead, we found that expression of constitutively active Rho, Rho-kinase (Rok), and the phosphomimetic NM II RLC could each rescue the loss of localization following RN-tre depletion. Furthermore, we assayed the cells for phosphorylated RLC by immunostaining and found a substantial decrease in phosphomyosin-positive cells following RN-tre depletion. In addition, depletion of RN-tre led to a decrease in the amount of active Rho as compared to controls. Collectively, our results suggest that RN-tre plays an important regulatory role in NM II RLC distribution, phosphorylation, and function, likely through conserved Rho signaling and is an example of cross-talk between the secretion machinery and actomyosin contractility.

P71/B73

Active Rho G-proteins Are Necessary for the Recovery of Damaged Hair Bundle Mechanoreceptors in *Nematostella Vectensis*.

S. S. Menard-Harvey[1,2], G. M. Watson[2]; [1]University of North Carolina at Charlotte, Charlotte, NC, [2]University of Louisiana at Lafayette, Lafayette, LA.

Hair bundle mechanoreceptors located on the tentacles of sea anemones become disorganized when the animals are immersed in calcium-free seawater. Such disorganization causes loss of function of the hair bundle mechanoreceptors. However, organization returns to the hair bundle mechanoreceptors once the animals are immersed in calcium-containing seawater. As part of the normal recovery of the morphology (and function) of the hair bundles, reorganization of the actin cytoskeleton occurs within the stereocilia of the hair bundles. In previous studies, Rho G-proteins have been localized to the stereocilia of hair bundles and found to be involved in actin polymerization. This study aims to

determine whether active Rho G-proteins are critical during recovery of hair bundles from damage caused by immersion in calcium-free seawater. This study includes the use of Rho inhibitors, phalloidin staining, and various types of microscopy (i.e., phase-contrast, oblique, and fluorescence). Following a 1-hour immersion in calcium-free seawater, there is a significant decrease in the abundance of hair bundles at the tips of tentacles. Over the course of a 6-hour recovery period in calcium-containing seawater, a partial recovery in abundance of hair bundles occurs within 3 hours, but a full recovery does not occur within 6 hours. During the recovery period, hair bundles significantly widen at the tips within 2 hours of recovery before returning to tip widths comparable to untreated controls within 6 hours. Additionally, stereocilia of hair bundles become significantly longer compared to untreated controls within 2 hours of recovery before returning to lengths comparable to untreated controls within 6 hours. Following the addition of Rho inhibitors to the calcium-containing seawater, progress in the recovery of abundance and morphology of hair bundles is hindered. Neither recovery of abundance of hair bundles nor elongation of stereocilia occurs within the 6-hour recovery period in the presence of Rho inhibitors. These data suggest that active Rho G-proteins are necessary for the normal recovery of abundance and morphology of hair bundle mechanoreceptors damaged by immersion in calcium-free seawater.

Cell Cycle and Cytoskeletal Dynamics during *C. Elegans* Muscle Progenitor Migration.

R. C. Adikes[1], O. B. Ahmed[1], B. Goldstein[2], A. M. Pani[3], D. Q. Matus[1]; [1]Stony Brook University, Stony Brook, NY, [2]University of North Carolina at Chapel Hill, Chapel Hill, NY, [3]University of Virginia, Charlottesville, VA.

Defects in cell cycle regulation or morphogenic movements are associated with many pathogenic processes and are regarded as hallmarks of cancer metastasis. Here we explore the migration and differentiation of mesodermal precursor cells in the nematode *C. elegans* as a model for cell cycle and cytoskeletal regulation of a morphogenic movement. The *C. elegans* sex myoblasts (SMs) are derived from progenitors that migrate during larval development and then proliferate and differentiate into the adult vulval muscles. The two SM founder cells travel anteriorly during the second larval stage until they flank the gonad. Upon arrival, the SM cells undergo three rounds of cell division before terminally differentiating into uterine and vulval muscle. Several signaling pathways and guidance cues important for SM specification, migration, and differentiation have been identified by classical methods, but the cell biological mechanisms underlying SM migration and pre-differentiation remain largely unknown. To explore cellular mechanisms, we used high-resolution, time-lapse microscopy to analyze the behaviors of SM cells in *vivo*. We show that these cells generate numerous actin rich filopodia and exhibit complex cytoskeletal dynamics throughout their lifetime. To further investigate the role of cytoskeletal dynamics during SM pre-differentiation we are performing an RNAi screen of candidate genes that we hypothesize may regulate SM migratory and protrusive behaviors. Furthermore, using a newly developed cell cycle state sensor we establish that SMs are in G0 quiescence when they migrate, and re-enter the cell cycle upon arrival. These findings lay the groundwork for establishing *C. elegans* SMs as a cell-biological model for cell migration and protrusion formation in *vivo* to study the relationship between migration, protrusion, cell-cycle state and cytoskeletal regulation.

NRIP Not Only Affects Myogenesis Differentiation but Also Acts as a Novel Actin Binding Protein for Myotube Fusion.

S. Chen; National Taiwan University, Taipei, TAIWAN.

NRIP is a Ca^{2+}-dependent calmodulin-binding protein and responsible for muscle contraction. To investigate NRIP role in muscle development, firstly, we found that NRIP could be expressed in various tissues such as muscles, heart, brain at embryonic stage; and NRIP expression profile in limb muscle tissues started at embryonic stage during muscle development, and peaked at postnatal P1 and P7, and mildly less expression at 6 weeks. To characterize NRIP role in myogenesis, we found that primary myoblasts from muscle specific NRIP knock out mice significantly exhibited the deficit differentiation and myotube fusion, the results also found in NRIP-null C2C12 cells. Fistly, to illustrate NRIP function in myogenesis differentiation, the muscle specific NRIP knock out mice revealed the delayed satellite cells activation/proliferation and differentiation; that further supports NRIP involved in myogenesis differentiation. Intriguingly, we found that NRIP is a novel actin binding protein and located at membrane. In our previous study, NRIP global knockout (gKO) mice show higher frequency of small myofiber size distribution than wild-type mice at day 21 post cardiotoxin-induced injury during muscle regeneration, indicating that NRIP may regulate myoblast fusion to form myofiber. Myoblast fusion has been reported to be strongly associated with actin cytoskeleton remodeled by actin-binding proteins. To examine NRIP role in myotube formation, NRIP was found to locate and accumulate at cell contact site of myoblast-myoblast and myoblast-myotube (containing two nuclei), and NRIP colocalized with actin to form podosome-like structure. By using time-lapse microscopy analysis revealed the dynamic changes of the actin cytoskeletal remodeling between NRIP and actin in C2C12 during myoblast fusion in which at initial (0-30 min) the actin and NRIP-enriched foci in cytoplasm of C2C12, and then (60-180 min) the foci protruded toward cell membrane to form a podosome-like protrusive structure which might participate in invasion during myoblast fusion. Moreover, NRIP was characterized for direct participation of fusion process using cell fusion assay (C2C12-KO19); indicating that NRIP could increase the proportion of fused myotube with more nuclei. Taken together, NRIP not only affects myogenesis differentiation but also acts as a novel actin binding protein for myotube fusion.

P74/B76

Cytoskeletal Tension Regulates Cell Growth and Proliferation.

K. Yao, N. Rochman, N. Perez, S. Flanary, L. Sablich, E. Crentsil, S. Sun; Johns Hopkins University, Baltimore, MD.

Cell mechanical behavior plays crucial roles in growth, proliferation and disease progression. In particular, cytoskeletal tension may modulate intracellular biochemical signaling pathways, and affects cell growth and proliferation through mechanotransduction mechanisms. Here, using Y-27632, a ROCK (Rho-associated protein kinase) pathway inhibitor, we uncover novel relationships between cytoskeletal tension, protein synthesis, cell cycle and cell volume. We show that Y-27632 significantly suppresses phosphorylation of myosin light chain and YAP nuclear translocation. We discover that cell shape changes dramatically and cell volume decreases gradually by 20% in 2 hours upon Y-27632 inhibition in both HT1080 and NuFF cells. Furthermore, we show that protein synthesis rate is down-regulated upon Y-27632 inhibition, with a response time longer than cell volume decrease. In addition, we find that inhibiting myosin assembly and cell tension slows down cell cycle progression from G1 to S. These

results suggest that cell cytoskeletal tension not only acts as a regulator of cell migration and differentiation, but also influences cell cycle, cell growth and proliferation.

P75/B77

Molecular Mechanism for Differential Force-regulated Actin Binding by Vinculin and α-catenin.

L. Mei[1,2], S. E. de los Reyes[1], M. J. Reynolds[1], S. Liu[1], G. M. Alushin[1]; [1]The Rockefeller University, New York, NY, [2]Tri-Institutional PhD Program in Chemical Biology, New York, NY.

Cells in the body must perceive and appropriately respond to mechanical stimuli in their local microenvironments during development and to maintain homeostasis. Dysfunction of mechanical signal transduction (”mechanotransduction”) pathways is correspondingly implicated in a wide variety of human diseases, including metastatic cancer, muscular dystrophy and cardiomyopathy, yet therapeutics targeting these pathways are largely absent due to the lack of knowledge of the underlying molecular mechanisms. The actin cytoskeleton plays a central role in mechanotransduction through the regulated interactions between actin filaments (F-actin) and more than 150 actin-binding proteins (ABPs). Research at the cellular and tissue levels have implicated mechanical regulation of actin-ABP interactions in mechanotransduction, but how force regulates critical actin-ABP interactions at the molecular level is largely unknown. Here we have employed biophysical and structural biology techniques to address this question. Using a novel myosin-motor based TIRF reconstitution assay, we find that a pair of homologous ABPs which are essential for cell-cell and cell-matrix adhesion, α-catenin and vinculin, have distinct mechanosensitive F-actin binding. The actin-binding domain (ABD) of α-catenin preferentially engages F-actin in the presence of mechanical load across actin filaments (“mechanoaccumulation”), while vinculin’s ABD does not. Simultaneous optical trapping and confocal microscopy experiments demonstrate that a load of ~1 pN across single filaments activates α-catenin ABD binding. Atomic resolution cryo-EM structures of the metavinculin ABD-F-actin (2.9 Å) and α-catenin ABD-F-actin (3.2 Å) complexes demonstrate both ABDs undergo major conformational changes upon actin engagement, prominently at their N- and C-termini, and their C-terminal regions differentially refold to bind distinct sites on the filament surface. A C-terminal truncation of α-catenin’s ABD constitutively binds F-actin regardless of force, and a chimeric protein of vinculin’s ABD featuring α-catenin’s flexible termini gains mechanoaccumulation activity, suggesting the α-catenin C-terminus-F-actin interaction is necessary and sufficient for mechanically regulated binding. This work, for the first time, establishes a force-regulated actin-binding mechanism in structural detail, and lays the groundwork for the rational design of therapeutics targeting cytoskeletal mechanotransduction pathways.

P76/B78

Modular Lim Domains Are Direct Sensors of Actin Strain to Mediate Mechanotransduction.

X. Sun[1], D. Phua[1], L. Axiotakis, Jr.[2], M. Smith[3], A. Pasapera[2], R. Gong[1], R. Cail[2], S. Espinosa[1], C. Waterman[2], M. Beckerle[3], G. Alushin[1]; [1]Rockefeller University, New York, NY, [2]National Heart, Lung, and Blood Institute, NIH, Bethesda, MD, [3]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT.

The LIM domain is a protein-interaction module that is implicated in cellular mechanosensation through the actomyosin-adhesion system. However, the molecular mechanism by which LIM proteins transduce mechanical signals remains elusive. Motivated by the hypothesis that mechanical deformations of actin filaments could serve as an upstream signal in mechanotransduction, we performed an imaging-based

screen for LIM-domain proteins that accumulate on stress fibers in cells exposed to cyclic stretch ("mechanoaccumulate"). Three LIM-domain protein families, FHL, paxillin, and zyxin, emerged as mechanosensors. We identified a highly conserved phenylalanine present in mechanosensor LIM domains, and demonstrated that mutating this phenylalanine in each LIM domain abolishes the mechanoaccumulation of LIM proteins on stress fibers. We developed an in vitro actin force reconstitution assay wherein actin filaments are exposed to forces generated by surface-immobilized myosin motors, which reveals that strain in single actin filaments is necessary and sufficient for FHL, paxillin, and zyxin binding. FHL2 is a transcriptional coactivator which has been reported to translocate to the nucleus in soft environments to upregulate its transcriptional targets. We hypothesized that force-induced conformational changes in F-actin could generate binding sites for FHL2 in stiff microenvironments, serving as a platform for retaining FHL2 in the cytoplasm and preventing its nuclear shuttling. We found that our FHL2 mutant exhibits enhanced nuclear enrichment compared with wild-type in cells plated on stiff substrates. Furthermore, live cell imaging reveals nuclear translocation of wild-type FHL2 upon cytochalasin D treatment to disrupt F-actin and its return to the cytoplasm upon drug washout, consistent with our hypothesis. Our results demonstrate a novel mechanotransduction mechanism mediated by the direct binding of FHL proteins to strained actin.

GFP-based F-actin Orientation Probes for Fluorescence Polarization Microscopy and Speckle F-actin Orientation Imaging in Living Cells.

N. NAKAI[1,2], K. Sato[1,2], T. Tani[3], K. Saito[1,2], F. Sato[1,2], S. Terada[1,2]; [1]Department of Neuroanatomy and Cellular Neurobiology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Tokyo, JAPAN, [2]Center for Brain Integration Research, Tokyo Medical and Dental University, Tokyo, JAPAN, [3]Eugene Bell Center for Regenerative Biology and Tissue Engineering, Marine Biological Laboratory, Woods Hole, MA 02543, MA.

Fluorescence polarization microscopy (FPM) is useful for detecting both positions and orientations of fluorescently labeled molecules and is thus expected to provide novel insights into the architectural dynamics of labeled cellular proteins. For example, when F-actin is appropriately labeled with fluorescence, FPM enables us to resolve the spatial organization of F-actin in its dense networks, and even the orientation of a single actin filament can also be determined. Although observation of actin with FPM has been commonly performed by fluorescent dye-conjugated phalloidin, there are several disadvantages for its use in live-cell FPM e.g. requirement of cumbersome microinjection and stabilization of actin filaments caused by phalloidin which may compromise the physiological actin dynamics. These disadvantages have greatly limited the application of FPM to live-cell imaging of actin, therefore novel actin probes for FPM are required. GFP-based actin probes, such as Lifeact-GFP, have been widely used, and some of them have been reported to have relatively small effects on the actin dynamics, but the fluorescence polarization of these probes does not reflect the orientation of actin since a flexible linker is usually used to connect the fluorescent protein to the actin-binding molecule. To develop GFP-based actin probes suitable for FPM, we rigidly connected circular permutated green fluorescent protein (cpGFP) to the N-terminal α-helix of actin-binding protein Lifeact or utrophin calponin homology domain (UtrCH), and normal mEGFP to the C-terminal α-helix of UtrCH. We expressed these constructs in cultured cells and evaluated their performance in FPM observation. Among them, some of the mEGFP-UtrCH constructs labeled actin filaments anisotropically, and showed low cytosolic background signal, enabling our successful speckle F-actin orientation imaging. We

conclude that these mEGFP-UtrCH constructs would be useful actin probes for F-actin orientation imaging with FPM, including speckle F-actin orientation imaging.

P78/B80

Structural Insights into Actin-binding Mechanisms Using Novel Fluorescence Technology for Spectrin Superfamily Members.

A. W. Avery[1], M. E. Fealey[2], **N. R. Billings**[1], S. A. Denha[1], R. T. Rebbeck[2], B. Svensson[2], A. An drick[2], D. D. Thomas[2], T. S. Hays[2]; [1]Oakland University, Rochester, MI, [2]University of Minnesota, Minneapolis, MN.

We seek to understand the molecular mechanisms by which cytoskeletal proteins of the spectrin superfamily bind to actin, with the ultimate goal of therapeutic discovery for a wide range of cytoskeletal and neurological disorders. Recently we found that a disease-causing missense mutation, L253P, in the actin-binding domain (ABD) of β-III-spectrin, causes a 1000-fold increase in actin affinity. The high conservation of L253 in other spectrin family members suggests that this residue has a conserved role in regulating actin binding. The objective of this project was to test whether residues at the equivalent position of L253 regulate actin binding in other ABDs. To test this we developed a novel FRET biosensor that monitors the binding of spectrin family members to actin in live cells. Using this assay, we found that mutation of the equivalent residue (M240P) in α-actinin-4, a founding member of the spectrin superfamily, does not increase actin binding. Structural analyses suggest that β-III-spectrin L253 coordinates a lysine residue (K65), which forms a salt bridge between the two calponin homology (CH) subdomains comprising the ABD. In α-actinin-4, this salt bridge is absent, with alanine in place of lysine. We hypothesize that lysine 65 is an important structural residue in β-III-spectrin that negatively regulates actin binding, together with leucine 253. To test this, lysine 65 was mutated to alanine, and actin affinity of the mutant determined by FRET in live cells and in *vitro*. Co-sedimentation assays showed that the K65A mutant ABD has higher F-actin binding affinity (Kd = 4.2 μM) than the wild-type ABD (Kd = 75 μM). FRET assays confirmed increased actin binding in live cells. Further, circular dichroism spectroscopy showed that the K65A mutation destabilizes the ABD, similar to L253P. This suggests that increased actin binding caused by the K65A mutant reflects an opening of the CH1-CH2 interface. These data indicate that lysine 65, together with leucine 253, negatively regulates actin binding in β-III-spectrin. Moreover, this study demonstrates that lysine 65 represents a key structural difference between β-spectrin and α-actinin. This study paves the way for structure-based drug discovery for treatment of disorders involving actin-binding proteins in the spectrin superfamily, such as spinocerebellar ataxia type 5, cardiomyopathies, and focal and segmental glomerulosclerosis.

P79/B81

Single-molecule Characterization of F-actin Velocities in Living Cells.

C. Miller, A. Dunn; Stanford University, Stanford, CA.

Active flows within the actin cytoskeleton generate mechanical forces that allow cells to migrate, change shape, and exert mechanical forces on their surroundings. In theory, the distribution of F-actin velocities should contain rich information about the structure and dynamics of the local actin cytoskeleton. However, most previous measurements report only average F-actin speeds. This limitation reflects in large part the low signal-to-noise ratio of typical F-actin tracking measurements, as localization errors on individual fluorescent fiducials are often comparable to the distances traveled between frames. Here, we describe a to our knowledge novel analysis that circumvents this issue by the deconvolution of

measurement noise from the measured velocity distributions of individual F-actin fiducials. This analysis yields F-actin velocity distributions that, unlike means, allow us to test physical models of force propagation through the actin cytoskeleton. We anticipate that this approach may be useful in the analysis of other single-molecule measurements that face limitations imposed by low signal-to-noise ratios.

Vrp1/WIP Activates Wsp1/WASp Nucleation Promoting Factor Activity at Sites of Endocytosis in Fission Yeast.

C. D. MacQuarrie, M. James, V. Sirotkin; SUNY Upstate Medical University, Syracuse, NY.

Arp2/3 complex-mediated branched-actin nucleation is important across species for cell motility and endocytosis. Branched actin assembly is stimulated by Nucleation Promoting Factors (NPFs), such as Wiskott-Aldrich Syndrome protein (WASp). WASp works in complex with WASp Interacting Protein (WIP), which protects WASp from degradation in mammals. Human patients with mutations in either WASp or WIP develop Wiskott-Aldrich Syndrome, a serious immune disorder. An important unresolved question is how branched actin assembly machinery is regulated and positioned to efficiently drive membrane deformation. We investigate mechanisms of branched actin assembly in a favorable model system, endocytic actin patches in fission yeast *S. pombe*. Here WASp homologue Wsp1 remains stable in the absence of WIP homologue verprolin Vrp1, providing an ideal environment to study WIP/Vrp1 function. Wsp1 and Vrp1 exist in a transient complex with myosin-1 Myo1 where Wsp1 and Myo1 activate the Arp2/3 complex to form the branched actin network necessary to internalize endocytic structures. *S. pombe* Vrp1 enhances Myo1 NPF activity in *vitro*, but its physiological role remains unknown. To uncover the role of Vrp1 on actin patch assembly in *vivo*, we generated internal domain deletions in the *vrp1*$^{+}$ gene, expressed these mutations under the endogenous promoter in cells expressing endocytic proteins tagged with fluorescent mGFP, and examined the effects of these mutations on endocytic patch dynamics using quantitative spinning disk confocal microscopy. We found Vrp1 localization to sites of endocytosis is entirely dependent on its C-terminal WASp Binding Domain (WBD). Additionally, using an in *vivo* protein binding assay, we discovered the Vrp1 Proline Rich Domain (PRD) directly binds the Myo1 tail, independent of Wsp1. When this Wsp1-Vrp1 interaction is disrupted by removing the Vrp1 WBD, the number of actin molecules localized to sites of endocytosis is significantly reduced. Surprisingly, removal of the Myo1-interacting PRD or the actin binding WH2 domains did not impact actin patch accumulation, suggesting Vrp1 activates Wsp1 NPF activity independent of the PRD and WH2 domains. This reduced accumulation of actin correlates with a reduction in the distance endocytic vesicles internalize, suggesting Vrp1 activation of Wsp1 provides force needed for membrane deformation. Further, using a novel in *vivo* actin polymerization assay, we observed the Vrp1 WBD, but not the PRD or WH2 domains, was necessary to enhance Wsp1 mediated actin assembly. This data provides novel evidence that Vrp1 regulates endocytosis by activating Wsp1 NPF activity.

CD2AP Links Actin to PI3 Kinase Activity to Extend Epithelial Cell Height and Constrain Cell Area.

Y. Wang, W. M. Brieher; Department of Cell and Developmental Biology, University of Illinois, Urbana-Champaign, IL.

<META NAME="author" CONTENT="华硕"> Epithelial cells generate three different membrane domains (apical, basal, and lateral) that perform distinct functions. The ratios of apical and basal membrane to lateral membrane varies between cell types depending on physiological function, but little is known as to what controls the height of the lateral membrane relative to the area of the apical and basal domains. Here, we show that the actin-binding scaffold protein, CD2AP, is a critical determinant of epithelial proportions. Depletion of CD2AP or PI3-kinase inhibition results in loss of F-actin and expansion of apical-basal domains which comes at the expense of lateral membrane height in MDCK cells. Immunofluorescence staining showed that CD2AP co-localized with PI3K p85α. CD2AP is required for PI3K p85α and p110γ recruitment and PtdIns(3,4,5)P_3 synthesis along lateral membranes. Thermophoresis results showed that SH3 domains (1-329 a.a.) of CD2AP binds to the N-terminus of PI3K p85α (1-315 a.a.) which contains two proline-rich motifs. Targeting SH3 domains (1-329 a.a.) of CD2AP to lateral membrane was sufficient to restore p85α and p110γ membrane levels. CD2AP 1-329 a.a. or PI3K p110 γ membrane tethering both recovered F-actin accumulation and apical expansion in CD2AP-knockdown MDCK cells. SH3 domains of CD2AP contributes to both PH-GFP fluorescence signals generation along cell borders and constraining cell spreading area. Thus, CD2AP recruits PI3K to regulate cell height. We also showed that CD2AP is not actin monomer sequester, but directly associates with F-actin and regulates actin dynamics in *vitro*. Single filament elongation experiments showed that both NT- and CT- of CD2AP decreased actin polymerization rates. In *vivo*, Latruculin B treatment attenuated both CD2AP and PI3K levels, i.e. CD2AP and PI3K are both upstream and downstream of actin polymerization. Thus we hypothesized that CD2AP bridges actin assembly to PI3K activation to form a positive feedback loop to support lateral membrane extension. Our results may provide insights into squamous to cuboidal to columnar epithelial transitions seen in complex epithelial tissues in *vivo*.

The Chytrid Fungus *Batrachochytirum Dendrobatidis* Has Both an imal-like and Yeast-like Actin Networks.

S. Prostak, L. Fritz-Laylin; University of Massachusetts Amherst, Amherst, MA.

The frog parasite Batrachochytirum dendrobatidis (Bd) is a chytrid fungus with two main life stages, a motile zoospore stage lacking a cell wall, and an immotile zoosporangia stage with a chitin cell wall. We have previously shown that Bd zoospores move on surfaces using actin and Arp2/3 dependent cell protrusions called pseudopods. Because this motility is likely involved in pathogenesis, it is important to understand how pseudopods and other actin structures are regulated in Bd. To understand the possible mechanisms Bd may be using to control its actin networks, we used BLAST searches to determine the conserved set of actin regulatory proteins present in Bd and other chytrid fungi. We found that chytrids have an actin regulatory protein repertoire intermediate to that of animals and that of other fungi. For instance, chytrids encode the canonical actin nucleators Arp2/3 complex and formins, and, unlike other fungi, also encode the Arp2/3 regulator, SCAR/WAVE complex. Given chytrids' divergence before the diversification of fungi, this finding gives fundamental insight into the evolution of actin regulatory networks. Through a combination of phalloidin staining and small molecule inhibitors, we found that Bd

has temporally and phenotypically distinct actin structures which resemble either those of animals or of yeast. The finding of animal-like and yeast-like actin structures present in one organism proves useful in uniting the two main model systems of actin study. Furthermore, expanding the knowledge of actin-based motility in Bd brings us closer to finding a way to combat the devastating effects this pathogen has on amphibian populations worldwide.

To Elucidate Hyaluronan Mediated Motility Receptor Mediated Daughter Cell-size Control Pathways during Mitosis.

L. Mei, M. Connell, C. Kuan, P. Lange, C. Maxwell; University of British Columbia, Vancouver, BC, CANADA.

Background: Cell division must evenly distribute genetic information between two daughter cells with equivalent size and cytoplasmic factors. These processes rely upon the position of the spindle during anaphase. Spindle position is regulated by dynein-dependent cortical pulling forces and, when the anaphase spindle is off-centered, asymmetric membrane elongation (AME). During AME, Ran-GTP at chromosomes is brought proximal to the cortex and induces rapid membrane blebs due to actomyosin-based contractile forces on one side of the plasma membrane, altering cellular boundary to correct daughter cell size. HMMR is known to regulate the establishment of proper spindle position. HMMR locates Ran-GTP to the centrosome as part of a polo-like kinase1 (PLK1)-dependent spindle positioning pathway; therefore, we investigated whether HMMR also regulates AME during cell division and affects daughter cell-size control. **Methods:** Overexpression and knockdown of HMMR in HeLa cells were achieved by tetracycline inducible system (tet-GFP-HMMR-HeLa) and siRNA, respectively. Live cell imaging was used to track membrane blebbing and daughter cell-size. IP-MS was used to identify potential actin-related binding partner of HMMR during mitosis. The localization and abundance of actin-binding proteins during mitosis were determined using super-resolution fluorescence microscopy. Candidate kinases known to regulate daughter cell-size control were modulated with sublethal (0.01 X IC50 dose) doses of small molecule inhibitors. **Results:** tet-GFP-HMMR-HeLa cells showed more frequent mispositioned anaphase spindles, a higher occurrence of AME during anaphase and unequal daughter cell ratios. IP-MS of HMMR during mitosis identified a set of actin-binding proteins, Arp3, NMIIb and MYO18A. Arp3 co-localized with HMMR at the spindle pole during anaphase and the cortical localization of Arp3 was affected in tet-GFP-HMMR-HeLa cells. Mild inhibition of Aurora a (but not PLK1, Aurora B, or CK1) was sufficient to dampen kinase activity at spindles poles, as measured by immunofluorescence, and also partially rescued Arp3 cortical recruitment, AME and daughter cell-size control in tet-GFP-HMMR-HeLa cells. **Conclusion:** GFP-HMMR overexpression during mitosis induces AME and deregulates daughter cell-size control. Mechanistically, the inhibition of Aurora a kinase partially rescued these phenotypes and Arp3 cortical localization implicating augmented kinase activity as a contributing factor downstream GFP-HMMR overexpression that deregulates AME and daughter cell size control. Direct interaction between HMMR and Arp3 is an additional putative factor that is currently under investigation.

How Do Cells Move in Our Body? Study of the Cellular Mechanisms Allowing Immune Cell Migration in Restricted Spaces.

L. Barbier[1,2,3], P. J. Saez[1,2], R. Attia[1,2], I. Lavi[1,2], M. Piel[1,2], P. Vargas[1,2]; [1]Institut Curie, PSL Research University, CNRS, UMR 144, Paris, FRANCE, [2]Institut Pierre-Gilles de Gennes, PSL Research University, Paris, FRANCE, [3]Université Paris-Sud, Université Paris-Saclay, Orsay, FRANCE.

Upon infection, mature dendritic cells (mDCs) migrate from peripheral tissue to lymph nodes to activate T lymphocytes and initiate the adaptive immune response. This fast and tightly regulated process imposes a series of physical constraints and is tuned by different microenvironmental factors, such as the physical properties of the tissue[1]. Mechanistically, mDCs migration relies on acto-myosin flow and contractility, which are dependent on non-muscular Myosin IIA (MyoII) activity. However, the specific mechanoresponse that allows mDCs to adapt their migration machinery to irregular 3D landscapes has not been fully characterized. In this work, we combined a series of approaches, from micro-fabricated devices to ex vivo skin models, to dissect the cytoskeleton rearrangements used by mDCs to overcome the physical barriers imposed by the tissue microenvironment[2]. By using microchannels of different sizes, we have shown that mDCs are able to maintain a constant speed while migrating at different levels of confinement. This reveals the extreme capacity of mDCs to adapt their migration machinery in response to changes in the geometry of their microenvironment[3]. At the cellular level, confinement in microchannels induces a fast and specific acto-myosin remodelling in mDCs. Upon cell compression, polymerized cortical actin concentrate in two areas of the cell: 1) at the extreme back and 2) at the cell centre, where the microtubule organizing centre and the lysosomes localized. The structure at the back is associated with MyoII and is required to maintain mDCs speed in narrow and irregular landscapes. Interestingly, preliminary data shows that the polymerized actin structure at the cell centre is important to maintain cellular integrity while mDCs move in irregular 3D microenvironment. Altogether, our results reveal a complete acto-myosin rearrangement triggered by confinement, which is essential for mDCs migratory plasticity that allows these cells to move in intricate 3D geometries. The full understanding of how mDCs and other leukocytes adapt their motility to specific tissue structures will provide better knowledge on how cell migration is controlled in confined spaces and new insight to finely tune their migration to promote or prevent immune responses. 1. Actin Dynamics for Efficient Phagocytosis: Mechanosensitivity and New Regulators.

A. Mularski[1], F. Herit[1], C. Le Clainche[2], M. Balland[3], **F. Niedergang**[1]; [1]Institut Cochin (Inserm U1016, CNRSUMR8104, Universite Paris Descartes), Paris, FRANCE, [2]2Department of Biochemistry, Biophysics and Structural Biology , Institute for Integrative Biology of the Cell, Gif-sur-Yvette, FRANCE, [3]3Laboratoire interdisciplinaire de Physique, Université Joseph Fourier, Grenoble, FRANCE.

Phagocytosis is a mechanism of internalization and degradation of micro-organisms or cellular debris. Phagocytosis is important for remodelling of tissues, disposal of dead cells and bacterial clearance. Actin polymerisation provides the force that drives the membrane deformation required to engulf particulate matter during phagocytosis. We identified new actin regulating proteins that are recruited at sites of membrane extensions and phagosome closure. We showed that they are crucial for efficient uptake of various particles and bacteria. Key to dissecting the mechanism by which this occurs, is understanding how the complex mechanosensitive machinery of actin binding proteins sense force and stabilize actin anchoring during phagocytosis, from initial receptor binding, through to phagosome formation and closure. A novel experimental approach utilizing traction force microscopy is being used to observe phagocytosing macrophages on substrates of biologically relevant stiffness. We show that the capacity of macrophages to perform efficient phagocytosis varies with the substrate stiffness. In addition, phagocytosing macrophages display different properties such as contractile energy and polarization degree as compared with non-phagocytosing cells. The mechanotransduction pathways implicated will be discussed.

Optical Flow Techniques Reveal Differences in Actin Wave Guidance Across Scales.

R. M. Lee[1,2], L. J. Campanello[1], M. J. Hourwitz[1], J. T. Fourkas[1], W. Losert[1]; [1]University of Maryland, College Park, MD, [2]University of Maryland School of Medicine, Baltimore, MD.

Understanding the rearrangements of the cytoskeleton is essential to developing a complete picture of dynamic cellular processes, such as migration, division, and differentiation. Here we focus on the role of the extracellular environment as an important modulator of actin dynamics. In addition to often-studied biochemical cues, the extracellular environment also provides physical cues such as the topography of the extracellular matrix (ECM). We show that topographical cues are capable of guiding both cell migration and actin dynamics in multiple cell types. Periodic surface topographies with feature sizes comparable to those of in *vivo* collagen fiber networks guide actin dynamics bidirectionally. We show that such subcellular-scale guidance can be exploited to create unidirectional guidance of both actin and cell migration through periodically repeating local asymmetries. We find that for a given asymmetry, the preferred direction of both actin waves and motion is dependent on cell type. To quantitatively distinguish actin dynamics phenotypes in response to surface topography, we have adapted a computer vision algorithm, optical flow, which allows us to determine the direction of actin waves at the microscale (individual pixels). This quantitation allows us to compare two cell types with markedly different migratory modes and physiological purposes, slowly migrating epithelial MCF10A cells and fast migrating neutrophil-like HL60 cells. Though they have distinct morphodynamics, optical flow measurements indicate that both cell types exhibit guided one-dimensional actin waves (esotaxis) on periodic surface topographies. However, clustering the optical flow vectors into regions with similar flow directions shows that the mesoscale features of actin dynamics are cell type dependent. These results suggest that esotaxis is a common cellular process, yet the details of the esotactic response exhibit quantitative differences among cell types that can be exploited to achieve goals such as cell type dependent unidirectional guidance.

Mechanically Induced Activation of Actin Elongation Factor Dia1 at Focal Adhesions Protects the Cytoskeleton from Damage and Facilitates Stress Fiber Repair.

F. R. Valencia[1], J. Liu[2], S. V. Plotnikov[1]; [1]University of Toronto, Toronto, ON, CANADA, [2]Johns Hopkins, Baltimore, MD.

Cells are truly the ultimate "smart material" regulating their mechanical properties dynamically and locally to match mechanical demands of their microenvironments. Such plasticity of cell mechanics relies on the regulation of the structure and dynamics of cell cytoskeleton. Contractile forces exerted by myosin II on actin filaments are known to regulate cytoskeleton dynamics, but the mechanism remains poorly understood. Here we show that myosin contractility regulates actin cytoskeleton dynamics by enhancing the activity of actin elongation factor Dia1 at focal adhesions, an integrin-based protein assembly that link cell cytoskeleton to the extracellular matrix. We show that this mechanism works as a 'safety valve' restricting mechanical tension on the stress fibers and protecting actin cytoskeleton from mechanical damage. By combining live-cell imaging and pharmacological manipulations, we assessed how suppression of major actin elongation factors affects the rate of actin polymerization at focal adhesions. We found that formin inhibition decreased polymerization by ~ 60%. By depleting individual formins, we identified Dia1 as the major actin elongation factor at focal adhesions. To understand the role of mechanical forces applied to formins we used pharmacological perturbation of myosin II to attenuate contractility within the cell. We found a dose-dependent decrease in actin polymerization at focal adhesions as myosin contractility was suppressed by ≈90%. The regulation of actin polymerization by myosin contractility was abolished in cells depleted of Dia1, indicating that contractility modulates Dia1 activity. By using a novel super-localization technique, we visualized instantaneous rate of actin polymerization at focal adhesions and showed that Dia1 activity is not constant but undergoes myosin-dependent cyclical events. To investigate the biological role of myosin dependent Dia1 activation, we assess how depletion of Dia1 affects the integrity and repair of actin cytoskeleton. We found that suppression of actin polymerization at focal adhesions increases the magnitude of spontaneous stress fiber damage and decreases the efficiency of zyxin-mediated stress fiber repair. As actin filaments are subject to complex mechanical constraints in living cells, these results provide important insights into how formins sense these mechanical constraints and regulates actin organization to prevent damage.

Spine Segmentation Is Regulated by Mechanical Coupling of the Notochord Sheath and Myosepta.

S. Wopat, M. Bagnat; Duke University, Durham, NC.

In zebrafish, segmentation of the notochord epithelial sheath provides a template for osteoblast recruitment and vertebral bone formation in the developing spine. While notochord segmentation seems to follow a tissue-autonomous program, the precise positioning and size of its segments is influenced by interactions with the adjacent, tendon-like myosepta, which arise from the somite boundaries. However, how the interaction between tissues modulates notochord segmentation is unclear. To investigate how myosepta regulate notochord segmentation, we generated novel transgenic tools to monitor localization of mechanosensing proteins and contractile machinery in the notochord sheath. Using live-imaging approaches, we observed that initiation of notochord segments occurred next to myosepta and was accompanied by the nucleation of stable, tension-sensitive protein clusters. In contrast, fish with disrupted myosepta lacked segmented localization of these clusters and failed to

precisely space notochord segments. Furthermore, enrichment of mechanosensing complexes suggested that transduction of mechanical cues from the myosepta promoted assembly of contractile machinery in the notochord sheath. Live-imaging of newly developed reporters for non-muscle myosin and F-actin revealed the formation of cortical actomyosin networks in new and presumptive segments. When recruitment of contractile machinery was prevented in the notochord sheath, segment size and morphology was affected, suggesting that cortical forces within notochord sheath cells regulate tissue patterning. Together, these findings reveal that mechanical coupling of the notochord and the myosepta promote precise notochord segmentation through localized activation of intracellular cortical contractile networks.

A New Biomechanical Mathematical Model of Force Effects on Actin Dynamics during Clathrin-mediated Endocytosis.

R. Ray[1,2], J. Berro[3,4,2]; [1]Yale College, Yale University, New Haven, CT, [2]Nanobiology Institute, West Haven, CT, [3]Department of Molecular Biophysics and Biochemistry, Yale University, New Haven, CT, [4]Department of Cell Biology, Yale University, New Haven, CT.

Background: During clathrin-mediated endocytosis, actin filaments assemble into a network that experiences and generates force. However, the interactions between the mechanical and chemical aspects of endocytic proteins remain unclear. This study proposes a new biomechanical approach to model how the actin filament network composition responds to different load forces in yeast. **Methods:** the biochemical component of the model was a system of ordinary differential equations representing key reactions involved in actin assembly/disassembly previously validated with in *vivo* yeast data. We added mechanical relationships to the reactions using alternative hypotheses of load force changes over time. The Arrhenius/Bell equation was used to specify an inverse relationship between load force and the actin polymerization rate constant. We assessed two different hypotheses. In the “constant load model”, the load force remains constant throughout endocytosis. In the “variable load model”, the polymerizing actin filaments increase the load force, creating a negative feedback loop: as more filaments polymerize, the load force increases, inhibiting polymerization. We simulated the time evolution of the components of the actin filament network including F-actin and capped filament ends (capping protein). We assessed model performance using two criteria: the number of peaks and the peak value of the time evolution of the copy number of each protein. **Results:** at load forces < 0.1pN, the F-actin time evolution had one peak under both models at forces > 0.1pN, the F-actin time evolution had two peaks under the “variable load model” - a pattern which is not seen in wild type but may be seen in mutant cells. Under the “constant load model”, the F-actin time evolution had one peak for a wide range of forces except for high forces when polymerization was completely inhibited. At forces < 0.02pN, both models had similar peak values for each protein and the F-actin and capped filaments/capping protein peak values were close to experimentally measured values. Under both models, the direction of change in peak value was the same and the peak number of polymerizing filaments, normalized to the peak number of branches monotonically decreased with increasing load force, explaining the monotonic decrease in F-actin. **Conclusion:** This new biomechanical modeling approach suggests that force feedback could possibly regulate actin assembly/disassembly and may vary with different load forces. In *vivo* experiments with varying load forces may allow us to confirm the force dynamics during the biochemistry of actin assembly/disassembly predicted by this model.

P91/B93

Arp2/3 Complex and Myosin2 Motor Activity Drive F-actin Mediated Microvilli Motility on Insulin Secreting INS-1 Cells as Revealed by TIRF-SIM Super Resolution Live Cell Imaging.

T. Woellert[1], E. Wait[2], M. Gandikota[3], J. M. Schwarz[3], T. Chew[2], G. M. Langford[1]; [1]Department of Biology, Syracuse University, Syracuse, NY, [2]AIC, Howard Hughes Medical Institute, Janelia Research Campus, Ashburn, VA, [3]Physics Department, Syracuse University, Syracuse, NY.

Microvilli are cell surface protrusions consisting of a core bundle of actin filaments that are linked to the cortical actin network and plasma membrane via actin binding proteins. Epithelial cells generate arrays of microvilli known as brush border that function to increase solute uptake. Pancreatic beta cells also elaborate microvilli that serve as the primary site of the GLUT2 glucose transporter for glucose uptake. However, the dynamic changes that microvilli undergo during insulin secretion in pancreatic beta cells is not understood. We used super resolution TIRF-SIM microscopy to study the dynamics of microvilli during exocytosis in living pancreatic beta cells (INS-1 832/13) transiently transfected with mEmerald-LifeAct. Time-lapse sequences generated with TIRF-SIM microscopy showed that microvilli are highly motile structures and translocate at a mean velocity of 67 nm/s across the cell surface of INS-1 cells. To analyze the motile behavior of microvilli under low glucose conditions, individual microvilli were tracked and resulting trajectories were subjected to rose plot and mean square displacement (MSD) analysis. Rose plots showed that microvilli exhibit long-range displacements and MSD analysis generated a parabolic curve suggesting directed movement. Bayesian Hidden Markov Modeling (HMM) validated that microvilli undergo directed movement with both diffusive and transport states. Co-expression of mEmerald-LifeAct and mCherry-ARP2 in INS-1 cells showed that Arp2 was highly enriched in motile microvilli. To determine whether movement of microvilli was due to an Arp2/3-mediated assembly mechanism, Arp2/3 activity was inhibited with CK666. Trajectory analysis showed that inhibition of the Arp2/3 complex changed the motile behavior and that microvilli exhibited short-range rather than long-range displacements at a reduced mean velocity of 23 nm/s. Similarly, inhibition of myosin2 with blebbistatin also caused slow and short-range displacements of microvilli. MSD and HMM Bayes analysis for CK666- and blebbistatin-treated cells indicated an increase in the directed diffusive motion state for motile microvilli. Stimulation of INS-1 cells with 20 mM glucose to secrete insulin also reduced the average velocities and path lengths of moving microvilli compared to low glucose conditions. MSD and HMM Bayes analysis showed that stimulation with 20 mM glucose resulted in an increase in directed diffusive motion state compared to low glucose conditions. We, therefore, conclude that Arp2/3-mediated actin nucleation and myosin2 motor activity drive the movement of microvilli and we hypothesize that the movement serves to enhance their sensory function in response to changes of glucose levels in pancreatic beta cells.

P92/B94

Actomyosin Dynamics Tune Excitable Rhoa Activity to Produce Distinct Spatiotemporal Modes of Pulsed Contractility in the *C. Elegans* Zygote.

B. Yao, M. Edwin; University of Chicago, Chicago, IL.

Pulsed contractility is a widespread form of actomyosin contractility in which actin filaments and myosin II undergo local cycles of assembly, contraction and disassembly, driven by locally pulsed activation of RhoA. Spatiotemporal patterns of pulsed contractility vary widely across different organisms and developmental contexts, but the origins of this variation are poorly understood. In early *C. elegans*

embryos, pulses are driven by locally excitable RhoA dynamics involving fast positive feedback and delayed negative feedback mediated by F-actin dependent recruitment of the RHO GAPs RGA-3/4. Dynamic coupling of F-actin to RhoA inhibition suggests that modulating actin network assembly, contractility and disassembly could provide a way to access different spatiotemporal modes of pulsed contractility. To explore this, we quantified variations in spatiotemporal pulse dynamics produced by tuning levels of maternal factors that regulate actin network assembly, contraction, cross-linking and disassembly. Tuning actin network dynamics has minimal effects on the local rise and fall of RhoA activity during individual pulses, but can induce large variations in the pattern and local timing of pulse initiation, and in the spread of RhoA activity that determines pulse size and shape. Across many different perturbations, the initiation and spread of RhoA activity correlates with patterns of F-actin accumulation. An alysis of these correlations suggests that much of the variation in spatiotemporal RhoA dynamics can be explained by two effects: (a) that local F-actin depletion favors local pulse initiation and (b) that local regions of high F-actin density limit its subsequent spread. For example, perturbations which favor local actin depletion at the end of pulses, either through local disassembly or contractile instability, promote locally oscillatory pulse dynamics, with a dominant period set by the local persistence of F-actin accumulation. Decreasing overall F-actin levels and/or creating larger zones of F-actin depletion favors more rapid spread of RhoA excitation and larger pulses. Strikingly, when myosin activity and F-actin density are both reduced, RhoA activity spreads as traveling waves, as observed in other contexts. These observations identify local inhibition by F-actin as a major factor in shaping spatiotemporal pulse dynamics.

P93/B95

The Cell Cycle Regulates Excitability of the Actin Cytoskeleton.

Z. Swider[1], G. von Dassow[2], W. Bement[1]; [1]University of Wisconsin - Madison, Madison, WI, [2]University of Oregon, Charleston, OR.

The actin cytoskeleton mediates a diverse array of cell shape changes, including cytokinesis. In *Xenopus laevis* (frog) and *Patiria miniata* (sea star) embryos, the actin cytoskeleton forms self-propagating waves of assembly and disassembly. Previous experimental results have shown that actin waves are preceded by waves of active Rho. Computational modeling suggests that these waves represent excitable dynamics of a reaction-diffusion system, with Rho behaving as the activator and F-actin behaving as the inhibitor. Strikingly, both wave sets are amplified by increased concentrations of the Rho GEF Ect2, a normal component of the centralspindlin complex and an essential cytokinetic regulator, suggesting a link between cortical waves and signaling from the spindle. We show that both Rho and F-actin waves are modulated by Cdk1 activity and are most apparent during cytokinesis phase of the cell cycle. Wave amplitude appears to be gated partially by the phosphorylation state of Ect2, and partially by cortical actin dynamics. We provide evidence that both of these factors feed into the mitotic regulation of cortical waves.

Actively-tuned Phase Transition in the Actomyosin Cortex.

V. T. Yan[1,2], A. Narayanan[1], S. Grill[1]; [1]MPI-CBG, Dresden, GERMANY, [2]TU Dresden, Dresden, GERMANY.

Phase transitions in biological contexts is thought to enable local enrichment reaction components, and has been suggested to contribute to construction of essential cellular architecture. F-actin filaments

make up the key architecture that is the cell's cortex. During the activation of the actomyosin cortex of the *C. elegans* embryo. Dynamic cortical F-actin puncta form and disassemble, with steady-state size distribution. The condensation of F-actin is preceded by nucleators WASP and Arp2/3.To study the dynamic clusters, the relative concentrations of WASP and F-actin over the lifetime of the puncta was tracked. The intensity evolution over the whole concentration landscape reveals that the growth rate of the cluster in WASP and F-actin is predicted by stoichiometry of the nucleators. The critical size of WASP condensates varies with F-actin levels. Condensation of WASP coupled to F-actin polymerization corresponds to cluster disassembly. Furthermore, the critical size of WASP condensates is tuned by F-actin condensation. Based on this relationship, we developed a model from which the direct rates can be measured from data. The model recapitulates the key characteristics of concentration evolution. This study reveals mechanisms that underly self-organization of protein condensates in the context of actin cortex remodelling.

The Huntingtin-interacting Protein Setd2/hypb Is an Actin Lysine Methyltransferase.

R. N. H. Seervai[1], R. K. Jangid[1], I. Y. Park[1], M. Karki[1], S. E. Kearns[2], D. N. Tripathi[1], R. Dere[1], K. J. Verhey[2], W. I. Russell[3], W. K. Rathmell[4], C. L. Walker[5]; [1]Baylor College of Medicine, Houston, TX, [2]University of Michigan, an n Arbor, MI, [3]University of Texas Medical Branch, Galveston, TX, [4]Vanderbilt University Medical Center, Nashville, TN, [5]Baylor College of Medicine, houston, TX.

SET-domain-containing-2 (**SETD2**) was originally discovered as Huntingtin Yeast Partner B (**HYPB**) due to its interaction in a yeast two-hybrid screen with the Huntingtin (**HTT**) protein. Later, SETD2 was identified as the methyltransferase responsible for trimethylation of histone 3 lysine 36 (**H3K36me3**), a mark of the histone code associated with active gene transcription. Most recently, SETD2 has been shown to bind microtubules and methylate α-tubulin at lysine 40 (**α-TubK40me3**) during mitosis and cytokinesis, with loss of SETD2 and a subsequent decrease in cytoskeleton methylation resulting in spindle defects and genomic instability. We have now discovered SETD2 associates with actin, another key component of the cytoskeleton, as part of an HTT complex containing the interacting partner **HIP1R**. HTT and its interacting partners regulate many actin-dependent processes, and we show here that as part of this complex, SETD2 functions as an actin methyltransferase. We found using in *vitro* methylation assays, the catalytic SET domain of SETD2 has intrinsic methylation capacity for actin, and antibodies directed against the trimethyl lysine epitope generated by SETD2 detected this mark on actin following in *vitro* methylation. To assess the relationship between SETD2 and actin methylation in cells, we used these SETD2 trimethyl epitope-specific antibodies to show that this epitope was present on actin from *SETD2*-proficient but not *SETD2*-deficient cells. The dependence on the SETD2-HTT-HIP1R complex for actin methylation was also demonstrated by knockdown of either *HTT* or *HIP1R*, which was sufficient to inhibit SETD2 binding and methylation of actin. SETD2 methylation was localized to areas of active cytoskeletal remodeling in cells, including the lamella/leading edge of migrating cells. Consistent with methylation at the leading edge, we identified a requirement for SETD2 in cell migration, and found biochemical and cellular evidence for an underlying F-actin polymerization defect following SETD2 loss. After its initial discovery as a Huntingtin-interacting protein, SETD2 has been the focus of studies related to its function on the epigenome. This work reveals for the first time an extended non-chromatin role for SETD2, and provides the first demonstration lysine methylation regulates the actin cytoskeleton. Localization of the SETD2 methyl epitope at the leading edge of cells, and disruption of actin polymerization and cell migration with loss of SETD2 points to a new role for SETD2 in regulation of the

actin cytoskeleton, expanding what is known about the key roles played by this methyltransferase in methylation of histones during transcription and spindle microtubules during cell division.

P96/B98

β-actin and γ-actin Nucleotide Coding Sequences Regulate Cell Migration Speed.

P. Vedula[1], S. Kurosaka[2], **A. Kashina**[1]; [1]University of Pennsylvania, Philadelphia, PA, [2]Kindai University, Osaka, JAPAN.

β- and γ-cytoplasmic actins are ubiquitously expressed in every cell type and are nearly identical at the amino acid level, but play vastly different roles in *vivo*. Their essential role in embryogenesis is defined largely by the nucleotide sequence of their genes, rather than their amino acid sequence, however it is unclear which gene elements underlie this effect. Here we address the specific role of the coding sequence in β- and γ-cytoplasmic actins' intracellular function, using stable cell lines with exogenously expressed actin isoforms and their "codon-switched" variants. When targeted to the cell periphery using the β-actin 3'UTR, β-actin and γ-actin have differential effects on cell migration. These effects are directly coding sequence-dependent. Our results link these effects to the rates of actin isoforms' intracellular accumulation that likely affects the morphology and turnover of focal adhesions, and suggest that coding sequence-mediated actin translation plays a key role in cell migration.

P97/B99

Two Distinct Populations of Actin Filaments Have Differential Effects on Mitochondria in Response to Differing Stimuli.

T. Fung[1], W. Ji[2], H. N. Higgs[1], R. Chakrabarti[1]; [1]Geisel School of Medicine at Dartmouth, Hanover, NH, [2]Huazhong University of Science and Technology, Wuhan, CHINA.

Over the years, mitochondria have graduated from being merely bioenergetic supply stations to discrete signaling organelles. Increasing evidence suggests that actin polymerization participates in mitochondrial communication and dynamics. In this study, we attempt to differentiate specific mitochondrially-associated actin filaments, their mode of organization and the effects they have on the mitochondria. We find at least two distinct modes by which actin and mitochondria interact. In one mode, elevation of cytosolic calcium activates endoplasmic reticulum (ER)-bound formin INF2, and the resulting ER-based actin polymerization stimulates two distinct events for subsequent mitochondrial division. First, an increase in transfer of calcium from ER to mitochondria results in inner mitochondrial membrane (IMM) constriction. Second, actin assembly promotes Drp1 recruitment to the outer mitochondrial membrane (OMM), which results in OMM constriction. In the other mode, dissipation of the mitochondrial proton gradient ('depolarization') causes an extensive 'cloud' of actin filaments around the depolarized mitochondria within 10 min. This actin assembly is dependent on the Arp2/3 complex but not on INF2. On a similar time scale after depolarization, mitochondria undergo extensive shape changes. Two aspects of these shape changes are surprising: 1) they are not primarily due to mitochondrial fission, and 2) they are not dependent on actin cloud assembly. The major component of the shape change is rearrangement of the IMM, resulting in a circularization of the IMM while maintaining the integrity of the OMM. Correspondingly, the shape changes depend upon the IMM protease Oma1, but not on the Drp1 GTPase. Actin clouds actually inhibit mitochondrial shape changes, suggesting that these clouds play a protective role for the depolarized mitochondria or for the rest of the cell. Actin clouds also suppress events downstream of depolarization, such as PARKIN accumulation. In summary, we show

that there are two distinct types of actin filaments assembly and they differ in their morphology, assembly mechanisms and effects on mitochondria.

The Formin Fmnl3 Participates in Depolarized Induced Actin Assembly Around Mitchondria.

R. Chakrabarti, T. Fung, H. Higgs; Geisel School of Medicine at Dartmouth, Hanover, NH.

A growing number of studies suggests that actin polymerization participates in mitochondrial communication and dynamics in mammalian cells. We find that there are at least two distinct modes by which actin and mitochondria interact. In one mode (Chakrabarti et al (2019) *J. Cell Biol.* 217(1): 251-268), elevation of cytosolic calcium activates the endoplasmic reticulum (ER)-bound formin INF2, and the resulting actin polymerization stimulates two distinct events that promote mitochondrial fission: increased transfer of calcium from ER to mitochondria, (resulting in IMM constriction); and Drp1 recruitment to the outer mitochondrial membrane (OMM), resulting in OMM constriction. In the other mode (Fung et al (2019) *Biorxiv* 701771), dissipation of the mitochondrial proton gradient ('depolarization') causes rapid accumulation of an extensive 'cloud' of actin filaments around the depolarized mitochondria, dependent on Arp2/3 activity. Importantly, while this second mode is INF2-independent, multiple studies suggest that one of the remaining 14 formins is involved. By siRNA screen, we find that inhibition of FMNL3 in U2OS cells significantly reduces depolarization-induced actin assembly. In contrast, depolarization-induced actin polymerization is maintained upon knock-down of FMNL1, FMNL2, mDia1, mDia2, and INF2. The effect of FMNL3 KD is somewhat different from Arp2/3 complex inhibition, in that weak actin filament accumulation persists, but is greatly reduced and often does not encompass majority of mitochondrial network, a feature of depolarization-induced actin clouds. While FMNL3 participates in depolarized-induced actin assembly, it did not have any role in calcium-induced, INF2-dependent actin assembly. Mitochondrial depolarization also results in extensive mitochondrial shape changes that are due to reorganization of the inner mitochondrial membrane. These mitochondrial shape changes are independent of actin polymerization or Arp2/3 complex. In fact, pharmacological inhibition of Arp2/3 complex or knock-down of FMNL3 causes an increase in depolarization-induced mitochondrial shape changes. We propose that rapid actin polymerization around depolarized mitochondria acts as a protective mechanism, allowing for mitochondrial recovery.

Dynamic Organization of the Cortical Actin Network and Plasma Membrane Inner-leaflet through Action of Formins and Class I Myosin Motors.

T. S. van Zanten, P. Sil, S. Mayor; National Centre for Biological Sciences, Bangalore, INDIA.

The outer membrane of the living cell is the interface that demarcates the cell and its environment. The chemistry of the plasma membrane is largely build up from lipids and proteins and local organization of this chemistry primes the cell to adapt and react to the external milieu. Experimental data [1] and a theoretical framework [2] have largely argued to view the plasma membrane and the closely juxtaposed dynamic actin-based cortical layer as an active composite. Cells consume energy to mechanically restructure this active composite by the action of actin filament nucleators and motors, which often bind to negatively charged phospholipids in the inner-leaflet to mediate remodelling of the cytoskeleton close to the plasma membrane. Here we focus on the role of class I non-muscle myosin molecular motors and formin actin nucleators in organizing the active composite at the plasma membrane. Both

formin and myosin I bind to negatively charged phospholipids at the plasma membrane and have the capacity to actively remodel actin filaments [3,4]. Using structured illumination microscopy to follow actin dynamics we find that formins and to a lesser extent myosin class I motors decrease the remodelling rates and dynamics of the cortical actin meshwork. Phosphatidylserine at the inner leaflet of the plasma membrane has been shown to be important for the trans-bilayer interaction of lipid-species at the outer leaflet, and its link to the dynamic cortical actin present at the inner leaflet. By using fluorescence correlation spectroscopy we find that levels of phosphatidylserine, at the inner leaflet, also regulates the organization and function of both formins and myosin I motor proteins, in turn helping to couple actomyosin activity and lipid organization at the plasma membrane. Together, our results provide evidence for a key role for both formins and non-muscle class I myosin motors in driving and maintaining the active composite that is constituted by the actin cortex interacting with the plasma membrane. Synergistic 330-foldPointed-end Actin Depolymerization by Cyclase-associated Protein and Cofilin.

S. Shekhar, J. Chung, J. Kondev, J. Gelles, B. Goode; Brandeis University, Waltham, MA.

Living cells can rapidly disassemble and remodel actin networks in a few seconds, yet in *vitro* actin filaments take several minutes to depolymerize. Cellular mechanisms that can depolymerize actin this fast have thus far remained obscure. Using microfluidics-assisted TIRF and single molecule imaging, we have discovered a multicomponent system in which cyclase-associated protein (CAP) and Cofilin synergize to enhance actin depolymerization by 330-fold. Hexameric CAP molecules transiently interact with pointed ends of cofilin-decorated filaments and remove approximately 100 actin subunits per binding event. These are the fastest rates of actin depolymerization ever reported in *vitro*. We further show that CAP-cofilin synergy has been conserved across a billion years of evolution, from *S. cerevisiae* to mammals, and that it applies to both of the major isoforms of mammalian cofilin (Cofilin-1 and ADF). These findings establish a new paradigm, in which a filament end-binding protein and a filament side-binding protein work in concert to control actin dynamics, and explain how rapid actin depolymerization might be achieved in vivo.

P90/B103

Actin-membrane Detachment Is the Initiator of Polymerization-driven Protrusion.

E. Welf[1], C. Miles[2], J. Huh[1], M. Driscoll[1], T. Isogai[1], J. Noh[1], A. Weems[1], J. Chi[1], T. Pohlkamp[1], K. Dean[1], R. Fiolka[1], A. Mogilner[1], G. Danuser[1]; [1]UT Southwestern Medical Center, Dallas, TX, [2]New York University, New York, NY.

Actin polymerization generates cell protrusions by exerting force on the inner leaflet of the cell membrane. This occurs without the aid of molecular motors and is thought to involve “ratcheting” of the cell membrane via insertion of actin monomers between the f-actin network and the membrane. This process is aided by the arp2/3 complex, which nucleates filament branches from existing filaments, but requires membrane tethering of arp2/3 through the WASP/WAVE family of proteins. Thus arp2/3 functions both as an actin nucleating factor and as an actin-membrane linker that opposes monomer addition. The tethered Brownian ratchet model explains how a balance between tethered and free actin

monomers generates force during steady state protrusion, but cannot explain protrusion onset. Through a combination of experiments, computational analysis, and theoretical modeling, we show that local depletion of membrane cortex links that are distinct from those of WASP/WAVE initiates protrusion. Using live cell microscopy and time series analysis to measure thousands of protrusion events, we found that the membrane-cortex linker ezrin is depleted prior to protrusion onset and before enrichment of arp2/3. We also found that arp2/3 operates independently from ezrin depletion to drive protrusion, confirming that parallel, but independent mechanisms drive protrusion. Incorporating this information into a theoretical model for how actin polymerization generates protrusion, we found that small fluctuations in ezrin localization, but not actin, were sufficient to initiate protrusion. Model simulations also predicted that increases in ezrin affinity reduce protrusion frequency, duration, and velocity. Our experiments with ezrin mutants with such elevated affinity for actin confirmed these predictions. Altogether, our results demonstrate the requirements for different types of membrane cortex detachment during protrusion, enabling us to synthesize a more comprehensive model for how actin-driven protrusion generates force. Given that actin-membrane detachment is a critical regulatory factor in protrusions that do not require actin-generated force, our findings raise the intriguing possibility that morphologically different protrusions may be initiated by a common set of processes.

Non-muscle Myosin IIc Tunes Actin Bundle Length in Microvilli.

C. R. Chinowsky, M. J. Tyska; Vanderbilt University, Nashville, TN.

Transporting epithelial cells are covered in apical microvilli, which help to form a barrier between luminal contents and the cell. Microvilli are critical for maintaining cellular homeostasis, yet little is known about the mechanisms that control the morphology of these protrusions. The intestinal enterocyte is covered in densely packed microvilli, known as the brush border. Each protrusion contains a bundle of 20-30 actin filaments, with the barbed ends located at the distal tips, and the pointed ends anchored in a region of the cell known as the terminal web. Little is known about how the terminal web contributes to microvillar organization, morphology and maintenance. Within the terminal web, there are a variety of proteins, including non-muscle myosin II (NMII), a conventional myosin motor expressed in all eukaryotic cells. Within the human intestine, three different heavy chains of NMII are expressed; A, B and C, with NMII-A and NMII-C dominating expression in enterocytes. Here, we provide evidence that NMII-C forms a novel network across the enterocyte apical domain at the level of the terminal web. Line scans along the microvillar axis show that NMII-C is enriched near the pointed-ends of microvillar actin bundles. Our experiments reveal that altering the force production of NMII-C via genetic or pharmacological perturbations alters microvillar morphology. These findings suggest that NMII-C helps to regulate microvillar dimensions via the pointed end.

P102/B105

Non-muscle Myosin II Is Essential for the Negative Regulation of B Cell Receptor Signaling and B Cell Activation.

M. Seeley-Fallen[1], M. Lazzaro[1], C. Liu[2], A. Upadhyaya[1], W. Song[1]; [1]University of Maryland, College Park, College Park, MD, [2]University of Maryland, College Park, MD.

B cells mediate humoral immunity and generate antibody responses against antigenic challenge. While positive signaling mediated through B cell receptors (BCR) is required for the initiation of B cell activation, prolonged or uncontrolled BCR signaling is associated with the rise of self-reactive B cells and the subsequent development of autoimmune diseases. We previously demonstrated a role for the actin cytoskeleton in the negative regulation of B cell signaling by driving B cell contraction after spreading on antigen-presenting surfaces, leading to the formation of BCR central clusters. Non-muscle myosin II (NMII) is an actin motor-protein that is expressed in B cells and known to be involved in B-cell migration, cytokinesis, and extraction of antigen (Ag) from antigen-presenting cells. This study reveals that NMII-mediated actin contraction negatively regulates BCR signaling using both NMII inhibitors and conditional knockout mice (NMIIA KO). Upon BCR binding of antigen, NMIIA is recruited to the spreading surface of B cells in contact with antigen-presenting surfaces and forms a ring-like structure upon B cell contraction. B-cell contraction and formation of BCR central clusters are delayed in both NMIIA KO B cells and blebbistatin-treated B cells. NMIIA KO and blebbistatin-treated B cells show up-regulation of BCR signaling, including tyrosine, CD79a, BLNK, and Erk phosphorylation when compared to control B cells. In contrast, the level of phosphorylated SH2-containing inositol 5-phosphatase (SHIP-1), an inhibitory signaling molecule, is reduced. Associated with this enhanced signaling, NMIIA KO results in increased numbers of spontaneously activated germinal center B cells when compared to control mice. Serum levels of Ag-specific IgG in response to immunization with a T-dependent antigen and binding affinity of IgG to the immunization antigen are reduced, while total serum levels of IgG are elevated in NMIIA KO mice compared to control mice. Furthermore, NMIIA KO mice displayed a reduced number of Ag-specific memory B cells compared to control mice. Together, our results reveal NMIIA exerts a B-cell-intrinsic inhibition on B-cell activation by promoting B cell membrane contraction, and coalescence of BCR microclusters into central clusters, revealing a novel mechanistic link between actin remodeling and negative regulation of signaling.

P103/B106

Nonmuscle Myosin 2 Regulates Cortical Stability of Vascular Sprouts during Blood Vessel Formation.

X. Ma, Y. Mukouyama, R. Adelstein; National Heart, Lung, and Blood Institute, NIH, Bethesda, MD.

Nonmuscle myosin 2 (NM2) plays important roles in regulating various basic cellular functions such as cell migration, cell adhesion and cell division. Three paralogs of NM2, namely NM2A, 2B and 2C, are expressed in mammals including mice and humans. Both NM 2A and 2B, but not 2C are essential for mice to thrive from embryonic development. To study the role of NM2 in blood vessel formation we ablated NM2 specifically in endothelial cells in mice. We find that NM2A plays a major role in regulating blood vessel formation. Ablation of NM2A results in a defect in back skin blood vessel formation with reduced blood vessel coverage and increased branching morphogenesis, while ablation of NM2B shows no obvious abnormalities. However mice with NM2B ablated together with one copy of NM2A show defects in blood vessel formation and mice with NM2A ablated together with one copy of 2B show more severe defects in blood vessel formation. Moreover homozygous mice expressing a motor-impaired

R709C-NM2B also show defects in blood vessel formation. Since NM2C is not detected in endothelial cells, these results suggest that both NM2A and 2B are involved in regulating blood vessel formation and that the mutant NM2B can interfere with normal NM2A function during blood vessel formation. In vitro vascular sprouting assays from the embryonic body (EB) shows that ablation of NM2A but not 2B results in excessive vascular sprouting. Live cell imaging of EB sprouting further reveals that the endothelial sprouts of the wild-type EB migrate persistently with numerous dynamic membrane blebs. Ablation of NM2A results in constant turning and branching of the sprouts. Moreover NM2A ablated sprouts show no obvious blebbing activity, but form large membrane protrusions indicating a loss of membrane stability. Live imaging of EGFP-NM2A EB sprouting further shows that NM2A is enriched during retraction of blebbing. We thus propose that NM2 regulates blood vessel formation by stabilizing the cortical membrane of vascular sprouts. We further show that ROCK is the major kinase which activates NM2 in vascular sprouting, since the sprouting defect occurs with inhibition of NM2 activity by blebbistatin or the ROCK inhibitor (Y27632), but not with the MLCK inhibitor (ML-7).

NM2A Deletion Promotes Cancer through Chromosomal Instability.

A. Liu[1], O. H. Richmond, III[1], T. Wei[1], A. Zhovmer[1], C. Liu[1], C. Van Waes[2], X. Ma[1], R. S. Adelstein[1]; [1]National Heart, Lung, and Blood Institute, Bethesda, MD, [2]National Institute on Deafness and Other Communication Disorders, Bethesda, MD.

Chromosomal instability (CIN) underpins tumor cell initiation and propagation. In human cancers, CIN correlates positively with poor patient prognosis. Recent studies implicate non-muscle myosin 2A (NM2A) for its role in cancer. Previously, our lab reported development of squamous cell carcinoma in the tongue epithelia of a murine model upon loss of NM2A. Here, we propose that NM2A functions as a tumor suppressor and loss of NM2A promotes genomic instability, aberrant growth, and dysregulated migration, leading to tumorigenesis. To investigate our hypothesis, the mitosis of human squamous cell carcinoma cells (UMSCC110) was characterized. UMSCC110 cells (a cell line developed at the Univ. Of Michigan) contain a preexisting mutation in both alleles of *Myh9* causing early termination of mRNA. The mutant NM2A null cells were transfected with a GFP-NM2A construct (lentiviral) to generate NM2A rescued cells. In these cells, histone H2B was labeled using red fluorescent protein (H2B-RFP-NM2A null and H2B-RFP-NM2A rescued cells) for visualization of mitotic events. In *vitro* analyses of cell models reveal differential rates of migration and growth regulated by NM2A. Live cell fluorescence imaging of cells undergoing mitosis were deconvoluted using Huygens Essential to visualize mitotic abnormalities such as anaphase bridging and lagging chromosomes. Time courses of mitosis between NM2A null (n=18) and NM2A rescued (n=17) cells were highly statistically different after two-way ANOVA analysis ($p < 0.0001$). On average, rescued cells completed mitosis more readily, with half lives of 102.6 ± 44 seconds compared to NM2A null cells with 82.20 ± 28.53 seconds. Similar levels of bridging chromosomes were detected in the NM2A null (8/18) compared to the NM2A rescued (7/17), however lagging chromosomes were observed only in NM2A null (7/18) but not in NM2A rescued (0/17) cells. An aphase lagging chromosomes are a primary chromosome segregation defect in tumors and their presence is indicative of underlying defects which cause chromosomal instability. Taken together, our data suggests NM2A functions as a tumor suppressor and loss of NM2A enables hallmarks of cancer.

P105/B108

Disrupted Mechanobiology Links the Molecular and Cellular Phenotypes in Familial Dilated Cardiomyopathy.

S. R. Clippinger, P. E. Cloonan, L. Greenberg, M. Ernst, W. T. Stump, **M. J. Greenberg**; Washington University, St. Louis, MO.

Familial dilated cardiomyopathy (DCM) is a leading cause of sudden cardiac death and a major indicator for heart transplant. Familial DCM is frequently caused by mutations of cardiac sarcomeric proteins; however, connecting mutation-induced changes in sarcomeric protein function with the phenotype seen in cardiomyocytes is still a challenge for the field. Many of the changes in contractility at the molecular scale caused by sarcomeric DCM mutations are subtle, begging the question of what other factors could link molecular-scale changes with the cellular phenotype. We hypothesized that DCM-causing mutations of sarcomeric proteins affect not only sarcomeric contraction, but also how cardiomyocytes sense and respond to mechanobiological changes associated with aging and disease. To test this hypothesis, we studied the molecular and cellular consequences of a DCM mutation in troponin-T, ΔK210. Using biophysical and biochemical tools, we determined the molecular mechanism of ΔK210, and then we used computational modeling to predict that the mutation should reduce the force per sarcomere in cardiomyocytes. We used CRISPR/Cas9 to generate mutant human induced pluripotent stem cell derived cardiomyocytes (hiPSC-CMs). We found that ΔK210 not only reduces the force per sarcomere in hiPSC-CMs, but it also causes cellular hypertrophy and impairs the ability of hiPSC-CMs to adapt to changes in substrate stiffness (e.g., myocardial fibrosis that occurs with aging and disease). These results link the molecular and cellular phenotypes and they implicate impaired mechanosensing by cardiomyocytes as an under-appreciated mechanism in the pathogenesis and progression of DCM caused by sarcomeric proteins. These results also have important implications for our understanding of cardiac disease and the design of precision therapeutics.

P106/B109

Altering the Backbone: a Mechanism for How Flightin-myosin Interaction Impacts Structure and Mechanics of Muscle Thick Filaments.

L. Menard, N. Wood, J. Vigoreaux; University of Vermont, Burlington, VT.

Myosin II light meromyosin (LMM)-binding proteins potentially modulate thick filament structural and mechanical properties and influence muscle function. In *Drosophila* indirect flight muscles (IFM), flightin augments flexural rigidity of thick filaments, is necessary for the establishment of their in *vivo* length and for maintaining their structural integrity in active muscle. Flightin is defined by WYR, a ~52 amino acid domain conserved in hexapods and crustaceans. Loss of muscle function observed in *Drosophila* mutants lacking flightin is partially restored by truncated flightin missing either the N- or C-terminal domains flanking WYR and implicate WYR as essential for flightin function. In this study, we use circular dichroism to characterize the secondary structure of WYR and to uncover structural changes upon its complexing with LMM. Resultant ellipticity at 260-190nm reveals a structural profile for WYR and supports an interaction with the LMM that coordinates a conformational shift in both binding partners. The secondary structure of WYR is concentration and ionic strength dependent and displays predominant negative ellipticity at ~192nm with a 222/208 ratio of ~0.38, a trademark of a 3_{10} helix. WYR is found to be 40-50% unstructured with predominant beta character. WYR in the context of the LMM shows substantial conformation shifts including an increase in the 222/208 ratio. While the LMM

alone exhibits a 222/208 ratio of ~1.1, the LMM in the context of WYR exhibits a greater 222/208 ratio and is sedimented out of solution, maximally at 5:1. The increased 222/208 ratio is due to decreased intensity of the 208 minima, indicating increased coiled-coil content. Our results support the hypothesis that WYR binds the LMM and that this interaction brings about structural changes in the coiled-coil. LMM sedimentation by WYR suggests a possible mechanism by which flightin influences thick filament assembly in *vivo*. Furthermore, the distinct shifts in LMM secondary structure observed in the presence of WYR provide molecular insight into the role of flightin in defining the viscoelastic properties of the thick filament that influence muscle fiber mechanical output. Our results are further substantiated by high resolution cryo EM studies of IFM thick filaments that show the association of a non-myosin density with unwound portions of the myosin dimers in the filament backbone.

P107/B110

The Replacement of Myosin Molecules in Thick Filaments Is Different between Slow- and Fast-twitch Myofibers.

M. Kigaki[1], K. Ojima[2], T. Suzuki[1], K. Kobayashi[1], T. Nishimura[1]; [1]Cell and Tissue Biology Laboratory, Graduate School of Agriculture, Hokkaido University, Sapporo, JAPAN, [2]Animal Products Research Division, Institute of Livestock and Grassland Science, NARO, Tsukuba, JAPAN.

Myosin, one of the myofiber-type markers, is a major myofibrillar component in skeletal muscles. Approximately 300 myosin molecules were assembled into a bipolar thick filament in the sarcomere. Our previous cell culture studies demonstrated that myosin molecules are vigorously exchangeable in thick filaments of myotubes, and that myosin replacement rate is modulated by myosin content in cytosol as well as heat shock protein (Hsp) 90 activity (Ojima K. et al., 2015, 2017, 2018). However, the effects of myofiber-types on myosin replacement remain unclear. In this study, we investigated the impact of myofiber-types on myosin replacement rate in isolated single myofibers. To examine this, we generated two types of fluorescence protein knock-in mice. One was GFP-Myh7 knock-in mouse expressing GFP-fused slow Myh7 (GFP-Myh7) instead of wild type Myh7. The other was KusabiraOrange-Myh1 knock-in mouse expressing KusabiraOrange-fused fast Myh1 (KusabiraOrange-Myh1) instead of wild type Myh1. In these mice, the expressed GFP-Myh7 and KusabiraOrange-Myh1 were precisely incorporated into the A-band of the sarcomeres. To measure the replacement rate of GFP-Myh7 in slow-twitch myofibers or KusabiraOrange-Myh1 in fast-twitch myofibers, fluorescence recovery after photobleaching (FRAP) technique was used. The fluorescence recovery degree in slow-twitch myofibers was higher than that in fast-twitch myofibers. The replacement rate of myosin molecules in fast-twitch myofibers was fast compared to that in slow-twitch myofibers. Next, treatment with inhibitors of protein synthesis or Hsp90 activity significantly reduced the fluorescence recovery degrees of myosin in both slow- and fast-twitch myofibers as compared to the control group. The inhibition ratios of fluorescence recovery were higher in slow-twitch myofibers than that in fast-twitch myofibers. Interestingly, the fluorescence recovery degree of slow-twitch myofibers treated with MG132, a proteasome inhibitor, was significantly lower than the control group, although that of fast-twitch myofibers was not affected. Taken together, our results suggest that the replacement of myosin molecules in thick filaments is different between slow- and fast-twitch myofibers due to the difference of myosin synthesis, Hsp90 and proteasome activity between them.

P108/B111

A Novel Isoform of Myosin 18A (Myo18Aγ) Is a Critical Component of Cardiac Sarcomeres.

M. Horsthemke[1], L. M. J. Nutter[2], A. C. Bachg[1], B. V. Skryabin[3], U. Honnert[1], T. Zobel[4], S. Bogdan[5], M. Stoll[6], M. D. Seidl[7], F. U. Müller[7], U. Ravens[8], A. Unger[9], W. A. Linke[9], P. R. R. van Gorp[10], A. A. F. de Vries[1], M. Bähler[1], **P. Hanley**[1]; [1]Institut für Molekulare Zellbiologie, Münster, GERMANY, [2]The Hospital for Sick Children, Toronto, ON, CANADA, [3]Department of Medicine, Münster, GERMANY, [4]Heinrich Heine Universität Düsseldorf, Düsseldorf, GERMANY, [5]Institut für Physiologie und Pathophysiologie, Marburg, GERMANY, [6]Institut für Humangenetik, Münster, GERMANY, [7]Institut für Pharmakologie und Toxikologie, Münster, GERMANY, [8]Institut für Experimentelle Kardiovaskuläre Medizin, Freiburg, GERMANY, [9]Institut für Physiologie II, Münster, GERMANY, [10]Laboratory of Experimental Cardiology, Leiden, NETHERLANDS.

Two isoforms of myosin 18A (Myo18A), Myo18Aα and Myo18Aβ, are well known. Myo18Aα is widely expressed, whereas Myo18Aβ, which lacks the unique N-terminal extension of Myo18Aα, is predominantly expressed in hematopoietic cells. To elucidate the physiological functions of Myo18A we studied various *Myo18a* knockout mouse models. Homozygous deletion (homozygous tm1a, tm1b or tm1d alleles) in mouse was embryonic lethal at around embryonic day 11.5 (E11.5). Surprisingly, *Myo18a* was predominantly expressed in the embryo heart, and conditional deletion of *Myo18a* in cardiac myocytes was embryonic lethal. Neither Myo18Aα nor Myo18Aβ protein could be detected by Western blot in mouse heart using an antibody directed against the extreme C-terminus, whereas a larger than expected protein could be detected using alternative anti-Myo18A antibodies. Indeed, RNA-Seq analysis revealed that a novel Myo18A transcript is expressed in mouse ventricular myocytes, as well as in human heart. Cloning and sequencing confirmed that the cardiac isoform, termed Myo18Aγ, lacks the PDZ-containing N-terminus characteristic of Myo18Aα and incorporates alternative N- and C-termini. EGFP-tagged Myo18Aγ localized to the A-bands of sarcomeres in transfected ventricular myocytes. Furthermore, electron microscopy revealed highly disorganized sarcomeres in the hearts of *Myo18a*-deficient E10.5 embryos. In conclusion, we have identified a novel isoform of Myo18A (Myo18Aγ) which is important for cardiac sarcomere assembly and/or maintenance. Hence, both members of class XVIII myosins, Myo18A and Myo18B, are essential components of cardiac sarcomeres.

P109/B112

Aha1, a Hsp90 Co-chaperone, Is Dispensable for Hsp90a1 Function in Sarcomere Organization during Muscle Development.

S. Du, H. Xiao; University of Maryland, Baltimore, MD.

Heat shock protein 90s (Hsp90s) are molecular chaperones that play critical roles in protein folding, maturation and function. Our previous studies demonstrated that Hsp90a1 is essential for muscle development. Loss of *hsp90a1* resulted in myosin protein degradation and defective sarcomere organization in skeletal muscle of zebrafish embryos, leading to early larval lethality around 5 dpf. Hsp90s is a dimeric molecular chaperone that function in an ATP-dependent client activation cycle. The most potent stimulator of the Hsp90 ATPase activity is Aha1, a co-chaperone that binds to the Hsp90 middle domain and exerts stimulatory effect on Hsp90 ATPase activity. To determine the expression and function of Aha1 in the Hsp90 ATPase activation cycle to control the assembly of a large group of client proteins into a complex sarcomere structure in muscle cells of zebrafish embryos under normal and stress conditions. Zebrafish genome contains two *aha1* genes, namely *aha1a* and *aha1b*. We showed that under normal physiological condition, *aha1a* was predominantly expressed in heart and skeletal

muscles of the zebrafish embryo, whereas *aha1b* showed a weak expression mainly in the head region. However, under stress conditions from higher temperature incubation or *hsp90a1* knockdown, we found that both *aha1a and aha1b* expression was dramatically increased. While high temperature induced a broad upregulation of *aha1a and aha1b in* the entire embryo, knockdown of *hsp90a1*, but not *hsp90a2* upregulated *aha1a and aha1b* expression specifically in skeletal muscles. This muscle-specific upregulation was also observed in the *smyd1* mutant embryos that have disrupted sarcomere organization. To investigate whether Aha1a and Aha1b are involved in muscle development, we knocked out both genes by CRISPR in zebrafish. Loss of Aha1a or Aha1b alone had no effect on muscle development and fish survival. The expression of *hsp90a1* and *hsp90a2* was normal in both mutant embryos. However, *aha1a* expression was significantly upregulated in Aha1b mutant embryos, suggesting a compensatory response and possible functional redundancy. To completely abolish Aha1 function, we generated the *aha1a;aha1b* double mutants. The sarcomere organization revealed by anti-myosin and phalloidin staining appeared normal in the double mutant embryos, suggesting that Aha1a and Aha1b are dispensable for Hsp90a1 function in sarcomere organization under normal conditions. Future studies will be focused on characterizing the long-term effect of *aha1a;aha1b* double mutation in stress conditions from high temperature or in Hsp90a1 or Smyd1 heterozygous mutant background to assess haploinsufficiency.

Cardiomyocytes Seen as Active Matter: Heterogeneities and Collective Dynamic Instabilities in Sarcomere Contractions.

D. Haertter[1,2], W. Zimmermann[3], C. F. Schmidt[1]; [1]Department of Physics and Soft Matter Center, Duke University, Durham, NC, [2]Third Institute of Physics-Biophysics, University of Göttingen, Göttingen, GERMANY, [3]Institute for Pharmacology, University of Göttingen Medical School, Göttingen, GERMANY.

Cardiac muscle contraction involves highly coordinated dynamics, from the level of the myosin motors on the length-scale of nanometers to that of the whole organ on the scale of centimeters. The molecular dynamics of myosin motors and the macroscopic motion of whole muscles are well studied. Many features of muscle contraction that are not well understood, however, emerge on the mesoscopic length scale of (half-)sarcomeres, the basic contractile units of muscles consisting of around 300 mechanically coupled myosin molecular motors. Basic theories of collective molecular motor dynamics predict emergent phenomena such as dynamic instabilities and spontaneous oscillatory motion due to non-monotonic force-velocity relations. On the next level of the hierarchy, when half-sarcomeres are coupled in series and in parallel, even richer emergent dynamics are expected. We have imaged sarcomere dynamics in individual stem-cell-derived cardiomyocytes with endogenous fluorescent labeling of z-lines introduced by CRISPR/Cas9, and have observed that mechanical competition leads to sarcomere de-coherence and complex dynamic heterogeneity. We model the observed phenomena with a dynamic myofibril model of multiple force-generating elements with non-monotonic force-velocity relations from a complex systems / active matter perspective.

Optimized Filopodia Formation Requires Myosin Tail Domain Cooperation.

A. L. Arthur[1], L. D. Songster[1], H. Sirkia[2], C. Kikuti[2], A. Houdusse[2], **M. A. Titus**[1]; [1]University of Minnesota, Minneapolis, MN, [2]Institut Curie, Paris, FRANCE.

Filopodia are actin-filled protrusions employed by cells to interact with their environment. Filopodia formation in Amoebozoa and Metazoa requires the phylogenetically diverse MyTH4-FERM (MF) myosins DdMyo7 and Myo10, respectively. While Myo10 functions as an antiparallel dimer, DdMyo7 lacks a coiled-coil domain in its N-terminal tail region, called the proximal lever arm (PLA), raising the question of how such divergent motors perform similar functions. A series of DdMyo7 deletion mutants were tested for their ability to target to the cortex and rescue filopodia formation in the *myo7*null mutant. The tail domain consists of the PLA and two MyTH-FERM (MF) domains separated by an SH3 domain. Deletion of the PLA or the C-terminal MyTH-FERM (MF2) domain does not impact filopodia formation, however, deletion of both together does, revealing that the DdMyo7 PLA works in cooperation with the C-terminal MF domain to promote filopodia formation. An alytical ultracentrifugation studies showed that the proximal tail can dimerize, albeit weakly. The results suggest that DdMyo7 function requires partner-mediated dimerization, where an MF2 binding partner brings two myosins together at the cortex, enabling interactions between them and formation of a stable dimer. Cortical targeting of DdMyo7 is required for filopodia initiation and is controlled by head-tail autoinhibition. Interestingly, the SAH and N-terminal region of the PLA are needed to regulate the motor's autoinhibition, possibly by facilitating the proper conformation of the inactive state. The PLA is thus proposed to allow for sensitive regulation of myosin activity by preventing inappropriate activation of filopodia formation. Several Metazoan MF myosins, such as Myo7A and Myo15, also lack clear dimerization sequences but there is evidence that they are dimerized by partner binding, suggesting that this is an ancient and conserved mode of regulating MF myosin function. The results reveal that the basic principles of MF myosin-based filopodia formation are conserved but that the filopodial myosins DdMyo7 and Myo10 employ divergent mechanisms for dimerization. Relgulatory Light Chain Orientaiton on Skeletal Myosin Using a Bifunctional Spin Label.

Y. Savich, M. R. McCarthy, D. D. Thomas; University of Minnesota, Twin Cities, Minneapolis, MN.

We performed electron paramagnetic resonance (EPR) on skeletal myosin, labeling the regulatory light chain (RLC) with a bifunctional spin label (BSL). To achieve stereoselective site-directed labeling with BSL, we engineered a pair of cysteines (i, i+4) in RLC. By exchanging BSL-labeled RLC onto myosin head (S1)/heavy meromyosin (HMM) and decorating oriented muscle fibers with BSL-RLC-S1/BSL-RLC-HMM, we obtained EPR spectra from which the angular distribution of BSL can be determined with high resolution relative to the muscle fiber axis. In our previous work (Savich et al., JGP, 2019), we exchanged BSL-RLC on intact myosin in skinned muscle fibers and observed substantial angular disorder, which varied with the RLC labeling site. In the absence of ATP (rigor), each of the two labeled helices exhibited both ordered (angular dispersion ~ 9-11 degrees) and disordered (angular dispersion > 38 degrees) populations. Using these angles to determine the orientation of the lever arm (light chain domain combined with converter subdomain), we observed that the oriented population corresponds to a lever arm that is perpendicular to the muscle fiber axis, and that addition of ATP in the absence of Ca^{2+}

(inducing relaxation) shifts the orientation to a disordered distribution. Similar orientation was observed on BSL-RLC-S1-fiber, BSL-RLC-HMM-fiber for probes located on the E helix. However, orientation of the B helix becomes completely disordered in both fragments. Addition of ATP releases decorated myosin, showing the ATP dependence of actin binding is not perturbed by labeling. Activity of labeled S1 was verified by the actin-activated NADH ATPase assay. We conclude that the lack of uniform orientation in labeled RLC, observed previously in muscle fibers by both EPR and fluorescence, is due to strain between two myosin heads. This work was supported by NIH R01AR032961 and R37AG26160 to DDT. YS was supported by NIH T32AG29796 and a University of Minnesota Interdisciplinary Doctoral Fellowship.

Regulation of Filamentous Actin Structural Dynamics by Myosin XV in Mechanosensory Stereocilia.

R. Gong[1], A. Shams[2], F. Jiang[3], M. Reynolds[1], S. Espinosa[1], P. Gurel[1], Y. Takagi[4], J. Sellers[4], T. B. Friedman[2], J. Bird[3], G. Alushin[1]; [1]The Rockefeller University, New York, NY, [2]National Institute of Deafness and Other Communication Disorders, Bethesda, MD, [3]University of Florida, Gainesville, FL, [4]National Heart, Lung and Blood Institute, Bethesda, MD.

Unconventional myosin XV (myoXV) is an actin-based motor that is essential for mechanosensory stereocilia development. MyoXV has been shown to localize to the tips of actin-based stereocilia to promote their elongation. Some mutations of *Myo15* abolish stereocilia elongation and cause deafness. However, the mechanism by which myoXV regulates stereocilia architecture remains elusive. Here, we present cryo-EM reconstructions of the wild-type and disease-causing D1647G mutant actomyosin complexes and bare filamentous actin (F-actin) at 2.75, 3.65, and 2.73Å resolution, respectively. Comparison of the wild-type actomyosin complex to F-actin alone reveals that myoXV induces apparent local structural changes at the interface. These structural changes are propagated and induce a global rearrangement of the actin subunit, which leads to a 0.2 Å reduction in the helical rise. In our naked F-actin structure, residues G47 and Q48 of the D-loop, which mediates inter-subunit contacts, are structurally flexible. Upon myoXV binding, the D-loop is partially stabilized and samples two conformations. However, the D-loop of the D1647G mutant actomyosin is completely stabilized in a single conformation. Moreover, we find that wild-type myoXV promotes, whereas the D1647G mutant inhibits, actin polymerization in *vitro*, possibly through differential modulation of the D-loop. Our results suggest myoXV could control stereocilia length by regulating F-actin structural plasticity required for accelerated actin polymerization during stereocilia elongation.

P114/B117

Unconventional Mechanisms of Actin Polymerization Drive Stereocilia Elongation in the Cochlea.

M. Barzik[1], F. Jiang[2], R. Gong[3], C. Aguilar[4], A. Shams[1], S. Espinoza[3], M. Reynolds[3], J. Werth[1], C. Faaborg-Andersen[1], R. Harley[1], D. Sutton[1], A. Parker[4], Y. Takagi[5], J. R. Sellers[5], S. D. Brown[4], T. B. Friedman[1], G. M. Alushin[3], M. R. Bowl[4], **J. E. Bird**[2]; [1]NIDCD, Bethesda, MD, [2]University of Florida, Gainesville, FL, [3]Rockefeller University, New York City, NY, [4]MRC Harwell Institute, Harwell, UNITED KINGDOM, [5]NHLBI, Bethesda, MD.

Stereocilia are actin-based organelles that project from the apical surface of inner ear hair cells. Each hair cell assembles hundreds of stereocilia and precisely arranges them into ranks of increasing height to create a mechanosensitive hair bundle that detects sound. A para-crystalline actin core sets the architecture and mechanical strength of each stereocilium, yet how actin polymerization /

depolymerization is coordinated within these organelles remains poorly understood. An essential molecular component in the assembly mechanism is unconventional myosin 15a (MYO15A) which is necessary for establishing the height of individual stereocilia and architecture of the overall hair bundle. MYO15A is hypothesized to traffic an 'elongation complex' of proteins (WHRN, EPS8, GNAI3 and GPSM2) to the stereocilia tips; the major site of actin polymerization during elongation. How MYO15A and the elongation complex proteins collectively regulate actin polymerization is unknown. Here, we describe a missense mutation (p.D1647G) in the MYO15A ATPase (motor) domain that interferes with stereocilia growth and causes hearing loss in a mutant mouse model. Unlike previous mouse models, where molecular trafficking of MYO15A and the elongation complex were completely disrupted, MYO15A and the elongation complex were still trafficked to the stereocilia tips of p.D1647G hair cells. These data indicate that trafficking of the MYO15A-elongation complex is not sufficient for stereocilia elongation, and alludes to MYO15A having an additional function at the stereocilia tip. We hypothesized that the MYO15A ATPase domain might directly regulate actin polymerization. To test this, we purified both wild-type and p.D1647G MYO15A and studied their activity and structures bound to F-actin. Using single-particle cryo-electron microscopy, we identified structural plasticity within the actin DNAase I-binding loop ('D-loop'), that is maintained in the presence of wild type MYO15A, but suppressed by the p.D1647G mutant. To test the functional impact of this plasticity, we measured the activity of purified MYO15A using the in *vitro* pyrene-actin polymerization assay. Wild-type MYO15A strongly stimulated actin polymerization, whereas the p.D1647G MYO15A had minimal effects on polymerization kinetics. We infer that the stimulation effect by wild-type MYO15A originates from stabilizing actin-actin contacts whilst maintaining the structural plasticity required for polymerization. Our results support a new model for stereocilia growth, where MYO15A traffics proteins essential for elongation, but also directly stimulates actin polymerization at the stereocilia tip to control hair bundle architecture.

P115/B118

Src Kinases Modulate Myosin 2 Assembly.

A. Cuevas, H. Wu, **J. R. Beach**; Loyola University Chicago Medicine, Maywood, IL.

With actin, myosin 2 is the major driver of cell contractility. It remains indisputable that phosphorylation of the regulatory light chain at Thr18/Ser19 activates myosin 2 to induce contraction. Since it was identified in the 1980's, RLC phosphorylation has justifiably received the bulk of the attention. However, if contraction is essential throughout cell biology, and myosin 2 activity is determinant for contraction, then a model in which myosin 2 activity is largely controlled by a single mechanism should be met with skepticism. It is logical that additional mechanisms control myosin 2. Moreover, contractile events are not an on/off switch. They must be tuned to fit the cellular process: too little contractility will result in process failure; too much can literally rip cells and tissues to pieces. Therefore, cells must "sense" levels of contractility and have a mechanism to tune it. The field has described many pathways that cells use to increase contractility. We lack analogous mechanistic insight for how cells reduce or tune the level of contractility. High throughput mass spectrometry data suggests robust phosphorylation of myosin 2A at Tyr1408. This residue is in the middle of the coiled-coil tail domain, suggesting it might be important in regulating myosin 2 assembly dynamics. To explore this at the cellular level, we generated a phospho-specific antibody and an EGFP-tagged phosphoblocking mutant (myosin 2A-Y1408F). Using this antibody, we demonstrate that Tyr1408 is dynamically phosphorylated in cells. Multiple assays demonstrate expression of the phosphoblocking mutant results in severe overassembly of myosin 2 filaments. By performing an in vitro kinase screen with 42 ubiquitous or semi-ubiquitous tyrosine kinases, we observe

Tyr1408 phosphorylation by Src family kinases, including Yes1, FynA, and Src. Consistently, treatment of cells with Src inhibitors decreases myosin 2-Tyr1408 phosphorylation levels. Growth factor and adhesion signaling activate both Src kinases and myosin 2 assembly. Our data suggest a more complex model and potential negative feedback loop mediated by direct Src phosphorylation of myosin 2.

Morn4 Influences the Length and Dynamics of Myo3a-Associated Actin Protrusions.

L. Gunther[1], S. Nelson[2], J. Cirilo[1], R. Cui[3], R. Desetty[1], B. Kachar[3], D. Warshaw[2], C. Yengo[1]; [1]Penn State University College of Medicine, Hershey, PA, [2]University of Vermont, Burlington, VT, [3]National Institute of Health, Bethesda, MD.

Myo3A localizes to the tips of inner ear hair cell stereocilia and plays a role in regulating stereocilia length and morphology. In addition, mutations in Myo3A are associated with non-syndromic deafness and lack of functional Myo3A causes accelerated age-dependent stereocilia degeneration. Previously we discovered that Myo3A binds a protein with four membrane occupation nexus motifs, MORN4, and the two proteins can co-localize at the tips of filopodia. In the current study, we demonstrate that MORN4 localizes to the tips of inner ear hair cell stereocilia which overlaps with the site of Myo3A localization. The presence of MORN4 enhances Myo3A localization to the tips of filopodia and increases the lengths of Myo3A-associated filopodia in COS7 cells. In addition, MORN4 alters the dynamics of Myo3A-associated filopodia by increasing the filopodia extension rate 30% without altering filopodia retraction. We investigated the dynamics of GFP-tagged Myo3A in COS7 cell filopodia in the presence and absence of MORN4 using FRAP. The half-time of Myo3A recovery at the filopodia tips is about 4-fold slower in the presence of MORN4. We found that GFP-tagged Myo3A co-expressed with MORN4 can co-localize with liposomes in vitro and cell fractionation experiments suggest Myo3A is associated with the plasma membrane. Myo3A containing the motor domain and full length tail domain can generate actin filament sliding when its tail is docked onto a motility surface using an antibody specific for MORN4 or the C-terminal tail homology domain II motif. Overall, our results suggest a model in which Myo3A generates a tip-directed force in actin protrusions and that MORN4 enhances extension and length by increasing the number of tip localized Myo3A motors.

Regulation of Non-muscle Myosin II Assembly by the Actin Cytoskeleton.

W. Chou[1,2], D. R. Kovar[3,4], M. L. Gardel[2,5,6]; [1]Graduate Program in Biophysical Sciences, University of Chicago, Chicago, IL, [2]Institute for Biophysical Dynamics, University of Chicago, Chicago, IL, [3]Department of Molecular Genetics and Cell Biology, University of Chicago, Chicago, IL, [4]Department of Biochemistry and Molecular Biology, University of Chicago, Chicago, IL, [5]Department of physics, University of Chicago, Chicago, IL, [6]James Franck Institute, Chicago, IL.

Non-muscle myosin II (NMII) drives dynamic cellular processes, including cell migration, cytokinesis, and tissue morphogenesis. Upon regulatory light chain (RLC) phosphorylation, NMII self-assembles into bipolar filaments, which serve as the functional unit to slide and translocate on actin filaments to contract the F-actin network. F-actin networks in cells adopt two major architectures: linear actin filaments nucleated by formin and branched F-actin nucleated by Arp2/3. In this work, we aim to understand whether NMII assembly is regulated by different F-actin architectures. Using the fibroblast cell line 3T3 as a model system, we disassembled NMII filaments by a ROCK inhibitor Y-27632 and

subsequently washed out the drug to allow NMII filaments to reassemble. During the washout experiments, cells are treated with pharmacological inhibitors of formin or Arp2/3. The treated cells are then fixed, immunostained for NMIIA and imaged with confocal microscopy. We find that formin inhibition by SMIFH2 in conjunction with Y-27632 washout leads to a dramatic loss of NMIIA signal, whereas Arp2/3 inhibition by CK-869 does not. SMIFH2 treatment by itself also does not lead to a loss of NMIIA signal, indicating that formins play a role in regulating *de novo* NMIIA filament assembly. Using triton insoluble fractionation assays, we confirmed that NMIIA is more cytosolic and does not associate with the cytoskeleton when formin is inhibited under Y-27632 washout, suggesting that RLC phosphorylation is blocked and NMIIA remains monomeric and assembly-incompetent. Our work suggests possible feedback between formin-nucleated actin assembly and myosin filament assembly to maintain homeostasis of actomyosin contractility.

P118/B121

Quantifying Non-muscle Myosin 2 Assembly Dynamics in 4D Super-resolution.

M. A. Quintanilla[1], H. Wu[1], M. Akamatsu[2], J. R. Beach[1]; [1]Loyola University Chicago, Chicago, IL, [2]University of California, Berkeley, Berkeley, CA.

How cells generate sufficient contractile forces to drive a diverse array of cellular processes is an outstanding question. Non-muscle myosin 2 is a motor protein that hydrolyzes ATP to contract actin filaments, generating the majority of contractile forces in non-muscle cells. To achieve the level of contractility needed for most processes, many myosin 2 filaments are needed. For decades, the only model to explain how a sufficient number of filaments are rapidly assembled was a model in which each filament was built individually. Recent work using high-resolution imaging demonstrated an alternative model in which nascent myosin 2 filaments are amplified by an actin-dependent partitioning process. We believe this partitioning process evolved as a dominant myosin 2 assembly mechanism to rapidly drive physiological levels of contraction - we observe the phenomenon in primary mouse fibroblasts, in 3D culture, on substrates of physiological stiffnesses, and in Drosophila haematopoietic cells. We do not understand the molecular mechanism for this phenomenon. Two mechanisms have been proposed (1) Single-filament partitioning - a single myosin 2 filament (~30 monomers) is ripped in two as dynamic actin fibers separate. (2) Multi-filament partitioning - Two or more myosin 2 filaments (>>30 monomers) are separated from one another as dynamic actin fibers separate. Differentiating these mechanisms is essential for understanding contractile force generation. To do this, we are using complementary methods of molecular counting and correlative light and electron microscopy (CLEM). Using protein nanocages with fixed numbers of subunits and fluorophores, we generated a standard curve of fluorescence with super-resolution imaging. By imaging endogenously-labeled EGFP-myosin 2 with identical conditions, we can interpolate the number of myosin 2 monomers present at the time of partitioning. Our in vitro, fixed-cell, and live-cell imaging suggest that 1) in vitro single filaments are 30 monomers, 2) live-cell bipolar structures can be upward of a single filament, and 3) partitioning events appear to occur at or above that of a single filament. Collectively, this work demonstrates that we can accurately quantify dynamic macromolecular complexes, and that we can use this technique to better understand the mechanism by which cells build contractile forces.

P119/B122

Investigating the Role of *Drosophila* Myosin7a and Its Binding Partner, M7BP, in Phagocytosis and Host Defense.

A. Hong, J. R. Sellers; National Heart, Lung, and Blood Institute, NIH, Bethesda, MD.

Drosophila myosin 7a (Dm7a) is an unconventional myosin required for the maintenance of the Johnston's organ (the auditory center in *Drosophila*) and the morphology of the bristle structures on the thorax. Both of these structures are formed by bundled arrays of actin. Here we show that Dm7a is involved in the process of engulfment of bacteria particles in the *Drosophila* larval hemocytes. These hemocytes have phagocytic capability and are important for the immune response during pathogen infection. Using the UAS/GAL4 system, we express GFP-Dm7a in the larval hemocytes and show that it induces the formation of filopodia in the hemocytes and Dm7a is localized in the cortical regions of the cell and in the filopodia. We imaged the uptake of fluorescently-tagged bacteria by hemocytes expressing GFP-Dm7a. When the bacteria contact the surface of the hemocyte, linear membrane ruffles appear and wrap around the bacteria. Occasionally an extended filopodia was seen to contact a bacterium and transport it back to the cell surface. We performed a phagocytosis assay to compare the ability of wildtype hemocytes versus hemocytes isolated from Dm7a mutant to engulf bacteria and found that Dm7a mutant is defective in the uptake of the bacteria, although bacteria can bind to the cell surface. We have also identified a binding partner of Dm7a using the C-terminus FERM domain as a bait in a yeast two hybrid system and named it *Myosin 7a Binding Protein* (M7BP). M7BP protein has a potential Rab-binding domain in the N-terminus. Immunoprecipitation experiments using M7BP antibody pulled down several *Drosophila* Rab proteins. RNAi knockdown of M7BP in the hemocytes affected the filopodia of the hemocytes and also compromised the ability of the hemocytes to engulf bacteria. When wildtype hemocytes are challenged with a high dose of bacteria, they utilize the process of macropinocytosis to increase the efficiency of clearing the invading pathogens. Membrane ruffles are initiated on the surface of the hemocytes that circularize to capture the bacteria and macropinocytic cups are formed which are subsequently internalized. In the RNAi knockdown lines of Dm7a and M7BP, abnormal formation of the macropinocytic cups were observed. We are exploring the functions of Dm7a, M7BP and Rab proteins in the larval hemocytes when challenged with bacteria.

P120/B123

SRNS-associated Myo1e Mutations Have Differential Effects on Myosin 1e Activity and Stability.

P. Liu[1], D. Perez[1], J. B. Karchin[2], C. D. Pellenz[1], S. E. Chase[1], M. Presti[1], E. L. Plante[1], C. E. Martin[3], S. Lovric[4], F. Hildebrandt[4], M. Krendel[1]; [1]SUNY Upstate Med University, Syracuse, NY, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]University of Guelph, Guelph, ON, CANADA, [4]Boston Children's Hospital, Boston, MA.

Mutations in the *MYO1E* gene, encoding Myosin 1e (Myo1e), are associated with steroid-resistant nephrotic syndrome (SRNS), a progressive kidney disease that can lead to kidney failure. Myo1e is a non-muscle motor protein moving along actin filaments that is enriched in the renal glomerular epithelial cells (podocytes). Using exome sequencing, novel *MYO1E* genotypes have been found in SRNS patients but whether these Myo1e variants directly result in SRNS is not known. Here, we set out to differentiate between the pathogenic and neutral novel *MYO1E* variants identified in SRNS patients (Sadowski et al., JASN, 2015, 26(6): 1279-89). Based on the allele frequency and conservation of the amino acid residues affected by the mutations, 7 non-truncated variants (containing point mutations and frameshift

mutations that do not cause early translation termination) were selected for further protein expression and localization analysis in cultured podocytes. EGFP-tagged human Myo1e constructs containing selected mutations were delivered into immortalized mouse podocytes using adenoviral vectors. We found that Myo1e-T119I was subject to heavy ubiquitination, suggesting that this mutant may be misfolded and unstable. Accordingly, T119I was diffusely localized in the cytosol and, unlike wild type Myo1e, it was not enriched at the cell-cell contacts or co-localized with clathrin-coated vesicles in podocytes. In contrast, Myo1e-D388H mutant was similar to the wild type myosin in protein expression level and cell-cell contact localization. Surprisingly, the rate of protein exchange of Myo1e-D388H at the cell-cell contacts, as measured by Fluorescence Recovery After Photobleaching, was decreased, and the localization of Myo1e-D388H to clathrin-coated vesicles was reduced, which suggests that this mutation alters Myo1e protein interactions in podocytes. Overall, our work has verified that two *MYO1E* alleles containing mutations in the motor domain, T119I and D388H, are likely to be pathogenic. By measuring Myo1e subcellular localization and dynamics in podocytes, we showed the distinct protein features of the two Myo1e mutants. The analysis workflow used in this project can be considered for future characterization of the pathogenicity of Myo1e variants that are identified in clinical studies.

P121/B124

It Takes Two: Ubiquitylation and P97-independent Extraction of a Cargo Adaptor from a Myosin V Complex Are Required in Parallel for the Termination of Organelle Transport.

S. Wong[1], N. Azad[1], L. Gal[2], N. Harpaz[2], M. Schuldiner[2], L. Weisman[1]; [1]University of Michigan, an n Arbor, MI, [2]Weizmann Institute of Science, Rehovot, ISRAEL.

Transport of organelles to their correct intracellular locations is essential for cellular function and homeostasis. The specificity of localization is achieved in part by molecular motors, which attach to cargoes, via cargo-specific adaptors, and actively transport them to their destinations. Our recent studies have revealed that the release of cargoes from the motor is as important as cargo attachment. Here, we show that both ubiquitylation and regulated extraction of the cargo adaptor is required to detach cargo from myosin V. In the budding yeast *S. cerevisiae*, the vacuole/lysosome is one of several cargoes moved by a myosin V motor. Early in the cell cycle, transport initiates when myosin V binds to the vacuole-specific adaptor, Vac17. Our previous work found that arrival of the vacuole at the bud cortex activates an E3 ubiquitin ligase. Vac17 is ubiquitylated and subsequently degraded by the proteasome. This was assumed to be the last step prior to degradation. Our unpublished studies reveal that a parallel pathway is essential to release the vacuole from myosin V. We found that Yck3, a Casein Kinase I isoform, and Vps41, a component of the HOPS complex, are required for the termination of vacuole transport. Moreover, while Yck3 and Vps41 are required for the degradation of Vac17, they are not required for Vac17 ubiquitylation. Instead, Yck3 and Vps41 regulate the phosphorylation of Vac17, an event required for the extraction of Vac17 from the myosin V complex. In a proteasome deficient mutant, Vac17 accumulates in puncta that are not strictly on the vacuole or with myosin V. This unique localization enabled us to discover that Yck3 and Vps41 act upstream of the proteasome to release Vac17 from the myosin V complex. Surprisingly, this extraction is not dependent on p97/Cdc48 or Vps4, AAA ATPases that extract proteins from membranes and/or protein complexes. Together, our data suggest that Yck3 and Vps41 dependent phosphorylation, concurrent with ubiquitylation, are part of a mechanism that detaches the vacuole from Myo2. These findings provide insight into how molecular motors deliver cargoes to the right place at the right time.

P122/B125

Modeling Mitochondrial Dynamics during Mitosis.

B. M. Fujita[1], S. Mogre[2], G. Lewis[3], O. A. Quintero[1]; [1]University of Richmond, RIchmond, VA, [2]University of California San Diego, San Diego, CA, [3]University of California San Francisco, San Francisco, CA.

MyosinXIX is an unconventional, mitochondria-associated motor that has been identified as a regulator of cell division. Cells depleted of MyosinXIX show two significant phenotypes: cytokinesis failure and, in cells that successfully divide, asymmetric mitochondrial partitioning from parent to daughter cells. Since the consequences of mitochondrial dynamics during mitosis are not well characterized, we developed two inductive models to address possible mechanisms behind the phenotypes previously observed. With the first model, based on energy calculations, we compared the energy required for membrane bending to the energy exerted by the actomyosin contractile ring to determine if the presence of mitochondria could interfere with cleavage furrow activity. These results suggest that mitochondria mislocalized to the cleavage plane could pose a physical impediment to cytokinesis. With the second model, based on simulations of particle movement in a cellular environment, we investigated if enhancing mitochondrial movement supported mitochondrial redistribution prior to anaphase onset by testing whether enhanced motility and/or particle size influenced particle positioning during the time frame of cellular division. Our results indicate that particle size was inversely related to final anisometry when only motility, but not fragmentation, was enhanced. Regardless of particle size, enhanced motility had the strongest effect on anisometry decrease over time and fragmentation alone had little to no effect on particle redistribution. Our results suggest that active transport is a major factor promoting symmetric particle distribution, and indicate that motor-assisted mitochondrial movement has a role in the proper partitioning of the organelle during mitosis.

P123/B126

The MyMOMA Domain of MYO19 Encodes for Distinct Miro-dependent and Miro-independent Mechanisms of Interaction with Mitochondrial Membranes.

J. L. Bocanegra[1], B. M. Fujita[1], N. R. Melton[1], J. M. Cowan[1], E. L. Schinski[1], T. Y. Tamir[2], M. B. Major[2], **O. A. Quintero**[1]; [1]University of Richmond, Richmond, VA, [2]University of North Carolina, Chapel Hill, NC.

MYO19 interacts with mitochondria through a C-terminal membrane association domain (MyMOMA). The specific mechanisms for localization of MYO19 to mitochondria are poorly understood. Using new promiscuous biotinylation data in combination with existing affinity-capture databases, we have identified a number of putative MYO19-interacting proteins. We chose to further explore the interaction between MYO19 and the mitochondrial GTPase Miro2 by expressing mchr-Miro2 in combination with GFP-tagged fragments of the MyMOMA domain and assaying for recruitment of MYO19-GFP to mitochondria. Coexpression of MYO19$^{898\text{-}970}$-GFP with mchr-Miro2 enhanced MYO19$^{898\text{-}970}$-GFP localization to mitochondria. Mislocalizing Miro2 to filopodial tips or the cytosolic face of the nuclear envelope did not recruit MYO19$^{898\text{-}970}$-GFP to either location. To address the kinetics of the Miro2/MYO19 interaction, we used FRAP analysis and permeabilization-activated reduction in fluorescence (PARF) analysis. MyMOMA constructs containing a putative membrane insertion motif but lacking the Miro2-interacting region displayed slow exchange kinetics. MYO19$^{898\text{-}970}$-GFP, which does not include the membrane-insertion motif, displayed rapid exchange kinetics, suggesting that the MYO19 interacting with Miro2 has higher mobility than MYO19 inserted into the mitochondrial outer membrane. Mutation of well-conserved, charged residues within MYO19 or within the switch I and II

regions of Miro2 abolished the enhancement of MYO19$^{898-970}$-GFP localization in cells ectopically expressing mchr-Miro2. Additionally, expressing mutant versions of Miro2 thought to represent particular nucleotide states indicated that the enhancement of MYO19$^{898-970}$-GFP localization is dependent on Miro2 nucleotide state. Taken together, these data suggest that membrane-inserted MYO19 is part of a larger complex, and that Miro2 plays a role in integration of actin- and microtubule-based mitochondrial activities.

Tubulins and Associated Proteins 1

From Cytoskeletal Function to Genome Stability: Resolving the Mystery of Tubulin Isotypes in Budding Yeast (Saccharomyces Cerevisiae).

E. Nsamba[1], A. Bera[1], M. Costanzo[2], C. Boone[2], M. Gupta[1]; [1]Genetics Development and Cell Biology, Iowa State University, Ames, IA, [2]Donnelly Centre for Biomolecular Research, University of Toronto, Toronto, ON, CANADA.

Microtubules (MTs) are dynamic cytoskeletal filaments polymerized from tubulin, a heterodimer of alpha- and beta- subunits. Cells typically contain multiple variants, or isotypes, of alpha- and beta-tubulin. Yet how tubulin isotypes underlie MT function remains largely obscure. Their clinical importance is also revealed by human neurological and fertility disorders caused by mutations in specific isotypes. We combined genetics, cell biology and quantitative fluorescence imaging to address the question of tubulin isotypes in the tractable budding yeast model. Unlike higher eukaryotes which have several, it has just one beta (tub2) and two alpha isotypes (Tub1 & Tub3). Yet, the contribution of each alpha isotype to cellular MT function is essentially unknown. Pioneering studies using deletion or overexpression of Tub1 or Tub3 proposed they may be functionally interchangeable and suggested differences result from expression levels. However, by employing improved methods we developed otherwise isogenic cells expressing solely Tub1 or Tub3 at levels comparable to total alpha-tubulin in wildtype cells. Our results demonstrate that each isotype normally contributes ~50% of total alpha-tubulin, showing the difference between them is not strictly quantitative. Moreover, lack of either isotype in cells expressing proper tubulin levels compromises microtubule function. Strikingly, cells harboring exclusively Tub1 or Tub3 display opposite sensitivities to microtubule poisons, altered regulation of microtubule dynamics, and differential contributions to mitotic spindle function. Additionally, we used genome-wide analysis to identify genetic interactions that are common or unique between either isotype, which further revealed the roles of each isotype in specific mitotic processes. Together, our genetic, functional, and quantitative imaging data reveal previously undetermined roles for tubulin isotypes, more explicitly in spindle positioning. The yeast spindle is positioned by two distinct pathways, and our results provide mechanistic insight into how Tub3 is vital for the proper function of the early/Kar9-dependent process while Tub1 is critical for efficient positioning by the late/Dyn1-dependent mechanism. MTs are indispensable for chromosome segregation in all eukaryotes. Thus, our results suggest tubulin isotypes are key components of the mechanisms that ensure mitotic fidelity. Overall, our study uncovers novel roles for tubulin isotypes and demonstrates how isotypes allow conserved MTs to function in diverse cellular processes.

Loss of Microtubule Acetylation Alters Touch Evoked Swimming and Fertility in Zebrafish.

S. Amirthagunanathan, W. Tseng, J. Gaertig, S. T. Dougan; University of Georgia, Athens, GA.

Microtubules carry out wide range of functions in cellular transportation, motility, cell division, structural components of cilia and flagella, cellular signaling etc. Microtubule (MT) post translational modification provides diversity that is necessary to carry out these diverse functions. MT acetylation, detyrosination, mono- and polyglycylation and mono-and polyglutamylation are some of the common MT posttranslational modifications. Past studies suggested that MT acetylation could play critical role in ciliary maintenance and normal neuronal functions. Objective of this study was to understand the role of MT acetylation in zebrafish. We generated a null mutant of MT acetylation enzyme, alpha-tubulin acetyltransferase (*atat1*). These *atat1-/-* mutants had no observable morphological phenotype in the embryo and as adults. An extensive analysis of behavioral responses in these mutants revealed a reduced touch-evoked swimming response in *atat1-/-* mutant embryos. These mutant embryos did not show any alterations in their muscle fiber organization or spontaneous swimming behavior, indicating alteration in sensory elements of touch response, consistent with the mouse mutants. Even though *atat1-/-* mutants did not show any alteration in male fertility, sperm motility analysis showed increase in non-progressive motility. We also found increased MT monoglycylation in *atat1-/-* adult testes and embryo pronephric duct. To understand whether this increase in MT monoglycylation could compensate for the loss of MT acetylation in *atat1-/-* mutant, we knocked out MT monoglycylation enzyme, Tubulin tyrosine ligase-like family, member 3 (*ttll3*) in *atat1-/-* mutant background. Preliminary data showed reduced female fecundity among zygotic double mutants of *atat1* and *ttll3*, indicating potential functional compensation of MT acetylation by MT monoglycylation. Our data suggest that MT acetylation could play important role in touch response, sperm motility and female fecundity. We also show that reduced MT acetylation may be compensated for by increased MT glycylation, suggesting that these PTMs may have partially redundant functions.

P126/B130

Differential Binding Affinity of Tau Repeat Region R2 with Neuronal-specific β-tubulin Isotypes.

V. V. Bhandare, B. V. Kumbhar, A. Kunwar; Indian Institute of Technology Bombay, Mumbai, INDIA.

Tau is a microtubule-associated intrinsically disordered protein abundantly expressed in brain and neuronal cells. The microtubule binding domain of tau located at C-terminal has four repeat regions R1, R2, R3 and R4; which binds and stabilizes the microtubule. In several neurodegenerative diseases, tau detaches from microtubules to form insoluble aggregates leading to tauopathy. Microtubules are made up of αβ tubulin heterodimeric subunits. Seven α-tubulin and nine β-tubulin isotypes have been reported in humans till date. These tubulin isotypes show variations in the residue composition mainly at C-terminal region and bind to motor proteins and anti-mitotic drugs differently. These tubulin isotypes show tissue specific expression as their relative proportion varies significantly in different type of cells. It is also known that tau binds differently to different cell lines and can either promote or demote microtubule polymerization. However, the relative binding affinity of tau to the different β-tubulin isotypes present in different cell lines is completely unknown. Therefore, we studied relative binding affinity of Tau repeat region R2 to neuronal specific tubulin isotypes βI, βIIb, and βIII using molecular modelling approach using recently reported CryoEM structure of tau repeat region R2. Our MD simulation results show a stable complex formation in between different tubulin isotypes and TauR2

which are mainly mediated by the interactions of H12 helix and C-terminal tail region of the αβ tubulin isotypes with TauR2. Our results suggest that tau shows differential binding affinity towards various β-tubulin isotypes. The order of binding affinity of TauR2 with β-tubulin isotypes is βIII> βIIb>βI. Thus, we find that TauR2 has greater affinity towards β tubulin isotypes which are abundantly expressed in neuronal cells i.e. βIII and βIIb. Our strategy can be potentially used to understand differential binding affinity of tau towards β tubulin isotypes present in other cell lines. We hope that knowledge of precise molecular origin of differential binding affinity of tau with β-tubulin isotypes present different cell types will pave the way for developing effective treatments against tau related disorders.

P127/B131

Alp7-Mto1 and Alp14 Synergize to Promote Interphase Microtubule Regrowth from the Nuclear Envelope.

W. Liu, C. Fu; University of Science and Technology of China, Hefei, CHINA.

Microtubules grow not only from the centrosome but also from various noncentrosomal microtubule organizing centers, including the nuclear envelope and pre-existing microtubules. The evolutionarily conserved proteins Mto1/CDK5RAP2 and Alp14/TOG/XMAP215 have been shown to be involved in promoting microtubule nucleation. However, it has remained elusive as to how the microtubule nucleation promoting factors are specified to various noncentrosomal microtubule organizing centers, particularly the nuclear envelope, and how these proteins coordinate to organize microtubule assembly. Here, we demonstrate that in the fission yeast *Schizosaccharomyces pombe*, efficient interphase microtubule growth from the nuclear envelope requires Alp7/TACC, Alp14/ TOG/XMAP215, and Mto1/CDK5RAP2. The absence of Alp7, Alp14, or Mto1 compromises microtubule regrowth on the nuclear envelope in cells undergoing microtubule repolymerization. We further demonstrate that Alp7 and Mto1 interdependently localize to the nuclear envelope in cells without microtubules and that Alp14 localizes to the nuclear envelope in an Alp7 and Mto1 dependent manner. Tethering Mto1 to the nuclear envelope in cells lacking Alp7 partially restores microtubule number and the efficiency of microtubule generation from the nuclear envelope. Hence, our study delineates that Alp7, Alp14 and Mto1 work in concert to regulate interphase microtubule regrowth on the nuclear envelope.

P128/B132

Tubulin Polyglutamylation Controls Axonal Traffic in Hippocampal Neurons.

S. Bodakuntla[1], A. Schnitzler[2], C. Villablanca[3], C. Gonzalez-Billault[3], I. Bieche[2], C. Janke[1], M. M. Magiera[1]; [1]Institut Curie, PSL Research University, CNRS UMR3348, F-91405, Orsay, FRANCE, [2]Institut Curie, PSL Research University, Department of Genetics, F-75005, Paris, FRANCE, [3]Center for Geroscience, Brain Health and Metabolism (GERO), Santiago, CHILE.

Axonal transport is one of the critical cellular processes maintaining the functions of neurons over a lifetime. Microtubules as ‘tracks’ for axonal transport are subject to posttranslational modifications (PTMs), which are expected to regulate neuronal transport. Polyglutamylation is one of the most prominent PTMs in neurons and therefore a potential mechanism involved in the regulation of axonal transport. To measure axonal transport at altered levels of polyglutamylation, we have established mouse models in which we invalidated one or several enzymes involved in tubulin polyglutamylation, and isolated primary hippocampal neurons from these mice. For particularly deleterious knockout models, we used conditional knockout alleles that can be switched to knockout in the cultured neurons

by infecting with cre-recombinase-expressing lentivirus. We have observed an increase in tubulin polyglutamylation in the neurons lacking main deglutamylases. We first measured mitochondria transport in hyperglutamylation conditions, and showed that the percentage of time mitochondria spent moving is reduced by about 50% as compared to wild type. This suggests that hyperglutamylation has an inhibitory effect on mitochondria transport. We furthermore showed an increased mitochondria mobility in neurons with decreased polyglutamylation, suggesting a fine-tuning effect of polyglutamylation levels on axonal transport. To investigate the specificity of this transport regulation, we studied the transport of other axonal cargoes. Transport of lysosomes, late endosomes and BDNF vesicles, similar to mitochondria, was negatively affected by hyperglutamylation. Thus, tubulin polyglutamylation could be a general tuning mechanism for axonal transport. Considering our earlier findings, which show that hyperglutamylation induces neurodegeneration, defects in axonal transport could be one of key molecular mechanisms that induce the degeneration of neurons with hyperglutamylation.

P129/B133

In Vitro Selection, Validation & Optimization of Synthetic Single-domain Antibodies for Tau.

P. Tafelmeyer[1], E. Dupré[2], C. Danis[2], A. Arrial[3], M. Colin[4], I. Landrieu[2], J. Rain[3]; [1]HYBRIGENICS Corp., Cambridge, MA, [2]UMR8576 CNRS-Lille University, Lille, FRANCE, [3]HYBRIGENICS Services, Evry, FRANCE, [4]Univ. Lille, Inserm, CHU-Lille, UMRS1172, Lille, FRANCE.

We have developed a new platform for VHH screening and have designed for this purpose a fully synthetic humanized naïve Llama VHH library containing 3x10exp9 antibodies, based on a unique scaffold with random complementary determining regions (CDRs) (1). We use a combination of phage display and subsequent yeast two-hybrid (Y2H) or yeast display screening to identify antibodies against native antigens and eventually intrabodies. From this library, we have successfully selected VHH against a variety of antigens including large proteins, haptens and receptors directly selected from cell surface expression. The affinity of our VHH is similar to the affinity of antibodies selected after animal immunization. Here, we will show the selection and characterization of VHH intrabodies against Tau and phospho-Tau. Several VHH sharing the same CDR3 recognition loop and binding to the same epitope in the C-terminus of Tau were selected. We further optimized the binding affinity of one of the Tau-specific VHH using a combination of limited random mutagenesis and Y2H screening. Our results validate the use of these VHH in *in vitro* assays, but also their application as intrabodies. (1) Moutel S. et al. Elife 2016, 19:5

Xmap215 Interacts with F-actin in the Embryonic Neuronal Growth Cone to Promote Microtubule-F-actin Interaction.

G. Cammarata[1], P. Slater[1], A. Samuelson[1], A. Magee[1], Y. Hu[2], A. Thawani[3], S. Petry[3], L. A. Lowery[1]; [1]Boston College, Chestnut Hill, MA, [2]Yale University, New Haven, CT, [3]Princeton University, Princeton, NJ.

Microtubules (MTs) that comprise part of the cytoskeleton in neuronal growth cones provide both a driving force and a protein signaling network that are required to extend growing ends of axons to their destinations. Pioneering MTs and their plus-end resident proteins, +TIPs, play integral roles during this growth in coordination with the F-actin cytoskeleton. However, it remains unclear how MTs and F-actin

dynamics are spatially coordinated to drive accurate growth cone steering. Here, we report that the well-characterized MT polymerase, XMAP215 (also known as CKAP5), plays an important role in mediating MT-F-actin interaction within the growth cone. We have recently conducted a series of experiments, using a combination of in *vivo and in vitro* techniques, *to* more clearly identify the mechanism of interaction of XMAP215 with F-actin. While partial knockdown of XMAP215 in *Xenopus* did not affect its well-known MT polymerization function, MT organization throughout the growth cone is affected in a drastic way. Specifically, we find that MT-F-actin alignment in the growth cone periphery is impaired, raising the question of whether XMAP215 might be mediating interactions between MTs and F-actin. We demonstrate that XMAP215 regulates MT-F-actin alignment through its N-terminal TOG 1-5 domains. Additionally, we show that XMAP215 directly binds to F-actin in *vitro* and co-localizes with F-actin in the growth cone periphery. Our findings provide the first strong evidence that XMAP215 coordinates MT and F-actin interaction in *vivo*. We suggest a model in which XMAP215 regulates MT extension along F-actin bundles into the growth cone periphery and that these interactions may be important to control cytoskeletal dynamics downstream of guidance cues.

All Tubulins Are Not Alike: Heterodimer Dissociation Differs among Different Biological Sources; Comparison with Dimer Association.

F. Montecinos-Franjola[1], S. K. Chaturvedi[2], P. Schuck[2], **D. L. Sackett**[1]; [1]National Institute of Child Health and Human Development, NIH, Bethesda, MD, [2]National Institute of Biomedical Imaging and Bioengineering, NIH, Bethesda, MD.

Tubulin, the subunit of microtubules, is a noncovalent heterodimer composed of one α and one β-tubulin monomer. Both tubulins are encoded by multiple genes (different isotypes), which are differentially expressed in different tissues and in development. Tubulin αβ dimers are found throughout the eukaryotes, and although very similar, are known to differ among organisms. We seek to investigate tubulins from different tissues and different organisms for a basic physical characteristic: heterodimer stability and monomer exchange between heterodimers. We have shown that mammalian brain tubulin heterodimers reversibly dissociate, following the mass action law. Dissociation yields native monomers that can exchange with added tubulin to form new heterodimers. Here, we compare the dissociation of tubulins from multiple sources, including from: mammalian (rat) brain, cultured human cells (HeLa cells), chicken brain, chicken erythrocytes, and the protozoan *Leishmania*. We used fluorescence-detected analytical ultracentrifugation to measure tubulin dissociation over a >1000-fold range in concentration and found that tubulin heterodimers from different biological sources differ in K_d by as much as 150-fold under the same conditions. Furthermore, when fluorescent tracer tubulins from various sources were titrated with unlabeled tubulin from a single source (rat brain tubulin), heterologous dimerization occurred, exhibiting similar affinities, in some cases binding even more strongly than with autologous tubulin. Heterodimers also associate into complexes larger than dimers, such as tetramers (dimers of dimers), and these low-level associations will be demonstrated. These results provide additional insight into the regulation of heterodimers of tubulin from different biological sources, suggesting that monomer exchange may contribute to the sorting of α- and β-tubulin monomers that associate following tubulin folding, and that dimer - dimer association may form species important for polymerization.

P132/B136

Reconstitution of the Human Gamma-tubulin Ring Complex with Recombinant Proteins.

M. Wieczorek, S. Ti, K. Molloy, B. Chait, T. Kapoor; Rockefeller University, New York, NY.

Microtubule formation in cells is regulated by the gamma-tubulin ring complex (gamma-TuRC), a large, multi-protein assembly found at microtubule organizing centers. The gamma-TuRC is thought to provide a polymerization template by mimicking an intermediate in the microtubule nucleation pathway. However, the composition of gamma-TuRCs isolated from native sources can vary across species, cell type, and even cell cycle stage. Further, the minimum set of proteins required for gamma-TuRC assembly and microtubule nucleating activity is not well-defined, which has limited detailed biochemical analyses of this complex. We have successfully reconstituted human gamma-TuRCs using 8 recombinant proteins overexpressed in insect cells. Recombinant gamma-TuRCs sedimented to ~30-34 S in sucrose gradients, and contained similar subcomponent stoichiometries as native human complexes, as determined by mass spectrometry. Negative stain electron microscopy revealed that reconstituted human gamma-TuRCs take on a “ring”-shaped organization with a diameter of ~30 nm, consistent with previous descriptions of native gamma-TuRCs. We developed single molecule TIRF microscopy assays to demonstrate and analyze microtubule nucleation from individual gamma-TuRCs, confirming the integrity of our recombinant material. Our work provides insight into the biochemistry of this essential complex and opens the door to mechanistic studies of gamma-TuRC function using bottom-up approaches.

P133/B137

Functional Characterization of the Echinoderm Microtubule-Associated Protein-Like (EML) Family.

S. Schenk, A. Lopez, S. Bechstedt; McGill, Montreal, QC, CANADA.

Among the most abundant microtubule associated proteins (MAPs) found in the mitotic spindle are members of the echinoderm-microtubule-associated protein-like (EML) family. This understudied MAP family is highly conserved from echinoderms (e.g. sand dollars) to humans and is known to be involved in cell division. Misregulation of EMLs has been linked to various cancers and has recently been shown to play a role in the formation of the cerebral cortex. Despite their apparent role in cell division and their connection to human diseases, it remains unknown how EMLs bind to or regulate microtubule function in cells. Using turbidity as well as TIRF microscopy assays, we characterize the effects of EML proteins on microtubule stability and dynamics. We also present data from EML2 knock-out cells, which show abnormal growth and morphology. Our research provides new insights into the function of various members of the EML protein family.

P134/B138

Conformational Diversity of Dynactin Sidearm.

K. SAITO[1], T. Kobayashi[2], T. Murayama[2], Y. Y. Toyoshima[1]; [1]The University of Tokyo, Tokyo, JAPAN, [2]Juntendo University School of Medicine, Tokyo, JAPAN.

Dynactin is a huge protein complex, which interacts with various microtubule binding proteins and vesicle binding proteins. It regulates the motility of dynein and recent cryo-EM studies revealed its averaged structure. However, our knowledge on the structure of sidearm in dynactin complex is still limited probably because of its flexibility. What conformation the sidearm adopts is an especially important question because it takes part in interaction with dynein, microtubules, and plus-end binding

proteins. Here, we report various conformations of dynactin sidearm observed by electron microscopy. We found that a basal part of sidearm (shoulder domain) was either bound to or released from the Arp1 rod and the ratio of these forms was dependent on the ionic strength. Furthermore, the dynein-binding domain in the sidearm (coiled-coil 1) adopted either a folded or an extended form. Our results indicate that dynactin complex has several intramolecular interaction sites, which enables dynactin to adopt various conformations. These features must be a result of a remarkably complicated submolecular architecture of dynactin complex and be important for dynactin to work as a versatile regulator of dynein motility in the cell.

P135/B139

The Roles of Two γ-tubulin-associated Proteins in Embryos and Differentiated Cells in *Caenorhabditis Elegans*.

N. Haruta, M. Nakajo, C. Uchiyama, A. Sugimoto; Graduate School of Life Sciences,Tohoku University, Sendai, JAPAN.

The γ-tubulin complex (γTuC) is a major nucleation factor of microtubules (MTs), accumulating to microtubule-organizing centers (MTOCs), such as centrosomes in animal cells. There are two types of γTuCs; the γ-tubulin small complex (γTuSC) composed of the γ-tubulin and GCP2 and GCP3, and the γ-tubulin ring complex (γTuRC) assembled by several γTuSCs and other proteins including GCP4-6 and MOZART1. In *Caenorhabditis elegans,* GCP-4-6 are not conserved, thus, the composition and regulatory mechanisms of the γTuC are implicated to be different from other organisms. As γ-tubulin-associated proteins, we biochemically identified two *C. elegans* proteins, GTAP-1 and -2. Yeast two-hybrid assays indicated that GTAP-1 and-2 interact with γ-tubulin and GIP-2/GCP2. Live-imaging microscopy showed that GTAP-1 and -2 localized at the PCM throughout the cell cycle in a γ-tubulin-dependent manner. The RNAi knockdown and mutations of GTAP-1 and -2 resulted in reduction of γ-tubulin proteins at centrosomes, but embryonic development was largely unaffected. However, the *gtap-1* mutant showed abnormal morphology of the germline cells and the brood size was significantly reduced. In these animals, the organization of MTs and cell membrane of the syncytial germline was disrupted, which might be caused by the failure of γTuC localization at the germ cell membrane. On the other hand, the *gtap-2* mutant showed no abnormality in the germline. These data suggest that GTAP-1 may be involved in the γTuC targeting to the germline cell membrane.

P136/B140

The Role of Alpha-tubulin Acetylation in *Drosophila*Oogenesis.

M. An tel, T. Simao, V. Baena, R. Norris, N. Shuhaibar, M. Terasaki, M. Inaba; University of Connecticut Health Center, Farmington, CT.

During *Drosophila* oogenesis, microtubules are known to play several key roles including oocyte specification and differentiation, the transport of materials into the oocyte from neighboring cells, and specifying the axis of the oocyte for embryonic development. The diverse functions of microtubules are regulated by the post-translational modifications (PTMs) of the microtubule subunits, alpha- and beta-tubulin, which are subjected to a wide array of PTMs. One such PTM is acetylation of the conserved K40 residue of alpha-tubulin. Alpha-tubulin K40 acetylation has been reported to be enriched on stable microtubules where it is suggested to confer increased flexibility to microtubules and promote resistance to breakage from mechanical forces. K40 acetylation is facilitated by an alpha-tubulin

acetyltransferase, MEC17, which is counterbalanced by the activity of the major tubulin deacetylase, HDAC6. To study alpha-tubulin acetylation in oogenesis, we focused on a *Drosophila* gonad-specific Mec17 (Mec17g) and generated a knockout fly with the Mec17g locus removed (Mec17g KO). Mec17g KO flies exhibited age-dependent defects in fertility and egg formation. The defect in egg formation could be rescued by the somatic follicle cell-specific expression of either Mec17g or alpha-tubulin K40Q (an acetylated alpha-tubulin mimic), demonstrating the requirement of alpha-tubulin K40 acetylation in follicle cells for proper egg development. An alysis of Mec17g KO follicle cells by electron microscopy revealed the absence of stacked endoplasmic reticulum (ER) sheets—ER structures which have been hypothesized to permit maximal protein synthesis in professional secretory cells—suggesting a role for Mec17 in the formation and/or maintenance of stacked ER sheets.

P137/B141

Microtubule Acetylation Is Required for Mechanosensation in *Drosophila*.

S. Rogers; University of North Carolina-Chapel Hill, Chapel Hill, NC.

At the cellular level, α-tubulin acetylation alters the structure of microtubules to render them mechanically resistant to compressive forces. How this biochemical property of microtubule acetylation relates to mechanosensation remains unknown, although prior studies have shown that microtubule acetylation influences touch perception. Here, we identify the major *Drosophila* α-tubulin acetylase (dTAT) and show that it plays key roles in several forms of mechanosensation. dTAT is highly expressed in the larval peripheral nervous system (PNS), but it is largely dispensable for neuronal morphogenesis. Mutation of the acetylase gene or the K40 acetylation site in α-tubulin impairs mechanical sensitivity in sensory neurons and behavioral responses to gentle touch, harsh touch, gravity, and vibration stimuli, but not noxious thermal stimulus. Finally, we show that dTAT is required for mechanically induced activation of NOMPC, a microtubule-associated transient receptor potential channel, and functions to maintain integrity of the microtubule cytoskeleton in response to mechanical stimulation.

P138/B142

Understanding the Role of Yeast Map She1 in Dynein-Mediated Spindle Positioning.

K. H. Ecklund[1], M. E. Bailey[2], K. A. Kossen[1], C. J. Dietvorst[1], C. L. Asbury[2], S. M. Makrus[1]; [1]Colorado State University, Fort Collins, CO, [2]University of Washington School of Medicine, Seattle, WA.

During cell division in budding yeast, cortically anchored dynein motors position the mitotic spindle within the bud neck, a narrow constriction between the mother and daughter cells. Dynein is assisted by numerous factors to perform this function, including the microtubule-associated protein (MAP) She1, which is a potent inhibitor of dynein motility in *vitro*. We previously found that She1 supports dynein-mediated spindle orientation by promoting the ability of dynein to move the spindle across the bud neck, raising the possibility that She1 affects this process by supporting nuclear transit into the narrow constriction of the neck. Here we set out to assess the role of She1 in dynein-mediated nuclear and spindle positioning, and the various factors that govern this process. We find that although She1 can promote a persistent force generating state of dynein, loss of She1 had no discernible effect on the success rate for dynein-mediated nuclear migration into the narrow bud neck. Close inspection of dynein-mediated spindle movements revealed that loss of She1 does not compromise spindle neck crossing directly, but increases the duration of time the spindle spends in close proximity of the mother and daughter cell cortices. Our data indicate this is likely a consequence of the increased dynein activity

also seen in cells lacking She1, suggesting that by attenuating dynein activity, She1 maintains the spindle within close proximity of the bud neck, the site of anaphase onset, and the future site of cell division. Although She1 has previously been shown to affect dynein-dynactin interaction in cells, we find that the ability of She1 to restrict dynein-mediated spindle movements to the bud neck region likely occurs in a dynactin-independent manner. Moreover, observations of cells expressing a mutant tubulin or a mutant dynein, which both exhibit reduced She1 binding, revealed an increased cortical proximity phenotype similar to that observed in *she1Δ* cells. Taken together, our data support a model whereby She1 attenuates dynein activity through direct interactions with the dynein MTBD and the microtubule, which ensures appropriate positioning of the mitotic spindle at the future site of cytokinesis.

P139/B143

Development of an Optogenetic Tool to Reversibly Control Microtubule Acetylation.

A. Deb Roy, E. Gross, G. Pillai, A. Kim, T. Inoue; Johns Hopkins University, Baltimore, MD.

Acetylation of α-tubulin at lysine-40 is a highly conserved post-translational modification, which is reported to stabilize microtubule against bending stresses. Microtubule acetylation is exclusively catalysed by α-acetyltransferase-1 (ATAT1), whose only known substrate is α-tubulin. Despite being implicated in a wide array of physiological phenomena including ciliary function, cell motility and mechanosensation, the precise role of microtubule acetylation in these events is not well understood, due to a limited understanding of ATAT1 regulation and lack of tools to specifically control microtubule acetylation. Here we report development of an optogenetic tool to control microtubule acetylation in live cells in a reversible manner. We observed that ATAT1 shuttles between nucleus and cytoplasm but maintains a predominantly cytoplasmic localization by active nuclear export in a Crm1-dependent manner. Unlike wild-type ATAT1, exogenous expression of nuclear localized ATAT1 catalytic domain did not significantly increase microtubule acetylation, suggesting that nuclear export may play a role in regulating ATAT1 access to microtubules and thus regulate acetylation levels. We identified a conserved Leptomycin-B sensitive nuclear export sequence in the disordered carboxy-terminal region, which is critical for nuclear export but not catalytic activity of ATAT1. Based on these findings, we hypothesized that inducible translocation of ATAT1 catalytic domain from nucleus to cytoplasm should allow us to control microtubule acetylation levels. We modified the previously described Light-inducible nuclear export system (LEXY) to reduce its dark-state activity and tethered the catalytic domain of ATAT1 to its carboxy-terminus. LEXY-ATAT1 was predominantly nuclear in dark and was rapidly shuttled to the cytoplasm upon blue light stimulation in a reversible manner. A lit mutant of LEXY(lit)-ATAT1 induced around two-fold increase in microtubule acetylation levels in HeLa cells, as compared to a non-transfected cells or cells expressing a dark mutant of LEXY(dark)-ATAT1. HeLa cells expressing LEXY-ATAT1 exposed to light for 4 hours showed a similar two-fold increase in microtubule acetylation compared to those kept in dark, validating the functionality of the tool. Thus, we have developed a powerful tool to control microtubule acetylation that will provide various applications exploring cell motility and ciliary functions.

Systems Biology Identifies Gleevec as a Specific Inhibitor of CLIP-170S, a Novel +Tip Isoform, Which Causes Taxane Resistance in Cancer Cells and Patients by Obstructing the Microtubule Pore.

P. V. Thakkar[1], K. Kita[1], G. Galletti[1], N. S. Madhukar[1], E. V. Navarro[1], K. Cleveland[1], I. Barasoain[2], H. V. Goodson[3], D. L. Sackett[4], J. F. Diaz[2], O. Elemento[1], M. A. Shah[1], P. Giannakakou[1]; [1]Weill Med College/Cornell University, New York, NY, [2]Centro de Investigaciones Biológicas, Madrid, SPAIN, [3]University of Notre Dame, Notre Dame, IN, [4]Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD), NIH, Bethesda, MD.

Taxanes are widely used in the treatment of solid tumor patients including gastric cancer (GC). Post-hoc analysis of the clinical trial that led to docetaxel approval in GC, revealed that patients with diffuse histological subtype were intrinsically resistant to taxanes. As yet, the molecular basis of clinical drug resistance remains poorly elucidated. Using a panel of GC cell lines, we identified a subset with intrinsic taxane resistance due to impaired drug-target engagement, in the absence of tubulin mutations or decreased drug accumulation. We discovered a novel, short variant of the microtubule (MT) +TIP binding protein CLIP-170, hereafter CLIP-170S, which was preferentially expressed in resistant cells. Mass-spec proteomics and 5'RACE showed that CLIP-170S lacked the first 150 amino acids, thus, missing the Cap-Gly domain required for +TIP localization. Microscopy of endogenous or exogenous proteins revealed that CLIP-170S was mislocalized from +TIP to the MT lattice in contrast to the canonical CLIP-170. Stable CLIP-170S knock down (KD) entirely reversed taxane-resistance (~300 fold), directly establishing CLIP-170S as the cause of taxane resistance. Quantitation of Flutax-2 (fluorescently labeled taxane) binding kinetics by live-cell imaging of native cytoskeletons in sensitive and resistant cells, showed that Flutax-2 dissociated faster from MTs in CLIP-170S-expressing resistant cells due to slower association rate. CLIP-170S-KD fully restored Flutax-2 binding to MTs, indicating that CLIP-170S impedes taxane-MT interaction. As taxane binding to MT lumen requires entry via the MT pore, we used chemical probes binding at the outer-only (hexaflutax) or luminal (cyclostreptin) pore sites and showed reduced binding of both compounds to resistant cell cytoskeletons. In contrast, CLIP-170S had no effect on peluroside whose MT binding does not require access through the pore. Together, these data indicate that CLIP-170S obstructs the MT pore, preventing drug access to the MT lumen and causing taxane resistance. Clinically, we found CLIP-170S to be expressed in ~60% of GC patient tumors and that its expression was significantly associated with resistance to cabazitaxel monotherapy. Computational analyses of RNAseq data from sensitive and resistant cells predicted Gleevec (Imatinib) as a drug that could overcome taxane resistance. Indeed, we showed that Gleevec reversed taxane resistance by specific depletion of CLIP-170S protein. Taken together, these data reveal an entirely novel mechanism of taxane resistance via obstruction of the MT pore by the previously unrecognized CLIP-170S. We further found CLIP-170S to be highly prevalent in patient tumors and identified Gleevec as the first specific inhibitor of CLIP-170S.

Systematic Characterization of a Large Number of Microtubule-Associated Proteins Using Purification-free Tirf-reconstitution Assays.

A. S. Jijumon[1,2,3], S. Bodkuntla[1,3], M. Genovo[1,2], M. Bangera[4], F. Maksut[1,2], M. M. Magiera[1,2], C. Janke[1,2,3]; [1]Institut Curie, Paris, FRANCE, [2]University of Paris Saclay, Orsay, FRANCE, [3]PSL University, Paris, FRANCE, [4]Instem, Bangalore, INDIA.

The microtubule cytoskeleton is complex filamentous network involved in diverse functions such as cell division, cell shape, neuronal differentiation, ciliary beating. Strict regulation of microtubule functions is therefore of high importance for the integrity of the healthy cell, and perturbations are often linked to diseases like cancer, ciliopathies and neurodegeneration.In a cellular context, microtubule properties can be controlled by two major mechanisms: by the expression of alternative tubulin genes and post-translational modifications of tubulin, or/and via the interaction of microtubules with a large variety of microtubule-associated proteins (MAPs). Our knowledge of such interactors has been continuously enriched over the past decades, but up to this date no systematic studies exist that aim to describe and categorize these proteins according to their binding mechanisms and structural effects on microtubules. In the present work, we have developed an assay for rapid and systematic analysis of around 40 MAPs, using cleared lysates of cultured human cells in which we overexpress the MAPs of interest. The dynamic behaviour of growing microtubule in presence of different MAPs were monitored over time using total internal reflection fluorescence (TIRF) microscopy. This allows us to study the behaviour of large number of MAPs in a situation close to their natural environment, but eliminating cellular complexity coming from different organelles and crammed cytoskeleton filaments inside the confined intracellular space. Indeed, most MAPs were nicely soluble in our extract approach, while purification often led to protein precipitation. Our novel approach allowed us to define several novel proteins as bona-fide MAPs. We show that previously uncharacterized MAPs have strikingly different effects on microtubule polymerization and microtubule structure, thus creating a variety of distinct microtubule arrays. Also, our cell free TIRF assays provide the evidence for a direct role of many MAPs in the coordination of microtubule and actin cytoskeleton arrays. Moreover, MAPs such as Tau and MACF1 clearly show a preference for PTM-rich microtubules. Our experiments will allow for a better mechanistic understanding of how MAPs and tubulin heterogeneity together control cytoskeleton functions.

Microtubule Glycylation Promotes Attachment of Basal Bodies to the Cell Cortex.

A. Junker[1], A. Soh[1], E. O'Toole[2], J. Meehl[2], M. Guha[3], M. Winey[4], J. Honts[5], J. Gaertig[3], C. Pearson[1]; [1]University of Colorado, an schutz Medical Campus, Aurora, CO, [2]University of Colorado, Boulder, CO, [3]University of Georgia, Atlanta, GA, [4]University of California, Davis, CA, [5]Drake University, Des Moines, ID.

Motile cilia generate directed hydrodynamic flow that is important for the motility of cells and extracellular fluids. To maximize the use of forces generated by beating motile cilia, cells organize and orient hundreds of motile cilia into polarized arrays. Basal bodies (BBs) nucleate and position motile cilia at the cell cortex. Cytoplasmic BB-associated microtubules are conserved structures that extend from BBs and reinforce BB and cilia positioning. Using the ciliate, *Tetrahymena thermophila*, we show that BB-appendage microtubules attach to the cell cortex through several independent orientations. BB-

appendage microtubules are assembled shortly after new BB assembly and finish their elongation prior to when BBs nucleate cilia. These BB-appendage microtubules are specifically marked with post translational modifications of tubulin, including glycylation. Mutations that prevent glycylation shorten BB-appendage microtubules and disrupt BB organization, orientation and cortical attachment. Microtubule glycylation is specifically important for maintaining the position of BBs against the forces from high-frequency ciliary beating. Consistent with the attachment of BB-appendage microtubules to the cell cortex for BB positioning, mutations that disrupt the cellular cortical cytoskeleton similarly disrupt the cortical attachment and positioning of BBs. In summary, BB-appendage microtubules promote the organization of ciliary arrays through attachment to the cell cortex.

Microtubule Dynamics and its Regulation 1

Domain an alysis of PRC1/Ase1 Reveals Distinct Interactions with Microtubule Surface That Regulate an aphase Spindle Elongation.

E. Thomas, A. Ismael, J. K. Moore; University of Colorado - an schutz Medical Campus, Aurora, CO.

Proper chromosome segregation during mitosis requires structural rearrangement of the microtubule network. Microtubule crosslinkers such as kinesin-5 and PRC1/Ase1 are key to this process, promoting the formation and elongation of a bipolar spindle. During mitosis Ase1 localizes to antiparallel overlapping microtubules, but how Ase1 activity is regulated to promote the progression of structural re-arrangements in the spindle is poorly understood. We investigated the domains of Ase1 that are required for spindle function and discovered important roles for the microtubule-binding spectrin-homology domain and the disordered carboxy-terminal domain. We hypothesize that Ase1 loading and diffusion along the microtubule surface is mediated by phospho-regulated interactions between these Ase1 domains and the negatively-charged carboxy-terminal tails of the tubulin subunits. In support of our hypothesis, we find that a partial truncation of the Ase1 carboxy-terminal domain reduces anaphase Ase1 loading on to the spindle and disrupts Ase1's ability to dynamically slow anaphase B elongation rates. Complementing these experiments, deletion of the tubulin carboxy-terminal tails results in increased pre-anaphase Ase1 spindle localization. However, this increased localization is dependent on Ase1's carboxy-terminal domain, as truncations of both the Ase1 carboxy-terminal domain and the tubulin carboxy-terminal tails result in decreased spindle localization. Furthermore, the spectrin-homology domain contains three positively-charged basic amino acids predicted to interact with the β-tubulin tail, and mutating these three amino acids to alanine impacts Ase1 function in a distinct manner from carboxy-terminal domain truncations. These mutations decrease Ase1's spindle localization and consistently reduce Ase1's braking ability throughout anaphase B spindle elongation. Faster spindle elongation impairs spindle stability and may impact genome integrity. Overall, our results suggest Ase1 uses multiple binding interfaces with the microtubule to regulate distinct stages of spindle formation and function, and that this mechanism involves regulated interactions with the tubulin carboxy-terminal tails to provide a dynamic braking system during anaphase.

P144/B148

Katanin Grips the Beta-tubulin Tail through an Electropositive Double Spiral to Sever Microtubules.

E. A. Zehr, A. Szyk, E. Szczesna, A. Roll-Mecak; National Institutes of Health, Bethesda, MD.

The AAA ATPase katanin severs microtubules. It is critical in cell division, centriole biogenesis and neuronal morphogenesis and its mutation causes microcephaly. The microtubule templates katanin hexamerization and activates its ATPase. The structural basis for these activities and how they lead to severing is unknown. Here, we show that beta-tubulin tails are necessary and sufficient for severing. Cryo-EM structures reveal the essential tubulin tail glutamates gripped by a double spiral of electropositive loops lining the katanin central pore. Each spiral couples allosterically to the ATPase and binds alternating, successive substrate residues, with consecutive residues coordinated by adjacent protomers. This tightly couples tail binding, hexamerization and ATPase activation. Hexamer structures in different states suggest an ATPase-driven, ratchet-like translocation of the tubulin tail through the pore. An essential disordered region outside the AAA core anchors katanin to the microtubule while the AAA motor exerts the forces that extract tubulin dimers and sever the microtubule.

Unc-45a Is a Microtubule Severing Protein.

A. Mooneyham, J. Habicht, M. Shetty, M. Gardner, **M. Bazzaro**; University of Minnesota, Minneapolis, MN.

UNC-45A, is a highly conserved member of the UCS (UNC45A/CRO1/SHE4P) protein family [1-3]. We have shown that it plays an important role in regulating cytoskeletal-associated functions including cytokinesis[4], exocytosis[5], cell motility[4], and neuronal development[6]. Most of what we currently know about UNC-45A pertains to its role as a regulator of the actomyosin system. Emerging studies from both our and other laboratories support a role of UNC-45A outside of actomyosin regulation. This includes studies showing that UNC-45A: regulates gene transcription, co-fractionates with gamma tubulin and regulates centrosomal positioning and is found in the same subcellular fractions where MT-associated proteins are. Recent studies from our laboratories indicate that UNC-45A functions as a Microtubule Associated Protein (MAP) with MT destabilizing properties[7, 8]. Specifically: ***a)*** using TIRF microscopy, we found that UNC-45A directly binds to MTs in the absence of any additional cellular cofactors and acts as an ATP-independent MT destabilizer, ***b)*** UNC-45A destabilizes MTs in *vivo in* absence of its myosin binding domain and in even in presence of the myosin II inhibitor blebbistatin, and ***c)*** UNC-45A is overexpressed in paclitaxel resistant cancer cells. Mechanistically, UNC-45A's MT destabilizing activity is consistent with MT bending and severing. Inhibition of UNC-45A causes mitotic defects consistent with excessive MT stability and restores cancer cells' sensitivity to paclitaxel. These findings reveal novel and significant roles for UNC-45A in regulation of cytoskeletal dynamics, broadening our understanding of the basic mechanisms regulating MT stability and human cancer susceptibility to paclitaxel. ***References*** 1. XMAP215 Promotes Microtubule Catastrophe by Promoting Ragged Microtubule End Structures.

V. Farmer, G. Arpag, S. Hall, M. Zanic; Vanderbilt University, Nashville, TN.

The microtubule cytoskeleton is essential for a variety of cellular processes, including intracellular transport, cell motility, and cell division. Dynamic remodeling of the microtubule network is facilitated by microtubule dynamic instability, the stochastic switching of individual microtubules between phases of growth and shrinkage. A growing microtubule maintains a stabilizing cap of GTP-tubulin at its end; if this GTP-cap is lost, the microtubule undergoes 'catastrophe' and switches into a phase of shrinkage. The stabilizing GTP-cap can be visualized through microtubule end-localization of EB proteins, known to recognize the nucleotide state of tubulin within the microtubule. An increase in microtubule growth rate, when achieved by increasing tubulin concentration in *vitro*, correlates with an increase in the size of the 'EB comets', indicating that the GTP-cap size scales with the microtubule growth rate. At the same time, increasing tubulin concentration results in a lower catastrophe frequency, consistent with the hypothesis that catastrophe frequency negatively scales with the GTP-cap size. However, microtubule growth rates achieved with tubulin alone in *vitro* are an order of magnitude lower than those typically observed in cells. Fast microtubule growth rates can be reconstituted in *vitro* through synergistic effects of EB1 and XMAP215, a well-studied microtubule polymerase. How this combination of proteins impacts microtubule catastrophe frequency and the GTP-cap size is unknown. Here, we observe that fast microtubule growth rate achieved using XMAP215 and EB1 in *vitro* correlates with increased GTP-cap size. Interestingly, we show that the addition of XMAP215 simultaneously increases both microtubule growth rate and catastrophe frequency, contrary to what is observed when microtubule growth rates are increased using tubulin alone. Using total internal reflection fluorescence with structured illumination microscopy and negative stain electron microscopy, we find that microtubules grown with XMAP215 display a higher frequency of ragged microtubule end structures, in which a subset of protofilaments are growing faster than others. The structural destabilization of growing microtubule ends correlates with the observed increase in microtubule catastrophe. Our results underscore the role of the dynamic evolution of microtubule end structure in dictating overall microtubule stability.

P147/B151

The Concerted Actions of Tip1/clip-170, Klp5/kinesin-8, and Alp14/xmap215 Regulate Microtubule Catastrophe at the Cell End.

X. Niu, 230026, F. Zheng, C. Fu; University of Science and Technology of China, Hefei, CHINA.

Spatial regulation of microtubule catastrophe is important for controlling microtubule length and consequently contributes to the proper establishment of cell polarity and cell growth. The +TIP proteins including Tip1/ CLIP-170, Klp5/Kinesin-8, and Alp14/XMAP215 reside at microtubule plus ends to regulate microtubule dynamics. In the fission yeast Schizosaccharomyces pombe, Tip1 and Alp14 serve as microtubule stabilizing factors while Klp5 functions oppositely as a catastrophe promoting factor. Despite that Tip1 has been shown to play a key role in restricting microtubule catastrophe to the cell end, how Tip1 fulfills the role remains to be determined. Employing live-cell microscopy, we showed that the absence of Tip1 impairs the localization of both Klp5 and Alp14 at microtubule plus ends but the absence of Klp5 prolongs the residence time of Tip1 at microtubule plus ends. We further revealed that Klp5 accumulates behind Tip1 at microtubule plus ends in a Tip1 dependent manner. In addition, artificially tethering Klp5 to microtubule plus ends promotes premature microtubule catastrophe while

tethering Alp14 to microtubule plus ends in the cells lacking Tip1 rescues the phenotype of short microtubules. These findings establish that Tip1 restricts microtubule catastrophe to the cell end likely by spatially restricting the microtubule catastrophe activity of Klp5 and stabilizing Alp14 at microtubule plus ends. Thus, the work demonstrates the orchestration of Tip1, Alp14, and Klp5 in ensuring microtubule catastrophe at the cell end.

P148/B152

Spastin Is a Dual-function Enzyme That Severs Microtubules and Promotes Their Regrowth to Increase the Number and Mass of Microtubules.

Y. Kuo[1], O. Trottier[1], M. Mahamdeh[2], J. Howard[1]; [1]Yale University, New Haven, CT, [2]Harvard Medical School, Boston, MA.

Microtubules are dynamic cytoskeletal filaments that play central roles in eukaryotic cell division, migration and tissue development. One important family of microtubule regulators comprises the severases—spastin, katanin and fidgetin that use ATP-hydrolysis to cut microtubules into short fragments. Whereas one might anticipate severing as a destructive process for microtubules network, previous in *vivo* studies have demonstrated that inhibiting these enzymes contradictorily decreases microtubule number and mass in cells, suggesting microtubule severases may possess nucleation-like activity. To resolve this paradox, we reconstituted a dynamic microtubule severing system in *vitro and* found that *Drosophila* spastin is a dual function microtubule regulator. Besides the canonical severing activity, spastin slows down microtubule shrinkage and increases rescue through an ATP-independent mechanism. Accumulation of spastin on the shrinking microtubule ends is observed in optical microscopy and may underlie its effect on microtubule shrinkage and rescue. By increasing rescue and slowing down shrinkage, spastin switches the microtubules into their unbounded growth regime and promotes the regrowth of severed microtubule fragments. This leads to the increase in microtubule number and mass, accounting for the in *vivo* phenotype of spastin. An extended dynamic instability model demonstrates that spastin's effect on microtubule dynamics is essential for increasing microtubule mass and number. The mathematical model further reveals that severing activity and microtubule growth rate are the key factors for determining the steady-state length distribution, and the functional relation between severing rate and steady-state mean length closely resembles a power law. These results provide a quantitative basis of how severases can modulate microtubule network in the complex cellular environment.

Brownian Dynamics Modeling of Microtubule Dynamics and Force Generation Offers a Role for the Flared Morphology of Growing Microtubule Tips.

N. Gudimchuk[1,2], E. Ulyanov[1], D. Vinogradov[2], E. O'Toole[3], F. Ataullakhanov[1,2], J. McIntosh[3]; [1]Physics Department, Lomonosov Moscow State University, Moscow, RUSSIAN FEDERATION, [2]Center for theoretical problems of physico-chemical pharmacology, Russian academy of sciences, Moscow, RUSSIAN FEDERATION, [3]Department of M.C.D. Biology, University of Colorado, Boulder, CO.

Microtubules (MTs) are essential cytoskeletal polymers in all eukaryotic cells. Thanks to their dynamic instability, MTs efficiently search and capture chromosomes in mitosis. Upon association with chromosome-bound kinetochore proteins, MT tips produce pulling and pushing forces that aid in the accurate segregation of sister chromatids. Understanding of the mechanisms that underlie these

processes has been limited by our lack of knowledge of MT tip structure and the conformational changes responsible for MT switches between assembly and disassembly. In contrast to most previous models, our recent descriptions of MT tips by electron tomography in vivo (six species) and in vitro (under several experimental conditions) found that the ends of these dynamic polymers display flaring protofilaments in both growing and shrinking states (McIntosh et al., 2018). Curved protofilament morphology at MTs ends may have profound implications for MT dynamics, for mechanical force generation, and for the regulation of both processes by associated proteins. However, existing models for MT dynamics have not yet explicitly considered this structural feature, nor have they employed data from MT force generation experiments. Here we use a Brownian dynamics method to construct and systematically analyze a comprehensive model for MT dynamics and force production. We demonstrate that a description of MT assembly and disassembly with flared ends can be achieved under a range of conditions, using simple tubulin lateral interaction energy potentials. However, force generation experiments put constraints on model parameters, pointing to the presence of a high and steep activation energy barrier in the lateral tubulin interaction energy potential. When properly constrained, the model describes the development of large pulling forces by shortening MTs and considerable pushing forces by growing MTs. Moreover, the flared morphology of growing MT tips enables sustained assisting forces, mediated via a circular kinetochore coupler. A load-dependent acceleration of MT growth rates provides an explanation for the long-standing problem of synchronizing the assembly and disassembly of MTs connected to opposite spindle poles during metaphase chromosome oscillations.

P150/B154

A Model for Ftsz Treadmilling and Nucleation Based on R->T State Conformations and Gtp Hydrolysis, and Potential Application to Assembly of Microtubules.

L. Corbin, **H. P. Erickson**; Duke University Med Ctr, Durham, NC.

(A) Bacterial tubulin homolog FtsZ assembles single-stranded protofilaments (PFs) that treadmill, adding subunits at the bottom and losing them at the top. We have designed a Monte Carlo (Gillespie) model based on a transition from an R(elaxed) state, with low affinity for PF assembly, to a T(ense) state with high affinity. FtsZ monomers are mostly R, while subunits in a PF switch to T. GTP hydrolysis weakens the longitudinal affinity, but if the GDP is in the middle of the PF the T-state interfaces remain strong enough to avoid fragmentation. However, the top subunit has no subunit above it to enforce its T state, and a GDP below allows it to switch to R and rapidly dissociate. Treadmilling is powered by a GTP->GDP gradient, as GTP subunits associate at the bottom and hydrolase stochastically. Although the PF top is mostly GDP, there is a finite probability of having a GTP, which would initiate a GTP cap on top. Our model uses kinetics suggested by A. Wegner (JMB 108:139, 1976) to erode this cap and permit treadmilling to continue. The model matches treadmilling velocity, GTP turnover and PF length distribution. **(B)** Our model also provides a natural mechanism for nucleation. Monomeric FtsZ exists in a ~5000:1 R:T equilibrium, where the small fraction of T monomers serve as nuclei. R monomers bind to the bottom of a T monomer with the same kinetics as to a PF bottom. The model matches published nucleation curves. **(C)** Recently McIntosh et al (JCB 217:2691) presented cryoEM evidence that MTs flair into single PFs at both growing and shrinking ends. This suggests that subunits add by forming a single longitudinal bond at the end of a PF, a major departure from lattice models that invoke lateral bonds and cozy corners. Tubulin is known to have R and T-state conformations similar to FtsZ. We suggest that the R->T transition may allow for cooperative MT assembly at the level of single flared PFs. Lateral bonds are essential for making the MT wall, but are only formed several subunits below the PF tip, where

subunits add by forming a single longitudinal bond. This mechanism has been detailed in Biophys J 116:1-6.

P151/B155

CENP-E/kinesin-7 and KIF4A/kinesin-4 Sequentially Drive Microtubule Flux in Human Mitotic Spindles.

Y. Steblyanko[1], G. Rajendraprasad[1], M. Osswald[2], S. Eibes[1], S. Geley[3], A. Pereira[2], H. Maiato[2], **M. Barisic**[1]; [1]Danish Cancer Society, Copenhagen, DENMARK, [2]i3S, Porto, PORTUGAL, [3]Innsbruck Medical University, Innsbruck, AUSTRIA.

Mitotic spindle microtubules (MTs) in metazoans undergo poleward flux, which has been proposed to improve chromosome segregation fidelity. Despite that its presence have been observed for decades, the molecular and functional basis underlying spindle MT flux remains controversial. Here, we re-investigated several known candidates required for flux (kinesin-5/EG5, kinesin-13/KIF2A, CLASP1+2), while testing additional potential players (kinesin-12/KIF15, kinesin-7/CENP-E, kinesin-10/hKID, kinesin-4/KIF4A). We identified KIF4A as a particularly strong driver of MT-flux during late prometaphase/metaphase. This depended on its motor activity and localization on chromosomes. In agreement, expelling the chromatin from the spindle in cells undergoing mitosis with unreplicated genomes (MUGs), led to a strong reduction in flux rates, suggesting a role for chromosome arms in MT-flux generation. To examine how kinetochore (KT)-MT end-on attachments impact MT-flux, we measured flux rates in cells depleted of NDC80/HEC1. Intriguingly, MTs in these cells fluxed faster, indicating that KT-MT end-on attachments work as flux brakes, consistent with a coupled-spindle model in which fluxing non-KT MTs transmit force to KT MTs via MT-crosslinking. Testing this, we found that depletion of the MT crosslinking proteins NuMA and kinesin-14/HSET, but not PRC1, reduced MT-flux rates only when end-on attachments were established. Moreover, this resulted in asynchronous MT-flux within different spindle MT subpopulations. Thus, MT-crosslinking molecules ensure the equal distribution of MT-flux-dependent forces across the mitotic spindle. Most surprisingly, CENP-E inhibition strongly reduced MT-flux, specifically in NDC80/HEC1 depleted cells, suggesting a role in MT-flux generation before the establishment of end-on KT-MT attachments. Taken together, these data support a model in which MT-flux in early mitosis is largely driven by CENP-E, which localizes at KTs and interpolar MTs throughout mitosis. Upon chromosome congression, most of CENP-E is stripped from KTs and KIF4A cannot move the chromosomes any further due to equivalent opposite forces. Consequently, KIF4A causes chromatin-interacting MTs to flux towards the poles. KT MTs flux due to spindle MTs coupling via MT cross-linkers. Spindle length is maintained by the polymerizing and depolymerizing activities of CLASPs and KIF2A, respectively.

P152/B156

Dynamics of Microtubule Doublet Assembly.

I. Zhernov[1,2], E. Bertiaux[3], V. Hamel[3], P. Guichard[3], M. Braun[1], Z. Lansky[1]; [1]Institute of Biotechnology CAS, BIOCEV, Vestec, CZECH REPUBLIC, [2]Faculty of Mathematics and Physics, Charles University in Prague, Prague, CZECH REPUBLIC, [3]Department of Cell Biology, Sciences III, University of Geneva, Geneva, SWITZERLAND.

Microtubule doublets (MTDs) are structures found in cilia serving as scaffolding elements and double-track railways for intraflagellar transport trains. These MTDs are formed by a complete A-microtubule (A-MT) composed of 13 protofilaments and an incomplete B-microtubule (B-MT) of 10 protofilaments.

Despite the fundamental role of MTDs, the molecular mechanism governing their formation is unknown. We used a cell-free assay to demonstrate a crucial inhibitory role of the carboxyl-terminal (C-terminal) tail of tubulin in MTD assembly. Removal of the C-terminal tail of an assembled A-microtubule allowed for the nucleation of a B-microtubule on its surface. C-terminal tails of only one A-microtubule protofilament inhibited this side-to-surface tubulin interaction, which would be overcome in vivo with binding protein partners. Cryo-ET of these reconstituted MTDs showed structural similarity to the ciliary MTDs with a typical triangular outer junction.Live imaging of MTD assembly from fluorescently-labeled tubulin revealed that the B-MT nucleate on the surface of the A-MT and showed isotropic elongation in the presence of GMPCPP, a non-hydrolyzable analogue of GTP. By contrast, in the presence of GTP B-MTs' tips exhibited dynamic instability similar to normal dynamic microtubule behavior.Collectively, these data shed light on the crucial role of tubulin C-terminal tails in regulating MTDs and dynamics of B-MT nucleation and assembly.

P153/B157

CLASP Modulates the GTP-Cap Length of Plant Cortical Microtubules.

D. Thoms, **S. L. Shaw**; Indiana University, Bloomington, IN.

Flowering plants form distinct cortical microtubule array patterns in the absence of centrosomes that guide the deposition of cellulose into the cell wall. The single CLASP gene in *Arabidopsis* contains 3 tog domains, similar to human CLASP2, but lacks the SxIP EB1 binding sites. The *clasp1* mutant exhibits cell morphology defects, slow reorganization of the interphase cortical microtubule patterns, and 30% fewer growing microtubule plus ends. To determine how CLASP acts on these cortical microtubules, we imaged EB1-GFP and GFP-Tubulin in wild type and *clasp1* cells at 10 fps and applied new tracking algorithms to identify polymer growth properties. Wild type and *clasp1* microtubules both exhibit episodic pausing in *vivo*. The switch from microtubule growth to shortening (catastrophe) was preceded in wild type and mutant by pausing and exactly correlated with the processive loss of EB1-GFP marking the GTP-cap. Super-resolution imaging indicates a 30% shorter EB1-GFP distribution on *clasp1* microtubule ends compared to wild type, correlated with the faster pause-to-catastrophe times for *clasp1* microtubules. Using mean subunit assembly rates and pause-to-catastrophe times, we estimate rate constants for GTP cap subunit transitions with CLASP and without CLASP. Fluorescence recovery after photobleaching of EB1-GFP indicates a slower recovery in the absence of CLASP. Examination of microtubule nucleation and rescue events indicates that CLASP acts generally to extend the GTP cap, leading to fewer catastrophe events and a higher probability of success for nascent growing plus ends during nucleation and rescue. Our results suggest that CLASP is acting generally to increase the lifetime of microtubules without substantially altering growth rates in this natively treadmilling system.

Septin 2/6/7 Complexes Tune Microtubule Plus End Growth and EB1 Binding in a Concentration- and Filament-dependent Manner.

K. Nakos, M. Radler, E. T. Spiliotis; Drexel University, Philadelphia, PA.

Regulation of microtubule dynamics is critical for many biological functions ranging from cellular morphogenesis and intracellular transport to cell migration and accurate chromosome segregation during cell division. Septins are GTP-binding proteins that organize into higher order complexes. Septins associate with the actin and microtubule cytoskeleton and have been shown to affect MT organization-

dynamics and post-translational modifications (e.g. Acetylation, tyrosination) in various cell types, but how septins impact the dynamic instability of MTs is poorly understood. Here, we reconstituted in vitro MT dynamics using total internal reflection fluorescence (TIRF) microscopy in the presence of recombinant SEPT2/6/7 complexes which comprise the minimal subunits of septin heteromers. We found that SEPT2/6/7 has a biphasic concentration-dependent effect on MT dynamics. Lower concentrations of SEPT2/6/7 enhance MT plus end growth and elongation, while higher and intermediate concentrations inhibit and pause plus end growth, respectively. We show that SEPT2/6/7 associates with higher preference to GTP- over GDP-bound MT lattice, and competes with End-Binding protein 1 (EB1) for binding to GTPγS-stabilized MTs, which mimic the EB1-preferred GDP-Pi state of polymerized tubulin. Notably, SEPT2/6/7 inhibits MT plus end binding and tracking of EB1 in cis by binding to the MT lattice and in trans when MT plus ends come in contact with SEPT2/6/7 filaments. SEPT2/6/7 filaments are more potent than actin filaments in pausing MT plus ends and dissociating EB1 from MT plus end tips in vitro as well as in cultured rat embryonic hippocampal neurons. Collectively, our data demonstrate that SEPT2/6/7 complexes and filaments can directly regulate MT plus end dynamics and the binding of plus end-binding proteins, and thereby promote the capture and invasion of MTs at intracellular sites or structures of septin enrichment.

P155/B159

Multi-scale Microrheology Using Fluctuating Semiflexible Filaments as Stealth Probes.

K. Nishi[1], S. Raja[1], F. C. MacKintosh[2], C. F. Schmidt[1]; [1]Duke University, Durham, NC, [2]Rice Uiversity, Houston, TX.

The cytoskeleton governs cellular dynamics and provides structural support. These functions rely on the complex mechanical properties of the cytoskeleton, which strongly depend on the length scale. To characterize such scale-dependent mechanical properties in viscoelastic media, we propose a new method of microrheology using semi-flexible filaments. Such probes are much less invasive than the often-used micrometer-sized beads. By tracking multiple transverse bending modes we can simultaneously determine the micromechanical response of the medium on multiple length scales. We use single-walled carbon nanotubes (SWNT) as probes that can be accurately imaged based on their non-photobleaching fluorescence. We find that the viscoelastic properties of proof-of-concept test samples, sugar solutions and polymer solutions, measured in this way are in good agreement with those measured by conventional micro/macrorheology.

Direct Measurement of Force Production by Microtubules Disassembling in the Presence of Stabilizing and Destabilizing Agents.

H. Kim[1], L. Murray[1], E. A. Geyer[2], L. M. Rice[2], C. L. Asbury[1]; [1]University of Washington, Seattle, WA, [2]UT Southwestern Medical Center, Dallas, TX.

Microtubule-based pulling forces are the basis for chromosome movements during mitosis. A popular view is that strain energy released during microtubule disassembly, when straightened protofilaments in the lattice curl outwardly to form “ram’s horns” at disassembling plus-ends, imparts a significant amount of mechanical force crucial for chromosome movement. Additionally, this conformational wave of curling protofilaments is implicated in helping kinetochores to remain associated with disassembling microtubule tips. However, the fundamental mechanisms that govern the extent of protofilament

curling at disassembling tips remain unclear, and whether these curls affect kinetochore function has never been proven. Using a feedback-controlled laser trap, we are measuring the nanometer-scale displacements of microbeads as they are pushed laterally by curling protofilaments during disassembly. Previous work suggests that the extent of movement in this 'wave' assay might depend on how the bead is tethered to the microtubule wall. Therefore we are testing several different tethering methods, including a direct biotin-streptavidin linker, an anti-His antibody bound to 6xHis on the C-terminus of β-tubulin, and a DNA-based linker. To explore the relationship between wave energy, disassembly speed, and tip conformation, we are adding agents known to either speed disassembly and enhance protofilament curling (e.g., destabilizers such as Mg^{2+}, and MCAK) or slow disassembly and decrease curling (e.g., stabilizers such as taxol, or DZ-2384). This work will reveal how changes in microtubule disassembly conditions alter conformational wave energy, and will provide a first step toward understanding how wave energy influences kinetochore function.

P157/B161

Parameter Space Compression of Microtubule Dynamic Instability.

C. Hsu, **G. J. Brouhard**, P. Francois; McGill University, Montreal, QC, CANADA.

Physical models of biological systems can become difficult to interpret when they have a large number of parameters. But the models themselves actually depend on (i.e. Are sensitive to) only a subset of those parameters. Rigorously identifying this subset of "stiff" parameters has been made possible by the development of parameter space compression (PSC). However, PSC has only been applied to analytically-solvable physical models. We have generalized this powerful method by developing a numerical approach to PSC that can be applied to any computational model. We validated our method against analytically-solvable models of random walk with drift and protein production and degradation. We then applied our method to an active area of biophysics research, namely to a simple computational model of microtubule dynamic instability. Such models have become increasingly complex, perhaps unnecessarily. By adding two new parameters that account for prominent structural features of microtubules, we identify one that can be "compressed away" (the "seam" in the microtubule) and another that is essential to model performance (the "tapering" of microtubule ends). Furthermore, we show that the microtubule model has an underlying, low-dimensional structure that explains the vast majority of our experimental data. We argue that numerical PSC can identify the low-dimensional structure of any computational model in biophysics. The low-dimensional structure of a model is easier to interpret and identifies the mechanisms and experiments that best characterize the system.

P158/B162

Microtubules Are Necessary for Proper Reticulon Localization during Mitosis.

U. Diaz[1,2], Z. J. Bergman[2], A. Edington[2], M. D. E. Cruz[2], B. Johnson[2], W. Marshall[1], B. Riggs[2]; [1]University of California San Francisco, San Francisco, CA, [2]San Francisco State University, San Francisco, CA.

During mitosis, the structure of the Endoplasmic Reticulum (ER) displays dramatic reorganization and remodeling, however the mechanism driving these changes is poorly understood. Recently, the Reticulon family of ER shaping proteins has been identified as possible factors to promote these drastic changes in ER morphology. Here, we examined the role of cytoskeletal factors involved in the dynamics of a *Drosophila* Reticulon, Reticulon-like 1 (Rtnl1) during mitosis in the early embryo. At prometaphase, Rtnl1 localizes to the spindle poles just prior to the bulk of ER localization suggesting a role in

recruitment. Using precise temporal injections of cytoskeletal inhibitors in the early syncytial *Drosophila* embryo, we show that microtubules, not microfilaments are necessary for proper Rtnl1 localization during mitosis. Lastly, we show that astral microtubules are necessary for Rtnl1 localization to spindle poles early in mitosis and independently of the minus-end directed motor protein Dynein. This work highlights the role of the microtubule cytoskeleton in Rtnl1 localization to spindles during mitosis and sheds light on a pathway towards inheritance of the ER.

Investigating the Dynamics of Chromatin-driven Mitotic Spindle Assembly in *Drosophila Melanogaster*.

J. P. Marks[1], D. Hayward[2], K. Heesom[3], J. Wakefield[4]; [1]University of Exeter, Exeter, UNITED KINGDOM, [2]Sir WIlliam Dunn School of Pathology, University of Oxford, Oxford, UNITED KINGDOM, [3]Proteomics Facility, Faculty of Medical and Veterinary Sciences, University of Bristol, Bristol, UNITED KINGDOM, [4]Biosciences, College of Life and Environmental Sciences, University of Exeter, Exeter, UNITED KINGDOM.

Mitosis is the process by which duplicated chromosomes are separated between two daughter nuclei. This is facilitated by the mitotic spindle, a bipolar scaffold of microtubules (MTs) which organises and segregates the chromosomes. The formation of a robust mitotic spindle is important for the accurate segregation of chromosomes, and as such, MTs are generated in several different ways. Generally, the mitotic spindle is thought to be generated predominantly from centrosomal MT nucleation; however, abrogation of centrosomal MT nucleation results in a mitotic spindle generated predominantly from chromatin. Chromatin-driven mitotic spindle formation is known to rely on a RanGTP gradient generated in the vicinity of chromatin, and a number of spindle assembly factors (SAFs), including the Augmin (HAUS) complex and Mars (Hepatoma upregulated protein). This project aims to further elucidate the roles of SAFs in chromatin-driven mitotic spindle assembly using the *Drosophila melanogaster* syncytial blastoderm.

P160/B164

Microtubule Growth Rates Are Sensitive to Changes in Microtubule Plus-end Density.

Z. Geisterfer[1], D. Zhu[1], A. Milunovic´-Jevtic´[1,2], J. Gatlin[1,2]; [1]Department of Molecular Biology, University of Wyoming, Laramie, WY, [2]Cell Organization & Division Group, Marine Biological Laboratory, Woods Hole, MA.

Microtubules (MTs) are inherently dynamic filamentous polymers that can stochastically switch between periods of growth (via tubulin subunit addition) and periods of shortening (via tubulin subunit subtraction). The process of MT plus-end growth has been shown to be important in establishing the steady-state dimensions of large MT assemblies such as the mitotic spindle (Reber et al., 2013; Milunovic-Jevtic et al., 2018; Lacroix et al., 2018), yet the fundamental mechanisms that underlie the spatial and temporal regulation of individual MT growth rates within the cell are still being characterized. Previous investigations into the regulation of MT growth rates were focused primarily on the molecular identities of key microtubule associated proteins (MAPs) and the protein composition of the cytosol. As such, these studies largely neglected the role of microtubule spatial density and growing MT plus-end competition in regulating MT growth rates. Here, we use fluorescence microscopy and geometrically confined *Xenopus* cell-free extracts to elucidate a previously un-characterized role for MT

plus-end density in regulating MT growth rates. Our analyses revealed that global MT growth rates in confined cytoplasm decrease as MT plus-end density increases. Moreover, we found that spatial differences in MT plus-end densities can impart local changes to MT growth rates within a contiguous cytoplasm. We speculate that these density-dependent effects likely exist due to limitations in the diffusive rate of key growth promoting factors (i.e. XMAP215, +TIP proteins). As a result, a growing MT system can experience a global depletion of components, while an individual growing MT end experiences a local protein gradient dictated by the presence and proximity of other growing MT plus-ends. These data suggest that individual MT growing ends compete for a limited pool of structural components or growth promoting factors.

Assembly and Disassembly of Cilia/Flagella

Cilia Development in Zebrafish Organ of Asymmetry.

J. Manikas, L. Rathbun, J. Freshour, H. Hehnly; Syracuse University, Syracuse, NY.

In vitro studies have identified two methods for ciliogenesis. The first, the centrosome/basal body constructs a cilium in the cell body where it then fuses with the plasma membrane. The second, the centrosome/basal body docks at the plasma membrane where it then assembles a cilium. The goal of our studies is to identify during in *vivo* organogenesis how cells construct a cilium. We have chosen to examine Kupffer's Vesicle (KV) development of *Danio rerio* (zebrafish) due to the transparency of the zebrafish embryo for live-cell 4-dimensional imaging. KV is an organ of asymmetry that is required to place visceral and abdominal organs with respect to the two main body axes. KV development requires cells to self-assemble into a rosette where cells then establish apicobasal polarity termed apical clustering. The rosette then transitions into a sphere with a fluid filled lumen. At this stage, cilia are projected into the lumen. Our studies have identified that early on in KV development, before a lumen has formed, cilia are being constructed in the cell volume (100%). In later stages of KV development (lumen expansion), we only see 1.3% of cilia still in the cell volume where the remaining population is projected into the lumen. These studies suggest that cilia first form in the cell body and then protrude into the extracellular space once a lumen is formed. To further identify the molecular mechanisms required to generate KV cilia we are analyzing the role of apically localized actin and the small GTPases Rab11 and Rab8. We propose a model that after the cilia is constructed and surrounded by a ciliary membrane cap, actin is organized along the apical membrane where it can generate tension to regulate when a cilium should protrude into the lumen. Based on the literature and our preliminary studies, Rab11-endosomes likely contribute to the formation of a ciliary cap and the recruitment of Rab8 that is required for cilia elongation. In efforts to further understand the role of Rab11 and Rab8 in ciliogenesis, we are utilizing an optogenetic approach to disrupt either Rab11 or Rab8 and quantify its effect on cilia development and maturation in vivo.

P162/B167

Conventional Actin Is Required for Sensing Deciliation Or Initial Execution of the Ciliary Re-assembly Program Post-deciliation In*Chlamydomonas Reinhardtii*.

N. E. Rosenthal, P. Avasthi; University of Kansas Medical Center, Department of an atomy and Cell Biology, Kansas City, KS.

Chlamydomonas reinhardtii, a biflagellate unicellular green alga, is a powerful model for understanding human disease as its cilia closely resemble those in human cells.*Chlamydomonas* has two actin genes coding for a conventional actin (IDA5) and a novel actin-like protein (NAP1). Our previous studies show that after deciliation through acidic pH shock, cilia can be fully reassembled when either actin is present. However, when both actins are disrupted (by depolymerizing IDA5 with latrunculin B, LatB, in the *nap1* mutant background), ciliary reassembly is inhibited, and cilia do not reach full length. This is due to multiple roles for actins including in the transport post-Golgi vesicles. Surprisingly, our new results show that total actin disruption during only the 10 minute period prior to and during deciliation also causes significant ciliary assembly defects. Further, impaired ciliary assembly is robust in both *nap1* mutants and wild-type cells with extended LatB pre-treatment (a condition in which NAP1 is typically upregulated and can rescue most IDA5 phenotypes). This indicates that NAP1 upregulation cannot compensate for actin functions before/during deciliation. Prior work in *Chlamydomonas* suggests deciliation is followed by a signal to the cell that it needs to upregulate the production of ciliary proteins to begin to rebuild cilia. When we acutely disrupt both actins only during the short period prior to and during deciliation, cilia behave similarly to cells treated with the protein synthesis inhibitor cycloheximide, which prevents cells from incorporating any new proteins that would have been synthesized as a result of deciliation. Our findings suggest that the presence of actin is somehow necessary for the cilia to either propagate the deciliation signal, or to initiate the subsequent process of ciliary protein upregulation.

Speed and Diffusion of Kinesin-2 Are Competing Limiting Factors in Flagellar Length Control Model.

N. L. Hendel[1], R. Ma[2], H. Qin[3], W. F. Marshall[1]; [1]UCSF, San Francisco, CA, [2]Yale University, New Haven, CT, [3]Texas A&M University, College Station, TX.

Flagellar length control in Chlamydomonas is a tractable model system for studying the general question of organelle size regulation. We have previously proposed that diffusive return of the kinesin motor that powers intraflagellar transport can play a key role in length regulation. Here we explore how the motor speed and diffusion coefficient for the return of kinesin-2 affect flagellar growth kinetics. We find that the system can exist in two distinct regimes, one dominated by motor speed and one by diffusion coefficient. Depending on length, a flagellum can switch between these regimes. Our results indicate that mutations can affect length in distinct ways. We discuss our theory's implication for flagellar growth influenced by beating and provide possible explanations for the experimental observation that a beating flagellum is usually longer than its immotile mutant. These results demonstrate how our simple model can suggest explanations for mutant phenotypes.

P164/B169

Analysis of Protein Dynamics in Motile Cilia of Mouse Tracheal Epithelial Cells Using High-resolution Live Imaging.

C. McKenzie[1], J. Kuiken[1], J. Liu[2], I. Chandrasekar[1], **L. Lee**[1]; [1]Sanford Research, Sioux Falls, SD, [2]Indiana University – Purdue University Indianapolis, Indianapolis, IN.

Dysfunction of motile cilia results in defects in fluid clearance and the pediatric syndrome primary ciliary dyskinesia (PCD). Motile cilia possess a 9+2 microtubule structure with nine outer microtubule doublets surrounding a central pair apparatus. While the importance of the motile cilia in human health is clear, the ability to study and understand protein dynamics in mammalian motile cilia has been limited, largely based on availability of useful tools and feasible strategies. In this study, we demonstrate a novel application of high-resolution, live confocal imaging to analyze ciliary protein trafficking and dynamics in ciliated mouse tracheal epithelial cells (mTECs). The mTECs are cultured at an air-liquid interface to enable optimal ciliogenesis, and GFP-tagged ciliary proteins are over-expressed using a lentiviral system. We have performed live single molecule imaging of GFP-tagged intraflagellar transport protein 52 (IFT52) in mTECs from wild type mice and a PCD mouse model with a mutation in the central pair apparatus gene *CFAP54*. Quantitative analysis by single molecule tracking and image correlation spectroscopy enables an in-depth interrogation of protein dynamics within the intraflagellar transport system of mammalian motile cilia. This study establishes a powerful platform for analysis of protein dynamics to elucidate the cellular mechanisms underlying mammalian motile cilia and PCD pathogenesis.

P165/B170

Microtubule Inner Proteins Weave into the Doublet Microtubule Tubulin Lattice.

M. Ichikawa[1], A. Khalifa[1], S. Kubo[2], K. Basu[1], D. Dai[1], M. Maghrebi[1], J. Vargas[1], **K. Bui**[1]; [1]McGill University, Montreal, QC, CANADA, [2]Kyoto University, Kyoto, JAPAN.

As the hair-like protrusions that beat at high frequencies to propel a cell or move fluid around the cell, cilia are both structurally flexible and stable. Little is known about how cilia are able to maintain its stability during high-frequency bending cycles. Cilia are composed of radially bundled doublet microtubules. The doublet microtubule is composed of a 13-protofilament A-tubule, a partial 10-protofilament B-tubule and microtubule inner proteins (MIPs) inside the tubulin lattice. In contrast to the cytoplasmic microtubule, the doublet microtubule does not show any dynamic instability. This prompts the question of how the MIPs influence the doublet microtubule stability and rigidity. The objective of the study is to uncover the molecular architecture of the tubulin lattice of the doublet microtubule and the effect of the MIPs on the tubulin lattice. Using single particle cryo-electron microscopy, we obtained the structure of the Tetrahymena doublet microtubules at 4.3 an gstrom resolution. Remarkably, the tubulin lattice of the doublet microtubule has a complex pattern in dimer distance and curvatures within the 48-nm repeat. This is due to an intricate network of MIPs, weaving into the tubulin lattice. In particular, the filamentous MIPs at the protofilament ribbon area insert itself into the interdimer interface every two tubulin dimers, leading to a distinct bimodal pattern of short and long dimer distances every 16-nm. The filamentous MIPs also form a head-to-tail interaction consecutively to form long chains along the protofilament ribbon and consequently, increase the stability and elasticity of the doublet. These results suggest that there is a complex interplay between

the MIPs and the tubulin lattice in the doublet microtubule. In addition, the doublet microtubule is mechanically stressed. This stress could be tweaked by the MIPs in the regulation of ciliary functions.

P166/B171

Outer Arm Dyneins Are Locked in a Closed State by Novel Factors Prior to Delivery to the Ciliary Axoneme.

G. R. Mali, A. P. Carter; Medical Research Council, Laboratory of Molecular Biology, Cambridge, UNITED KINGDOM.

Cilia motility is vital in organisms ranging from protozoa to humans. Key drivers of this beating movement are outer arm dyneins (ODAs). Here we identify two novel factors that bind newly synthesised ODAs prior to their delivery to the axoneme. We purified ODAs from cell bodies of de-ciliated *Tetrahymena thermophila*. Negative stain electron microscopy showed these ODAs are locked in a closed conformation in contrast to the open bouquet of ODAs purified from axonemes. Mass spectrometry identified two proteins (Q22YU3 and Q22MS1) that co-purify with cell body ODAs. We show that incubation with recombinant Q22YU3 and Q22MS1 is sufficient to induce closure of the ODA bouquet. We propose that closed ODAs represent an inhibited pre-assembled state. The newly discovered proteins provide a molecular explanation for how ODAs are prevented from moving on microtubules in the cell body prior to their delivery to the ciliary axoneme.

P167/B172

Testing the Ion-current Model of Flagellar Length-sensing.

H. Ishikawa[1,2], J. Moore[1,3], D. Diener[4], M. Delling[1], W. Marshall[1,2]; [1]University of California, San Francisco, San Francisco, CA, [2]Center for Cellular Construction, San Francisco, CA, [3]Kenyon College, Gambier, OH, [4]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, GERMANY.

The mechanism by which cells control size of organelles is a fundamental question in cell biology about which very little is known, in part because the complexity of many organelles makes their size control mechanisms difficult to study. Eukaryotic cilia and flagella are microtubule-based organelles whose relatively simple structure makes them ideal for investigating the mechanisms of size regulation. Flagella are constructed and maintained via an active transport process called intraflagellar transport (IFT). Since no protein synthesis occurs in the flagellum, new materials must be injected into the flagellum by a process called IFT injection. The rate of IFT injection has been shown to negatively correlate with flagellar length. This length-dependent IFT injection rate suggests that the cell has some method for measuring its flagella. However, it remains unknown how the cell measures the length of its flagella and controls IFT injection. Here we experimentally tested one theoretical model of flagellar length-sensing: the ion-current model. This model posits that there is a uniform distribution of calcium channels along the flagellum, and that the calcium current from the flagellum into the cell body increases linearly with flagellar length. In this model, the cell uses the calcium current to negatively regulate IFT injection. We used quantitative total-internal-reflection-fluorescence (TIRF) microscopy to measure the calcium level inside of *Chlamydomonas* flagella using a genetically encoded calcium indicator. The level of calcium inside of flagella was weakly correlated with the length of flagella. We then quantified IFT injection in wild-type and calcium-deficient flagella using TIRF microscopy. We found that the amount of IFT injection was reduced and decoupled from the length in calcium-deficient flagella. Thus, while calcium may be important for regulating IFT, it is not a simple negative regulator of IFT injection and could not

form the basis of a stable length control system. This observation does not support the ion-current model.

P168/B173

High-resolution Cryo-em Structure of the Decorated Ciliary Doublet Microtubule.

M. Ma[1], M. Stoyanova[1], G. Rademacher[2], S. Dutcher[1], A. Brown[2], **R. Zhang**[1]; [1]Washington University in St Louis, St. Louis, MO, [2]Harvard Medical School, Boston, MA.

Cilia are hair-like organelles present on the surface of almost every eukaryotic cell and are responsible for cellular motility, fluid flow and sensory perception including sight, hearing and smell. At the heart of each cilium is a highly conserved structure called the axoneme that spans the entire length of the organelle. It is the largest protein complex in many organisms and can be many times larger than a cell body. Unlike bacterial flagella, which consist of thousands of copies of a single protein, the axoneme is made from hundreds of different proteins. Scaffolding the axoneme are 9 doublet microtubules that are essential for the architectural rigidity and motility of cilia and provide a track for intraflagellar transport. Bound periodically along the length of each doublet microtubule are a variety of microtubule-associated proteins and complexes that decorate the external and luminal faces of the microtubules. These proteins remain in register along the entire length of the doublet microtubule. Furthermore, all doublets within an axoneme are in coherent register with one another. An y breakdown of this coherence leads to impaired motility. How periodicity is established, maintained, and synchronized for such large structures has been a long-standing mystery. In this study we determined the high-resolution structure of the 96-nm repeat unit of a native, fully decorated doublet microtubule and build a near-complete atomic model for its internal 48-nm repeat. The structure is one of the most complex ever solved by cryo-EM with 40 different proteins arranged into ~450 chains. Our structure demonstrates how these proteins establish the unique architecture of doublet microtubules, maintain coherent periodicities along the axoneme, and stabilize the microtubules against the repeated mechanical stress induced by ciliary motility. The structure will serve as a reference for interpreting genetic, biochemical, and physiological data from different cell types and for understanding the etiology of human ciliopathies.

P169/B174

Localization of FAP93 and PP2A at the Proximal End of *Chlamydomonas* Ciliary Axonemes.

J. Hwang[1], H. Yanagisawa[2], E. L. Hunter[1], K. C. Davis[1], R. Bower[3], M. E. Porter[3], W. S. Sale[1], **L. M. Alford**[4]; [1]Emory University, Atlanta, GA, [2]The University of Tokyo, Tokyo, JAPAN, [3]University of Minnesota, Minneapolis, MN, [4]Oglethorpe University, Brookhaven, GA.

In most motile cilia, bending is initiated from the proximal end of the axoneme. Additionally, the proximal axoneme is also relatively stable compared to the distal axoneme (Alford et al., 2016). However, we do not have a detailed understanding of the specialized proteins localized to the proximal axoneme. Using *Chlamydomonas*, we performed iTRAQ proteomics analysis to quantitatively compare protein enrichment in short (~2µm) versus full-length (~11µm) axonemes. We predicted that specialized proteins localized at the proximal, or distal, axoneme will be enriched in the short axonemes (see Satish Tammana et al., 2013). Short axonemes were isolated from regenerating cilia {Hunter et al. 2016} or from the *pf9-2; pf28* double mutant which grows axonemes ~2-4µm long (Porter et al., 1992). We detected over 200 proteins enriched ≥1.4-fold in short axonemes. Consistent with previous reports, the minor dynein heavy chains (DHC3, DHC4, and DHC11) known to localize to the proximal axoneme

(Piperno, 1991; Yagi et al., 2009) and the tip protein FAP256 (CEP104) (Satish Tammana et al., 2013) were enriched in short axonemes. Our current focus is on two proteins the iTRAQ analysis revealed are enriched in short axonemes, FAP93 and PP2A. FAP93, a protein of unknown function, is enriched in the short *pf9-2; pf28* double mutant axonemes. Consistently, immunoblots show enrichment of FAP93 in short axonemes and immunofluorescence staining of FAP93 shows localization at the proximal axoneme. We are currently examining dynein assembly and stability of axonemes in newly isolated *fap93* null mutants. Unexpectedly, PP2A C and B subunits are enriched in both regenerating and *pf9-2; pf28* short axonemes. Consistent with this hypothesis, the *Chlamydomonas* motility mutant *pf4*, defective in the gene that encodes the PP2A B-subunit, has decreased swimming velocity {Elam et al., 2011}. The swimming phenotype was confirmed in newly isolated *pf4* null alleles. Immunoblot analysis also showed enrichment of PP2A-C and B subunits in short axonemes and immunofluorescence staining of PP2A3-HA (IMP3-HA, Lin et al., 2013) showed enriched localization at the proximal end of the axoneme. We postulate that PP2A, localized to the proximal 2µm of the axoneme, is a candidate component for regulation of ciliary bending.

P170/B175

Rhythmic Pulsation of Flagellar Axonemal Protein Pools in the Algal Cell Body.

Y. Liu[1], B. M. Wills[2], X. Zhu[3], **P. Yang**[3]; [1]UC San Francisco, San Francisco, CA, [2]Medical College of Wisconsin, Milwaukee, WI, [3]Marquette University, Milwaukee, WI.

Trafficking into cilia and flagella through the gated entrance near the basal body (BB) entails elaborate mechanisms, including the motor-driven intraflagellar transport (IFT). Trafficking-related anomalies account for many congenital disorders. To elucidate upstream events, this study illuminated two types of flagellar cytoskeletal proteins in live alga Chlamydomonas. IFT-delivered proteins were enriched at the exclusion zone underneath the BBs where IFT trains congregated. This area was dimmer than flagella, and the intensity was inversely related to flagella lengths. Interestingly, this area pulsated rhythmically. In contrast, the IFT-independent FAP20, which bound to microtubule doublet junction - was enriched in the nucleus. Nonetheless, the nuclear area also pulsated, pushing fluorescent FAP20 toward the flagellar entrance via straightforward or meandering paths but bypassing the exclusion zone. Inverse relationship of osmolarity with pulsation frequency and flagellar generation suggested the involvement of the adjacent contractile vacuoles. In addition, both proteins displayed an array of patterns in the cytosol, suggesting regulated vesicular associations. These observations shed light on multiple long-standing questions on ciliogenesis.

P171/B176

Ift Trains Fragment into 'Carts' of IFT-A, -B, and Dynein at the Ciliary Tip.

J. L. Wingfield[1], I. Mengoni[1], P. Liu[1], J. Dai[1], Y. Hou[2], W. Zhao[2], G. B. Witman[2], K. Lechtreck[1]; [1]Department of Cellular Biology, University of Georgia, Athens, GA, [2]Department of Cell and Developmental Biology, University of Massachusetts Medical School, Worcester, MA.

Intraflagellar transport (IFT) trains carry building blocks from the cell body into cilia. These trains are assembled at the ciliary base, move by anterograde IFT to the flagellar tip and return by retrograde IFT to the cell body (Wingfield et al. 2017). In *C. reinhardtii*, the anterograde trains possess layers of IFT-A, IFT-B and IFT dynein particles with distinct periodicities whereas the retrograde trains are more amorphous (Jordan et al. 2018). The remodeling of trains at the ciliary tip involves fragmentation of the

anterograde trains (Chien et al. 2017). However, this study is based on IFT dynein and the IFT-B1 protein IFT27-GFP. Thus, the degree of train fragmentation, e.g., into "IFT carts" consisting of IFT-A and B or into IFT-A, B1 and B2 subcomplexes or into individual IFT proteins, remains unknown. Understanding of this reorganization could shed light on the mechanisms of cargo unloading and IFT dynein activation at the tip. Here, we analyzed IFT dynamics at the ciliary tip utilizing fluorescent protein-tagged IFT-A, IFT-B1, IFT-B2, and IFT motors subunits. All IFT proteins dwell at the ciliary tip for ~2s and material from one anterograde train is distributed onto several retrograde trains. We estimate that the IFT pool at the tip correspond to 3-5 anterograde trains based off of photo-bleaching experiments. Two-color imaging of IFT140-sfGFP and IFT54-mScarlet indicates that IFT-A and B remain together during the reorganization. IFT-A and B proteins continued to travel together in BBS4-deficient cilia revealing that the BBSome is not critical for A-B association in *C. reinhardtii.* While also dwelling for ~2s, BBS4-GFP mostly diffused at the ciliary tip rather than being stationary as the IFT proteins suggesting that it is released from IFT trains. FRAP analysis of retrograde IFT at the tip revealed that IFT54-mScarlet and the IFT dynein subunit D1bLIC-GFP mostly remained together during turnaround Our data support a model of IFT turnaround in which anterograde trains fragment into carts or short strings of carts while IFT-A, B and IFT dynein remain associated.

P172/B177

Biological Noise in the *Chlamydomonas* Length Control System.

D. Bauer, K. Wemmer, W. Marshall; University of California - San Francisco, San Francisco, CA.

How cells control the size of their organelles is a long-standing biological question. Furthermore, to what extent are organelles subject to noise? to answer these questions, we investigate noise in *Chlamydomonas* flagellar length control. Flagella represent the ideal organelle to study this question, as they have they are essentially one dimensional, so changes in length are unambiguous and can be represented by a single number. We find that *Chlamydomonas* flagellar lengths vary significantly due to intrinsic fluctuations within the flagella and extrinsic noise that varies between cells. Compared to cells with equal length flagella, cells with different length flagella are worse at swimming, but better at gliding, suggesting that there may be evolutionary pressure to tune intrinsic noise in length. Our results show that noise exists on the level of organelles which can affect cellular function.

P173/B178

Mechanistic Insight into Ciliary Signaling Regulation through Map Kinases.

L. L. Dougherty, S. Dutta, P. Avasthi; University of Kansas Medical Ctr, Kansas City, KS.

Ciliary length and regulation are dictated by intraflagellar transport (IFT) which transports building materials into cilia to regulate assembly. Recent research has revealed multiple molecular targets in the Mitogen Activated Protein Kinase (MAPK) pathway that regulate ciliary length in many different types of cells from photoreceptors to *C. elegans* sensory neuron cilia. However, the mechanism that connects how MAPK regulates this function is unclear. Previously we have found that BCI, [(E)-2-benzylidine-3-(cyclohexylamino)-2,3-dihydro-1H-inden-1-one], a vertebrate MAP Kinase Phosphatase 3 inhibitor, increases phosphorylated MAPK, shortens flagella, and prevents regeneration of full-length flagella in *Chlamydomonas reinhardtii*. Here we show that BCI also prevents the GFP-tagged heterotrimeric kinesin II subunit, KAP, from entering into the cilia. Interestingly, its recruitment to the basal bodies remains unaffected even during regeneration following pH shock. This suggests a defect in protein entry that

may be the cause for shortened flagella. After also observing changes in localization of the transition zone marker, NPHP4, we show that normal NPHP4-HAC localization is lost with increasing concentrations of BCI. These results hint at a mechanism for MAPK signaling as it relates to ciliary assembly through restriction of ciliary protein gating.

P174/B179

Actin Dysregulation in *Chlamydomonas Reinhardtii* Lacking LF5p.

C. E. Villanueva, P. Avasthi; University of Kansas Medical Center, Kansas City, KS.

Previous research by Lai-Wa Tam et al. has shown that Long Flagella 5 protein (LF5p) regulates cilia length in *Chlamydomonas reinhardtii* with mutants lacking this protein (*lf5-2)* having cilia that are about 1.5x times longer than normal. The kinase domain of LF5p has high protein homology to human cyclin-dependent kinase-like kinase 5 (CDKL5), which has been shown to interact with Rac1, a critical regulator of actin. LF5p has been shown to localize to the proximal region of cilia close to the region where filamentous actin is localized. *Chlamydomonas* contains two actin genes: conventional (IDA5) and a novel actin-like protein (NAP1). Based on the interaction that CDKL5 has with Rac1 and the localization of CDKL5-like LF5p, we hypothesize that LF5p may regulate *Chlamydomonas* actins. Further, given our previously identified roles for filamentous actin in ciliary assembly and maintenance, LF5p-associated actin dysregulation may account for the length phenotype observed in *lf5-2* mutants. While mid-cell actin is undisturbed in *lf5-2* mutants, we find actin-dependent phenotypes in the absence of LF5p. We find that *lf5-2* mutants are unable to successfully form fertilization tubules, which are IDA5 dependent filamentous actin-rich structures formed in gametes. The inability to form these structures suggests a potential IDA5 actin dysregulation when LF5p is absent from cells. In addition to this, we previously found that cells treated with actin depolymerizing Latrunculin B (Lat B) require the activity of NAP1 to assemble their cilia to full length following severing. During the NAP1-dependent assembly phase, Lat B treated *lf5-2* mutants regenerate their cilia much more slowly compared to the Lat B treated controls. We have also previously shown that disruption of actin filaments results in disrupted transition zones at the base of cilia and impaired protein incorporation in cilia. *lf5*-2 mutants have been shown (Lai-Wa Tam et al. 2012) to regenerate their cilia more slowly compared to WT cells under normal conditions. Our data showing actin dysregulation in *lf5-2* mutants may indicate that the slow regeneration of these mutants could be caused by an actin defect.

P175/B180

Microtubule Inner Protein (mip) Identification in *Tetrahymena Thermophila*.

A. Fabritius[1], S. Li[2], B. Bayless[3], M. Winey[1]; [1]University of California, Davis, Davis, CA, [2]UCSF, San Francisco, CA, [3]Santa Clara University, Santa Clara, CA.

Modern advances in Cryo-ET show that some stable microtubules contain microtubule inner proteins (MIPs), which may aid in maintaining structural and functional integrity. Recently, RIB72A and RIB72B were identified as MIPs in the motile cilia of Tetrahymena thermophila. Loss of these proteins leads to ciliary defects and loss of multiple densities inside the axoneme microtubules. Mass spectrometry of the RIB72A/B double knockout strains led to identification of additional MIP candidate proteins. We are analyzing these candidate MIPs using cell biology and Cryo-ET to expand our knowledge of the identities, structures, and functions of the lumenal meshwork of proteins inside of microtubules.

P176/B181

Fap20 Localizes to Motile Cilia Doublet Microtubules and Is Necessary for Ciliary Function.

E. Martinez[1], M. Winey[2], B. Bayless[1]; [1]Santa Clara University, Santa Clara, CA, [2]University of California, Davis, Davis, CA.

Motile cilia are hair-like cellular appendages that undulate to move extracellular fluid. In humans, motile cilia move cerebrospinal fluid, clear mucus from the airway, and move eggs down the Fallopian tube. As such, defects in motile cilia beating cause severe human disorders like hydrocephalus, respiratory defects, and female infertility. The ability of motile cilia to beat relies heavily on its axoneme structure. Cilia axonemes are composed of stable doublet microtubules. How these unique doublet microtubules are built and stabilized is poorly understood. Cryo-electron tomography (Cryo-ET) has been used to investigate the structure of the doublet microtubules. From these studies densities on the inside of these doublet microtubules were identified, called microtubule inner proteins (MIPs). Recently Rib 72 has been identified as a MIP and is necessary for the localization of the majority of a-tubule MIPs. We used mass spectrometry to identify the missing a-tubule MIPs. From the mass spectrometry we identified Fap20 as a candidate MIP. In *Chlamydomonas,* Fap20 localizes to the inner junction of the a-tubule. We find that *Tetrahymena* Fap20, expressed under its native promoter, localizes to motile cilia. Genomic knock down of Fap20 results in reduced swim speed of the organism, which is indicative of ciliary beating defects. Our results highlight the interdependence of ciliary structure and function.

P177/B182

Fap67 Localizes to Motile Cilia Doublet Microtubules and Plays a Role in Ciliary Function.

F. Navarro[1], M. Winey[2], B. Bayless[1]; [1]Santa Clara University, Santa Clara, CA, [2]University of California, Davis, Davis, CA.

Motile cilia are microtubule-based, cellular appendages responsible for directed extracellular fluid flow. Motile cilia are present within the human brain, lungs, and female reproductive tract. Defects in motile cilia function have dire and wide-ranging implications for human health and disease, with defects ranging from epilepsy to infertility. Cilia are comprised of an axoneme consisting of modified doublet microtubules. The formation and structure of doublet microtubules is necessary for motile cilia function. Cryo-electron microscopy and tomography show that doublet microtubules are decorated with lumenal proteins called microtubule inner proteins (MIPs). These MIPs are essential for stabilizing the doublet microtubule structure and overall function of motile cilia, however, the role and identity of all MIPs have yet to be discovered. Mass spectrometry identifies *Tetrahymena* Fap67 as a potential ciliary MIP. Endogenously expressed Fap67 localizes to motile cilia. Overexpression of Fap67 fragments reveals that Fap67 localization is dependent on its N-terminal. Fap67 knock down strains show reduced swimming speeds, indicative of disrupted ciliary beating. Our results suggest that Fap67 is vital for proper ciliary function.

Centrosome Assembly and Functions 1

P178/B184

PCMD-1 Regulates Centrosome Assembly in *C.elegans*.

L. Stenzel[1], A. C. Erpf[2], T. Mikeladze-Dvali[1]; [1]LMU Munich, Munich, GERMANY, [2]Lunenfeld-Tanenbaum's Centre for Systems Biology, Torronto, ON, CANADA.

Centrosomes are the major microtubule-organizing centers in animal cells that play an important role in spindle bipolarity, cell polarity and organelle positioning during cell division. These organelles lack any membrane and consist of an orthogonally arranged pair of centrioles surrounded by pericentriolar material (PCM). In *Caenorhabditis elegans*, the main scaffold protein is SPindle-Defective protein 5 (SPD-5, a homolog of the human CDK5RAP2), while its interacting partner SPindle-Defective protein 2 (SPD-2/ Cep192 in humans) and the Polo-Like-Kinase-1 (PLK-1, a homolog of the human PLK1) facilitate the formation of the scaffold. During interphase SPD-5 forms a thin layer around centrioles, whereas the SPD-5 containing scaffold expands in a PLK-1 dependent manner upon mitotic entry. This expansion is necessary for robust microtubule nucleation by the centrosome and the formation of a bipolar spindle. Here we present our current results on the previously unidentified centrosomal protein PeriCentriolar matrix deficient 1 (PCMD-1). We show that PCMD-1 localizes to centrosomes and is essential for cell division in *C. elegans.* We could show that the protein is required for the recruitment of pericentriolar core proteins SPD-5, SPD-2 and PLK-1 to the non-mitotic centrosome. In the absence of PCMD-1 the PCM cannot be stably formed and the integrity is disrupted. Thus, we speculate that PCMD-1 is an in *vivo* regulator of the PCM and acts as a platform for PCM proteins. We have shown that cellular levels of SPD-5 and SPD-2 remain unchanged in the absence of PCMD-1 and the proteins are not degraded on the cellular level, but not recruited to the centrosome. This finding supports the hypothesis that PCMD-1 might recruit these proteins through direct interactions. However, how exactly PCMD-1 interacts with other centrosomal proteins and how PCMD-1 itself is regulated is unknown. To identify interactions, we are currently performing different protein-protein interaction assays.

P179/B185

Plk1 Activity at Cenexin-positive Mitotic Centrosomes Is Required to Maintain Pericentriolar Material Architecture.

J. O'Connell[1], E. Curtis[1], E. Colicino[1], M. Bates[1], K. Stevens[2], L. Rathbun[1], J. Manikas[1], J. Freshour[1], **H. Hehnly**[1]; [1]Syracuse University, Syracuse, NY, [2]Clarkson University, Potsdam, NY.

The mitotic kinase, polo-like kinase 1 (PLK1), facilitates the assembly of the two mitotic spindle poles, which are required for the formation of the microtubule-based spindle that ensures appropriate chromosome distribution into the two forming daughter cells. Spindle poles are asymmetric in composition. One spindle pole contains the oldest mitotic centriole, the mother centriole, where the majority of cenexin, the mother centriole appendage protein and PLK1 binding partner, resides. We hypothesized that PLK1 activity is greater at the cenexin-positive older spindle pole. Our studies found that PLK1 asymmetrically localizes between spindle poles both in mammaliantissue culture and in Danio rerio (zebrafish) embryos under conditions of chromosome misalignment. Strikingly, chromosomes tend to misalign toward the oldest spindle pole in a cenexin- and PLK1-dependent manner. During chromosome misalignment, PLK1 activity is increased specifically at the oldest spindle pole, and this increase in activity is lost in cenexin-depleted cells. In the absence of cenexin, chromosome

misalignment increases towards both poles and correlates with fragmentation of the pericentriolar material (PCM) during metaphase. PCM fragmentation only occurs during metaphase and occurs asymmetrically, with more fragmentation occurring on the oldest spindle pole. These studies suggest that specific cenexin-mediated signaling events are required to maintain PCM architecture during metaphase. We propose a model where PLK1 activity elevates in response to misaligned chromosomes at the oldest spindle pole during metaphase where it can possibly adjust the function and organization of the PCM to assist in chromosome realignment.

P180/B186

Conserved Features and Functions of Centriolar Satellites.

C. Pachinger, A. Dammermann; Max Perutz Labs, University of Vienna, Vienna, AUSTRIA.

Centriolar satellites are cytoplasmic particles that cluster in the vicinity of centrosomes, the main microtubule organizing centers in animal cells. Despite extensive work linking satellites to various aspects of centrosome and cilium biology, their precise functional contribution continues to remain unclear. With mutations in satellite components linked to human developmental and adult disorders including microcephaly and ciliopathies, a better understanding of satellites is also of significant biomedical interest. Using reciprocal BLAST analysis we identified putative orthologs of the main satellite structural component PCM1 in both *Drosophila and C. elegans*, suggesting the distribution of PCM1 and potentially satellites may be wider than previously thought. The *Drosophila* homolog (CG10732, also known as Combover, Cmb) was originally described to be involved in planar cell polarity, with overexpression leading to disorganized wing hairs, a result we could confirm in our own hands. However, neither RNAi nor a putative loss of function mutant recapitulated this phenotype. Instead, loss of Cmb resulted in male sterility and uncoordination, potential ciliary defects. In order to further characterize Cmb we are currently examining Cmb protein localization, interactors and loss of function phenotypes at the light and electron microscopy level. In parallel, we are studying the function of the putative PCM1 ortholog in *C. elegans* by RNAi and CRISPR-mediated gene knock-out.By capitalizing on the power of the two invertebrate model organisms *Drosophila and C. elegans* we hope to be able to better define centriolar satellite function, dynamics and composition, essential to understanding their role in centrosome and cilium biology and consequently human health and disease.

P181/B187

Centriole Motility and Subcellular Positioning Require Pericentrin-like-protein and Kinesin-1.

M. R. Hannaford, Z. T. Swider, B. J. Galletta, C. J. Fagerstrom, N. M. Rusan; National Heart, Lung and Blood Institute, Bethesda, MD.

Centrosomes are the major microtubule organizing center (MTOC) of the cell. They comprise a pair of centrioles surrounded by a matrix of proteins term the pericentriolar material. Through microtubule nucleation they organize the mitotic spindle, cilia and flagella. To fulfill these functions, centrosomes must be motile to achieve proper positioning within the cell. Very little is understood about the different mechanisms of centrosome motility. Typically, it is thought to be governed by the activity of microtubule motors, pushing or pulling on the microtubules anchored at the centrosome. In some cell types, centrioles lack PCM and microtubules, and are otherwise known as inactive centrioles. Inactive centrioles must be motile as their intracellular positioning is critical for asymmetric cell division and sensory cilia formation. Despite this the mechanism by which inactive centrioles are able to move

around the cell is poorly described and not understood. Here we investigate how inactive centrioles move in interphase cells. Using high resolution live cell imaging coupled with genetic analysis in *Drosophila*, we show that centrioles move on microtubules, in a manner involved Dynein and Kinesin-1. Importantly, structured illumination microscope revealed Kinesin-1 localizes to centrioles in *Drosophila* S2 cells. To identify centriole components required for movement we performed a targeting RNAi screen and found that the centriole protein Pericentrin like protein (Plp) is necessary for centriole movement in interphase cells. Through yeast-2-hybrid analysis coupled with an in *vivo* interaction assay we mapped novel and direct protein-protein interactions between Plp and Kinesin-1. Structural analysis demonstrated that these interactions involve the conserved PACT domain. Our data support a model where Plp acts as a direct adaptor that links the centriole to motor proteins, thereby facilitating their movement. In this work we propose the first detailed mechanism of how centrioles can move independently of their role as an MTOC, in the context of developing tissue. Further understanding of inactive centriole motility has far-reaching implications in studies of asymmetric cell division and sensory ciliogenesis.

P182/B188

Analysis of the Salt-insoluble Scaffold within the Pericentriolar Material.

C. Rumpf-Kienzl, **A. Dammermann**; Max Perutz Labs, University of Vienna, Vienna, AUSTRIA.

Centrosomes are formed by the recruitment of microtubule-organizing pericentriolar material (PCM) to a pair of centrioles whose duplication once per cell cycle ensures the formation of a bipolar spindle during cell division. While the molecular pathways underlying centriole duplication are increasingly well understood, the nature of the pericentriolar material and how it is recruited to centrioles remains an area of active investigation.Classical experiments in a variety of experimental models revealed the existence of a filamentous matrix within the PCM that serves as a scaffold for the recruitment of other proteins that nucleate and anchor microtubules. The molecular composition of this scaffold, thought to be central to centrosome assembly, has not been determined. Functional experiments in *Drosophila and C. elegans* have put forward the coiled coil proteins Cnn and SPD-5, as candidates for scaffold components in their respective species. However, their presence in scaffold preparation has not been confirmed. Here, we isolate centrosomes from early-stage *Drosophila and C. elegans* embryos. As previously described, treatment with the chaotropic agents 2M KI and 6M GU strips away much of the PCM as well as centrioles, leaving behind a salt-insoluble scaffold incapable of nucleating microtubules. At least in *Drosophila*, incubation with cytoplasmic extracts results in the recovery of PCM components and restoration of microtubule nucleation potential. Using mass-spectrometry and quantitative immunofluorescence we have identified proteins enriched in scaffold preparations relative to intact centrosomes, amongst them Cnn and SPD-5, but also additional components in each system. The identification of matrix scaffolds in a wide variety of species implies a universal mechanism for centrosome assembly conserved across metazoans. We believe the molecular characterization of these scaffolds will be of particular interest given ongoing in *vitro* reconstitution experiments in both *Drosophila and C. elegans*.

P183/B189

The Formation of *Bona Fide* Centriole Wall Is a Prerogative for the Centriole-to-centrosome Conversion.

E. Atorino[1], S. Hata[1], C. Funaya[2], A. Neuner[1], E. Schiebel[1]; [1]Zentrum für Molekulare Biologie der Universität Heidelberg, Heidelberg, GERMANY, [2]Electron Microscopy Core Facility, Heidelberg, GERMANY.

The centrosome is the main microtubule-organizing centre (MTOC) of higher eukaryotic cells. It impacts on cell architecture, dynamics and cell-cycle progression, thus on tissue organisation and organism development. The first stage of centrosome inheritance is the duplication of its centriole core before the pericentriolar material (PCM) assembles around the new centriole in a maturation step termed centriole-to-centrosome conversion (CCC). It was proposed that CEP295-dependent recruitment of PCM proteins from the outside of the centriole is the first step of CCC. We show, based on the analysis of proteins that promote centriole biogenesis and centriole structure analysis via electron microscopy, that the developing centriole structure drives CCC. Depletion of the inner centriole protein CEP44 that interacts with POC1B and binds to the inner A-microtubules affects centriole structural organisation and CCC downstream of CEP295. Impairment of POC1B, TUBE1 or TUBD1, that compromised centriole integrity, also prevents CCC. Thus, formation of *bona fide* centriole via the CEP295, CEP44, POC1B, TUBE1 and TUBD1 centriole biogenesis cascade is a principle determinant for CCC.

P184/B190

Differential Requirements for Centrioles in Mitotic Centrosome Growth and Maintenance.

T. Laos[1], G. Cabral[1], J. Garbrecht[1], J. Dumont[2], A. Dammermann[3]; [1]University of Vienna, Vienna, AUSTRIA, [2]Institut Jacques Monod, Paris, FRANCE, [3]Max Perutz Labs, University of Vienna, Vienna, AUSTRIA.

Centrosomes, the predominant sites of microtubule nucleation and anchorage, coordinate spindle assembly and cell division in animal cells. At the onset of mitosis, centrioles accumulate microtubule-organizing pericentriolar material (PCM) in a process termed centrosome maturation. To what extent centrosome maturation depends on the continued activity of mitotic regulators or the presence of centrioles has hitherto been unclear. Using the *C. elegans* early embryo, we show that PCM expansion requires the Polo-like kinase PLK-1 and CEP192 (SPD-2 in *C. elegans*), but not its upstream regulator Aurora a (AIR-1), while maintenance of the PCM polymer depends exclusively on PLK-1. SPD-2 and PLK-1 are highly concentrated at centrioles. Unexpectedly, laser microsurgery reveals that while centrioles are required for PCM recruitment and centrosome structural integrity they are dispensable for PCM maintenance. We propose a model whereby centrioles promote centrosome maturation by recruiting PLK-1, but subsequent maintenance occurs via PLK-1 acting directly within the PCM.

P185/B191

Pericentrin Reduction from Basal Bodies Is Required for Sperm Development.

R. Varadarajan, K. Plevock, C. Fagerstrom, N. Rusan; National Institutes of Health, Bethesda, MD.

Centrosomes are an intriguing sub-cellular structure that nucleates and organizes microtubules (MT) and establishes basal bodies to build axonemes, cilia and flagella. Centrosomes are assembled from a pair of centrioles surrounded by pericentriolar material (PCM). Centrioles and PCM are linked through

bridge proteins that include Pericentrin, Asterless, Spd2 and Sas4, which promote PCM accumulation in co-ordination with Polo kinase during mitotic onset. As cells exit mitosis, centrosomes undergo a process known as 'Centrosome Dematuration' (CD) where the amount of PCM drops to much lower interphase levels. Our study here focuses on a much less-known process referred to as 'Centrosome Reduction' (CR), which is similar to CD but specifically occurs following meiosis and during sperm development. We first carefully documented the entire process of CR in post meiocytes and discovered that their centrioles (basal bodies) undergo a sequential removal of PCM and bridge proteins during spermatid development. We noticed that Pericentrin is reduced soon after PCM (Centrosomin and Gamma-Tubulin) is removed from the centrioles of early spermatids. Given this observation or sequential reduction and the known role of Pericentrin in male fertility, we focused our study on the mechanism of Pericentrin reduction. We began by performing structure-function analysis of Pericentrin in post-meiotic male germline cells and in dividing wing disc cells. Based on numerous Pericentrin protein truncations, we found that N terminal deletions prevented Pericentrin reduction from the centrioles, which in turn perturbed proper spermatid development and male fertility. Further biochemical characterization revealed that Pericentrin N terminus region consisting of a strong protein degradation signals. We performed genetic and proteomic screens to identify the mechanism of Pericentrin degradation, which revealed specific targets that are linked to N-end rule degradation pathway. Furthermore, we found that eliminating the N terminal degradation signals also perturbed CD in cycling wing disc cells. This ectopic interphase PCM assembly is capable of nucleating MTs, independent of Polo kinase activity. Collectively, our results therefore suggest that regulation of Pericentrin degradation is part of the underlying molecular mechanism that promotes Pericentrin reduction in developing basal bodies and restricts interphase PCM recruitment in dividing cells.

P186/B192

Phase Separation and Innate Self-assembling Capacity of Pericentriolar Scaffold Proteins Drive the Formation of a Cylindrical Architecture at Human Centrosome.

J. Ahn, L. Zhang, L. Meng, T. Kim, J. Park, K. Lee; NCI/NIH, Bethesda, MD.

The centrosome is a membraneless organelle composed of two microtubule-derived structures called centrioles and an amorphous mass of pericentriolar material (PCM). Super-resolution microscopic analyses revealed that diverse PCM proteins are concentrically localized around a centriole in a highly organized manner. We previously reported that two pericentriolar scaffold proteins, Cep63 and Cep152, interact with each other to self-assemble into a higher-order cylindrical architecture around a centriole. However, mechanisms underlying how Cep63 and Cep152 reach their threshold concentrations in the vast cytosolic space of a cell to induce the self-assembled architecture remains a mystery. Here we observed that ectopically expressed Cep63 and Cep152 cooperatively generate amorphous cytosolic aggregates that exhibit dynamic turnover of its photobleached components with those in the surroundings within a few minutes. Intriguingly, these Cep63-Cep152 aggregates efficiently underwent fusion in vivo, suggesting that they possess physicochemical properties found in liquid-like assemblies. Studies with purified recombinant proteins showed that the Cep63-Cep152 complex is capable of generating either a cylindrical structure or a hollow sphere depending on the presence or absence of spatial cues. Unexpectedly, the complex also efficiently formed condensate-like solid spheres upon providing 5% polyethylene glycol as a molecular crowder, suggesting that it has a versatile capacity in adopting morphologically distinct higher-order structures. While their internal rearrangement abilities appeared to be somewhat limited, these in vitro assemblies also underwent dynamic turnover, implying

that the phase-separating activity of Cep63-Cep152 condensates is likely critical for generating a higher-order architecture. In line with this view, pericentriolar localization of endogenous Cep63 and Cep152 was sensitive to 1,6-hexanediol, a weak hydrophobic interaction-disrupting agent proposed to distinguish between liquid-like and solid-like assemblies. Combined, these findings suggest that self-assembly of the Cep63-Cep152 complex is driven by the intrinsic property of the complex undergoing density transition and subsequent molecular interactions, and that these stepwise processes are likely important to properly self-assemble into a higher-order cylindrical architecture.

P187/B193

Macromolecular Crowding Stabilizes the *C. Elegans* Centrosome Scaffold.

M. U. Rios, 2018, A. M. Bond, W. E. Stachera, V. M. Tran, J. B. Woodruff; UT Southwestern Medical Center, Dallas, TX.

Centrosomes are membrane-less organelles that are important for mitotic cell division. By nucleating tubulin and providing anchoring sites, they act as biochemical hubs that resist microtubule pulling forces during chromosomal segregation. To achieve this, the centrosome must assemble an amorphous mass of protein called pericentriolar material (PCM). The extent to which macromolecular crowding plays a role in the morphology and stabilization of the PCM is poorly understood. Here, we used laser microsurgery to extrude centrosomes from C. elegans embryos and compared different buffer conditions for their ability to stabilize the PCM extracellularly. The PCM dissolves in all buffers but retains its full mass in conditions containing macromolecular crowders such as polyethylene glycol (PEG) or polyvinylpyrrolidone (PVP). Our results suggest that macromolecular crowding is necessary for PCM stability and its intracellular regulation may be critical to achieve proper centrosomal form and function for cell division.

P188/B194

Autophagy Is Required for Centrosome Loss-mediated Cell Cycle Arrest.

W. Wang[1], C. Kao[1], C. Huang[1], W. Jane[2]; [1]Institute of Biochemistry and Molecular Biology, Taipei, TAIWAN, [2]Institute of Plant and Microbial Biology, Academia Sinica,, Taipei, TAIWAN.

The centrosome is composed of two centrioles surrounded with the pericentriolar material (PCM). It serves as the microtubule-organizing center (MTOC) and as the template for cilia formation. It is known that centrosome loss leads to p53 activation and G1 arrest in non-transformed cells. However, the regulation that are involved in sensing and mediating centrosome loss-induced cell cycle arrest remians largely unclear. Here, we perform a SILAC-based proteomics analysis to examine the cell responses to centrosome loss and find that centrosome loss causes lysosomal accumuation in RPE1 cells. We also demonsdtrate that the accumation of lysosome in acentrosomal cells comes from the increase of autophagic flux, which is independ to p53 activity. ATG5 knockout cells are then generated to analzye the importance of autophagy in the control of cell responses to centrosome loss. Lack of autophagy promotes cell death when cells loss the centrosomes. Together, we uncover that autophagy is required for the centrosome loss-mediated cell cycle arrest in cycling cells.

P189/B195

***Drosophila Plp* Messenger RNA Localization and Translational Control.**

J. Fang, D. A. Lerit; Emory University School of Medicine, Atlanta, GA.

The centrosome is an essential organelle that regulates cell division and ciliogenesis. Centrosomes comprise a proteinaceous matrix of pericentriolar material (PCM) that surrounds a pair of centrioles. *Drosophila* Pericentrin (Pcnt)-like protein (PLP) is a key component of the centrosome that functions as a scaffold for PCM assembly required for microtubule nucleation and centrosome function. The disruption of *plp* in *Drosophila* impairs PCM recruitment and organization, while the deregulation of Pcnt in humans is associated with MOPD II and Trisomy 21. We recently found *plp* mRNA localizes to the PCM of *Drosophila* centrosomes where it colocalizes with PLP protein. While RNA is known to associate with centrosomes in diverse cell types, whether the localized centrosomal mRNA undergoes on-site translation and the physiological significance of the mRNA localization to centrosomes remains completely unknown. mRNA localization and translational control is a conserved mechanism that regulates many cellular processes, including cell migration, cell-cycle progression, and the development of embryos and neurons. Control of mRNA localization and translation is mediated by RNA-binding proteins (RBPs). Importantly, we find that *plp* mRNA interacts with the RNA-binding protein Orb, and PLP protein expression is regulated by Orb. We aim to uncover whether local *plp* mRNA contributes to centrosome function during *Drosophila* embryo development.

P190/B196

***Centrocortin* Forms a Unique Centrosome-associated Granule in *Drosophila* Embryos That Regulates Cell Division.**

P. V. Ryder, D. A. Lerit; Emory University, Atlanta, GA.

Centrosomes are the primary microtubule nucleating center of animal cells and play critical roles in cellular organization. Well known as the builder of the mitotic spindle in dividing cells, centrosomes also direct cell migration, template cilia, and organize trafficking in interphase cells. Centrosomes are composed of a pair of microtubule-based centrioles, which are surrounded by a protein matrix termed the pericentriolar material (PCM). The PCM is responsible for nucleating microtubules, and changes to PCM structure and composition during the cell cycle regulate centrosome activity. While the protein components of the centrosome are well understood, data from multiple species have implicated localized RNA as an enigmatic centrosome component. We therefore hypothesized that centrosome-associated RNA dynamically regulates centrosomes and cell division. Using quantitative imaging and single molecule fluorescence in *situ* hybridization, we found that multiple mRNAs are significantly enriched at centrosomes in *Drosophila* early embryos. One centrosome-associated transcript, *centrocortin* (*cen*), forms a micron-scale granule adjacent to centrosomes in a process regulated by the cell cycle and during development. This granule is labeled by Cen protein, *cen* RNA, and the canonical stress granule marker Fmr1. We find that Fmr1 regulates the steady state levels of *cen* RNA and protein, leading to increased granule size in the absence of Fmr1, although the granule is not required for Cen translation. The centrosome scaffold protein Centrosomin is required for formation of this granule, indicating that centrosomes actively contribute to the formation of the *cen* granule. Mutations to *cen and Fmr1* cause similar cell division phenotypes, leading us to conclude that regulation of the *cen* granule is critical for error-free cell division. We will present our latest work investigating the regulation of this novel centrosome-associated RNA granule and its role in cell division.

P191/B197

Scaffold Assembly of Pericentriolar Material in *Caenorhabditis Elegans*.

M. Nakajo, H. Kano, N. Haruta, A. Sugimoto; Graduate School of Life Sciences, Tohoku University, Sendai, JAPAN.

The centrosome is a major microtubule organizing center in animal cells. Centrosomes are composed of two centrioles and pericentriolar material (PCM). During mitosis, PCM dramatically expands and increases its microtubule nucleating activity in the process called centrosome maturation. In this process, the assembly and disassembly of PCM scaffold proteins are tightly linked to the cell cycle and spindle formation. *Caenorhabditis elegans* SPD-5 is a functional homolog of human CDK5RAP2 and *Drosophila* Centrosomin, which are the major PCM scaffold proteins controlled by phosphorylation by Polo-like kinases 1. To investigate the mechanism by which SPD-5 forms PCM scaffolds, we performed domain analysis of SPD-5 in *vivo*. We constructed worm strains expressing GFP-tagged various truncated versions of SPD-5 proteins by the CRSPR-Cas9 system. Live-imaging microscopy indicated that the C-terminal region of SPD-5 is sufficient to be recruited to PCM in the presence of the endogenous SPD-5, and to localizes at the centrioles in the absence of endogenous SPD-5. Yeast two hybrid assays indicate that the C-terminal region of SPD-5 interacts with the middle region of SPD-5. Interestingly, the C-terminal region of SPD-5 also interacts with a centriolar protein PCMD-1. These data indicate that SPD-5 proteins are recruited to centrioles through the interaction between the C-terminal region of SPD-5 and PCMD-1, and then expanded to the PCM scaffold by interacting with PLK-1 and other centrosome proteins. We also identified several centrosomal proteins that interact with PCMD-1. We will discuss the mechanism of PCM scaffold formation by SPD-5, and how it contributes to the centriole-centrosome conversion.

P192/B198

PCM1 Loss Disrupts Centriolar Satellites and Causes Genome Instability.

R. A. Denu, A. R. Lynch, S. K. Majety, M. E. Burkard; University of Wisconsin-Madison, Madison, WI.

Centriolar satellites are granular, fibrous structures that surround the centrosome and regulate movement of proteins to and from the centrosome. Their role in human cancer has not been reported. We analyzed genomic and transcriptomic alterations in the 44 genes known to localize to the centriolar satellites. Notably, genomic deletion of pericentriolar material 1 (PCM1) is the most common centriolar satellite gene alteration and occurs in up to 15% of human cancers depending on the disease site, with the most common sites being bladder, colorectal, endometrial, and prostate. PCM1 is the major defining protein of centriolar satellites, so the impact of PCM1 deletions in cancer was further pursued. We used CRISPR genome editing to knockout PCM1 in HeLa and RPE1 cells. In these knockout cells, centriolar satellites are disrupted, as evidence by dispersion of other centriolar satellite proteins such as CEP131 and CEP72. Interestingly, we find that PCM1 knockout increases the incidence of multipolar spindles in metaphase and lagging chromosomes in anaphase. We probed multiple potential mechanisms known to cause multipolarity, finding that loss of PCM1 results in disruption of centrosome integrity at the onset of metaphase. We conclude that PCM1 is important for centrosome cohesion when force is exerted on the centrosomes during mitosis. To assess whether this role of PCM1 in genomic stability is shared by other centriolar satellite proteins, we engineered CEP131 knockout cells. Concordantly, CEP131 knockout cells exhibit more multipolar spindles in metaphase. Taken together, these findings

demonstrate that PCM1-deleted cancers are more chromosomally unstable suggesting that PCM1 deletion drives carcinogenesis by increasing the incidence of multipolar spindles. Further, these results point to a broader role for centriolar satellites in maintaining genomic stability.

Sperm Head-tail Linkage Requires Restriction of Pericentriolar Material to the Proximal Centriole End.

B. J. Galletta[1], J. M. Ortega[1], S. L. Smith[1], C. J. Fagerstrom[1], J. M. Fear[2], S. Mahadevaruju[2], B. Oliver[2], N. M. Rusan[1]; [1]National Heart, Lung, and Blood Institute, NIH, BETHESDA, MD, [2]NIDDK, NIH, BETHESDA, MD.

An essential requirement for flagellated sperm is the tight attachment of the head, containing the genetic material, to the tail, needed for swimming. A failure in this attachment leads to decapitated and decaudated spermatozoa (DDS), which results in sub-fertility. The centriole is key to this attachment, building the cilium from its distal end and embedding its proximal end in the nucleus. Surprisingly, the role of the centriole itself in establishing a connection to the nucleus had not been studied. Using the *Drosophila* spermatid as a model system, we discovered a centriole centered mechanism to ensure the proper attachment of the proximal end of the centriole to the nucleus. Soon after meiosis concludes, the proximal end of the centriole is moved into close apposition with the nucleus. Based on our live cell imaging and other published data, we propose a model where the microtubule (MT) motor dynein, localized on the surface of the nucleus, pulls on MTs emanating from the centriole to bring the centriole and nucleus together. During this process the pericentriolar material (PCM), which nucleates and anchors MTs, is enriched at the proximal end of the centriole. This PCM organizes MT from the proximal end to ensure that this end is captured by MT motors on the nucleus. Furthermore we found that the major regulator of PCM, PLP, is also localized to the proximal end. We show that PLP is essential for the localization of PCM and in turn the ability of the centriole to dock to the nucleus. Using single cell RNAseq to dissect in *silico* developing spermatocytes, we found that PLP is proximally restricted by limiting the availability of its mRNA to the earliest stages of centriole growth. Altering the timing of the availability of PLP protein to later stages of centriole construction resulted in mislocalization of PLP along the entire length of the centriole. Distal PLP was sufficient to recruit PCM and organize MTs along the entire length of the centriole. Thus, the position of PLP along the centriole is sufficient to instruct the position of PCM and MTs. Finally, using light and electron microscopy we show that when PCM is mislocalized to distal regions of the centriole, the side of the centriole, instead of the proximal end, is brought into contact with the nucleus. In many of these cases, establishment of a permanent centriole/nuclear attachment fails, resulting in a separation of the sperm head and tail or DDS.

P194/B200

Domain Characterization of Pericentrin Uncovers the Role of Its Intrinsically Disordered Regions in Mediating Phase Separation and Microtubule Nucleation in Human Cells.

X. Jiang, K. Mahe, D. Ho, J. Mia, S. Yamada, L. Jao; University of California, Davis, Davis, CA.

The centrosome is a membraneless organelle that serves as the main microtubule-organizing center (MTOC) in metazoan cells. It orchestrates critical cellular processes such as cell signaling and cell division. The centrosome consists of a pair of centrioles surrounded by a proteinaceous network of pericentriolar material (PCM). It is the PCM that nucleates microtubules (MTs) and thus dictates the MTOC activity of the centrosome. The PCM is a dynamic ensemble of proteins, many of which contain

extensive intrinsically disordered regions (IDRs) that do not fold into stable secondary or tertiary structures. How the PCM encompasses the centrioles to form a membraneless, micron-sized centrosome is not well understood, in part because the roles of the IDRs in many of the PCM proteins are poorly defined. IDRs are widespread in eukaryotic proteomes and are associated with a diverse array of functions, including the formation of membraneless organelles through phase separation. Here we use an inducible gene expression system in mammalian cells to dissect the roles of IDRs in pericentrin (PCNT), a conserved PCM component critical for PCM assembly and mitotic spindle organization in vertebrates. In silico predictions suggested that PCNT and its orthologous proteins have extensive IDRs at the N-terminus and a structured centrosome targeting PACT domain at the C-terminus. Through live cell imaging analyses, we found that multiple N-terminal, IDR-containing domains of human PCNT condense into liquid-like assembly in a concentration-dependent manner in cultured cells. In particular, a region containing the putative dynein-interacting domain forms spherical “condensates” that grow in size, coalesce, and move toward the centrosome in a MT-dependent manner. Fluorescence recovery after photobleaching analyses showed that the phase of PCNT condensates transitions from liquid- to gel-like states over time. We further found that PCNT condensates selectively recruit endogenous PCM components and are capable of nucleating MTs in cultured cells. We propose that anchoring PCNT molecules around the centriole through the C-terminal PACT domains drives their N-terminal IDRs to undergo crowding-induced phase separation at the centrosome; the resulting condensates selectively recruit additional PCM components to promote the assembly of PCM and the maintenance of centrosome integrity. We further speculate that the IDR, a prevalent sequence feature found in centrosomal proteins, plays critical roles in centrosome assembly, likely in part through mediating phase transition of PCM components.

Ppp1r35 Binds and Protects Rttn within the Cell.

P. Scott, A. Holland, 21205; Johns Hopkins School of Medicine, Baltimore, MD.

The centrosome is the microtubule organizing center of the cell that guides the formation of the bipolar spindle, which functions to partition DNA to each daughter cell during mitosis. Each centrosome is comprised of two perpendicularly arranged microtubule-based structures called centrioles. Centriole copy number is tightly controlled to ensure that only a bipolar spindle forms in mitosis. Too many or too few centrioles can promote mitotic errors that drive the formation of aneuploid cells, which is a hallmark of cancer. At the start of the cell cycle each cell inherits a pair of centrioles that duplicate once prior to the next division. While centriole duplication occurs in S-phase, the newly formed centriole is duplication incompetent until it passes through mitosis. This cell cycle control of centriole duplication is known as the centriole-to-centrosome conversion (Wang *et al.* 2011 *JCB)*. We recently performed a CRISPR screen that identified PPP1R35 as a positive regulator of centriole biogenesis. A recent study has shown that PPP1R35 is required to the centriole-to-centrosome conversion (but the function of the protein has not been fully characterized) (Fong *et al.* 2018. *MBoC*). Here, I show that PPP1R35 stabilizes and protects the centriolar protein RTTN, from being proteolytically cleaved. The goal of this work is to determine the biological significance of this cleavage event and establish whether this cleavage is required for the centriole-to centrosome conversion.

Prolonged Mitosis Results in Structurally Aberrant and Over-elongated Centrioles.

D. Kong, N. Sahabandu, C. Sullenberger, A. Vasquez Limeta, J. Loncarek; Laboratory of Protein Dynamics and Signaling, NIH/NCI/CCR, Frederick, MD.

Centrioles are nine-fold symmetrical microtubule-based structures that organize centrosomes in interphase and mitosis, and assemble cilia and flagella. Centriole's length is constant for a certain cell type, although it may be different among different organisms and among different cell types of the same organism. Centrioles of human cycling cells are ~400 nm long. Centriole aberrations, which can be numerical and structural, are common in pathologies like tumors. Overly long centrioles can nucleate more microtubules, perturb mitosis and tissue architecture. How cells regulate centriole size and what leads to centriole over-elongation in tumors is not understood. An alysis of centriole structure is difficult because it requires demanding electron microscopy. Here we employ expansion microscopy to study the origins of centriole structural aberrations in large populations of human cells. We discover that centrioles do not have elongation monitoring mechanism, which renders them prone to over-elongation especially during prolonged mitosis induced by various factors, importantly including supernumerary centrioles. We further identify that mitotic centriole over-elongation is dependent on mitotic Polo-like kinase 1 (Plk1), which we uncover as a novel regulator of centriole elongation in human cycling cells. While the insufficient level of Plk1 leads to the formation of short centrioles lacking a full set of microtubule triplets, its overactivity results in over-elongated and structurally aberrant centrioles. Our data helps explain the origin of structurally aberrant centrioles and why centriole numerical and structural defects coexist in tumors.

P197/B203

Expansion Microscopy for the analysis of Centrioles and Cilia.

D. Kong[1], N. Sahabandu[1], V. Magidson[2], R. Nanjundappa[3], K. Lukasik[1], C. Sullenberger[1], M. Mahjoub[3], J. Loncarek[1]; [1]Laboratory of Protein Dynamics and Signaling, NIH/NCI/CCR, Frederick, MD, [2]Optical Microscopy and an alysis Laboratory, Cancer Research Technology Program, Frederick National Laboratory for Cancer Research, Frederick, MD, [3]Department of Medicine (Nephrology Division), Washington University, St Louis, MO.

Human centrioles are sub-resolutional microtubule (MT)-based cylindrical structures that build centrosomes and cilia. Due to their small size (~230 x 400 nm), the analysis of centriole's ultrastructural characteristics requires super-resolution imaging methods and electron microscopy, which are laborious and unsuitable for the collection of large data sets to permit a rigorous statistical analysis. Additionally, centrosomal proteins tend to form aggregates which can easily be mistaken for bona-fide centrioles. This poses a major problem in the centrosome field, as the conclusions obtained by conventional microscopy are often left uncorroborated by ultrastructural analysis. Here we present an adaptation of magnified analysis of the proteome expansion microscopy method, to be used for a robust analysis of centriole number, duplication status, length, structural abnormalities and ciliation by conventional optical microscopes. The method allows the analysis of centrioles' structural features from large populations of adherent and nonadherent cells and multiciliated cultures. We validate the method using EM and super-resolution microscopy and show that it can be used as an affordable and reliable alternative to electron microscopy in the analysis of centrioles and cilia in various cell cultures.

Combining Experimental and Modeling Approaches to Study the Effects of a Transient Centrosome Amplification Event on Steady State Levels of Supernumerary Centrosomes in the Cell Population.

N. Baudoin, D. Cimini, J. Chen; Department of Biological Sciences and Fralin Life Sciences Institute, Virginia Tech, Blacksburg, VA.

Extra centrosomes promote chromosomal instability and promote invasion in *vitro*. Moreover, centrosome amplification is common in cancer and can drive tumorigenesis in mouse models. Genome doubling, leading to tetraploid cells, is also closely linked with cancer and has been shown to promote tumorigenesis. Importantly, most cells that become tetraploid concurrently acquire extra centrosomes - for example, cytokinesis failure generates a tetraploid daughter cell with twice the normal number of centrosomes. It has been proposed that, because of the prevalence of both phenomena in cancer, tetraploidization is a major route of centrosome amplification during tumorigenesis in *vivo*. Yet, recent studies have reported that tetraploid cells grown in *vitro* generally do not exhibit increased centrosome numbers compared to diploids. We have recently identified a mechanism (Baudoin et al., 2019, BioRxiV) that leads to loss of extra centrosomes in newly formed tetraploid cells. Specifically, we found that populations of newly formed tetraploid cells rapidly lose their extra centrosomes by a process of natural selection in which tetraploid cells that inherit a single centrosome during a bipolar division with asymmetric centrosome clustering (3:1) are favored for long-term survival. We have constructed a mathematical model that describes this process in a population dynamics framework. A basic model, assuming a negative selective pressure for cells with extra centrosomes due to their likelihood to undergo multipolar division, captures centrosome loss, but under-estimates the final (steady-state) fraction of cells containing extra centrosomes within reasonable parameter ranges. Particularly, this result is constrained by the experimentally observed rates of cytokinesis failure in our model system. We found that the presence of a population of cells that cluster their extra centrosomes into bipolar spindles with high efficiency ("super-clustering," or 'SC', cells) relieves this constraint and allows our model to match experimental results. We will present experimental evidence supporting the presence of SC cells, and discuss the implications of our model for understanding to role of tetraploidy in promoting centrosome amplification in tumors.

P199/B205

***Drosophila* Cep104 Is a Novel Component of the Centriole Distal Tip Complex.**

J. M. Ryniawec[1], M. E. Zibrat[1], M. Hannaford[2], N. M. Rusan[2], G. C. Rogers[1]; [1]University of Arizona, Tucson, AZ, [2]National Heart, Lung, and Blood Institute, Bethesda, MD.

Centrioles, the core components of the centrosome, are barrel-shaped organelles composed of microtubule bundles arranged in nine-fold, radial symmetry. Although the general structure is evolutionarily conserved, centriole architecture is incredibly diverse across species and even within different cells of an individual organism. Currently, we have a limited understanding of how centrioles are built as well as the need for such variety in centriole structure. Therefore, we aim to understand the molecular mechanisms that control centriole assembly. Centriole biogenesis begins when a procentriole nucleates orthogonally off of the proximal end of an existing mother centriole. After recruitment of microtubules to the procentriole, processive centriole growth then occurs from the daughter's distal end. Understanding how cells control centriole length is important because abnormally long centrioles spawn multiple daughters simultaneously or fragment into small functional units, resulting in

centrosome amplification and, consequently, chromosomal instability. The distal tip of the centriole is occupied by a conserved set of length-regulating proteins (Cep97, CP110, and Klp10A in *Drosophila*), which we have termed the Distal Tip Complex (DTC). This ill-defined complex regulates the growth of centriolar microtubules and, thus, centriole length. At present, we lack a mechanistic understanding of this complex, the identity of all its components, and how it is regulated. By BLASTing candidate proteins against the *Drosophila* proteome, we have identified Cep104 as a novel member of the DTC. Cep104 encodes a multi-domain protein including an N-terminal Jellyroll domain, a coiled-coil region, a zinc-finger array, and a single TOG domain - a conserved tubulin binding and polymerization module. Notably, fly Cep104 lacks a C-terminal EB1-binding motif, which is present in the human homolog, and does not tip track on microtubule plus-ends. Through a series of function/structure experiments, we have identified regions of Cep104 necessary for its oligomerization and distal tip localization. Using yeast 2-hybrid and co-immunoprecipitation, we have mapped the binding domains within Cep104, CP110, Cep97, and Klp10A, revealing a more complete interaction network of the DTC. Our findings suggest that Cep104 is a key member of the DTC and, thus, participates in the control of centriole growth.

P200/B206

Role of Cep128 in Formation of the Centriolar Subdistal Appendage.

H. Kashihara[1], S. Chiba[1,2], S. Kanno[3], K. Suzuki[1,4], T. Yano[1], S. Tsukita[1]; [1]Osaka University, Suita, JAPAN, [2]Osaka City University, Osaka, JAPAN, [3]Tohoku University, Sendai, JAPAN, [4]Juntendo University, Tokyo, JAPAN.

The mother centriole in a cell has two appendages, the distal appendage (DA) and subdistal appendage (SDA), which have roles in generating cilia and organizing the cellular microtubular network, respectively. In the knockout (KO) cells of Odf2, the component of the DA and SDA, both appendages simultaneously disappear. Here, using super-resolution structured illumination microscopy (SR-SIM), we found that the signal for GFP-tagged Odf2 overlapped considerably with that of immunofluorescently labeled Cep128. We further found that Cep128 knockdown (KD) caused the dissociation of other SDA components from the centriole, including centriolin, Ndel1, ninein, and Cep170, while Odf2 was still associated with the centriole. In contrast, the DA components remained associated with the centriole in Cep128 KD cells. Consistent with this observation, we identified Cep128 as an Odf2-interacting protein by immunoprecipitation. Taken with the finding that Cep128 deletion decreased the stability of centriolar microtubules, our results indicate that Cep128 associates with Odf2 in the hierarchical assembly of SDA components to elicit the microtubule-organizing function.

Oocyte Meiotic Spindles & Polar Body Extrusion: a Role for CLS-2/CLASP in Contractile Ring Assembly.

A. Schlientz, B. Bowerman; University of Oregon, Eugene, OR.

During oocyte meiotic cell division, discarded chromosomes are extruded into small polar bodies. However, the cues that mediate polar body extrusion are not well understood. To gain insight, we are investigating the relationship between oocyte meiotic spindle assembly and polar body extrusion. We have begun by exploring the role of CLS-2, a *C. elegans* CLASP family member, and are comparing its

spindle assembly and polar body extrusion defects to those in *mei-1/Katanin* and *klp-18*/kinesin 12 mutants. Previous studies of CLASP family proteins indicate that they function to promote microtubule stability and may be important for regulating interactions between the microtubule and actin cytoskeletons, but how they contribute to polar body extrusion remains unknown. We used CRISPR/Cas9 to generate putative *cls-2* null alleles, and live imaging with fluorescent protein fusions to assess CLS-2/CLASP requirements. As others have reported, *cls-2(-)* mutants have chromosome segregation defects during oocyte meiosis. In addition, we have found that microtubule levels are reduced, and the mutant oocytes fail to assemble bipolar spindles. Intriguingly, ~85% of *cls-2(-)* oocytes fail to extrude a polar body during meiosis I (n=91) and exhibit increased levels of global cortical furrowing compared to wild type. Moreover, based on live imaging of NMY-2/non-muscle myosin and ANI-1/anillin, the polar body contractile ring structure appears fragmented and discontinuous in *cls-2(-)* mutants. Similar to *cls-2(-)* oocytes, *mei-1 and klp-18* mutant oocytes fail to segregate chromosomes, and *mei-1/Katanin* mutants also frequently fail to extrude a polar body during meiosis I (83%, n=23), although global cortical furrowing appears normal. In contrast, oocytes depleted of *klp-18/kinesin 12* usually do extrude polar bodies (15% failure in meiosis I, n = 20) and also have more normal global cortical furrowing. Unlike the fragmented and disorganized contractile ring structures observed in *cls-2(-)* mutants, oocytes lacking *mei-1/Katanin* and *klp-18/kinesin 12* form more normal contractile rings, though later scission appears to fail frequently in *mei-1* depleted oocytes. We conclude that CLS-2/CLASP has a unique and important role in contractile ring assembly during oocyte meiosis. We are currently analyzing spindle associated furrow dynamics, cortical non-muscle myosin dynamics, and spindle components to further compare spindle assembly and polar body extrusion defects in these and other mutants. We anticipate that such a comparative analysis will provide insight into the cues that mediate polar body extrusion during oocyte meiotic cell division.

P202/B208

The Ran Pathway Uniquely Regulates Cytokinesis Depending on Cell Fate in *Caenorhabditis elegans* Embryos.

I. Ozugergin, K. Mastronardi, A. Piekny; Concordia University, Montreal, QC, CANADA.

Cytokinesis is a highly conserved process that divides a cell into two daughters. This process must be tightly regulated to avoid aneuploidy or cell fate changes. Cytokinesis requires the assembly and ingression of a RhoA-dependent actomyosin ring that constricts to pinch in the overlying cortex. This process is regulated by microtubule-dependent and -independent mechanisms, and our lab found that a chromatin-sensing mechanism also regulates cytokinesis. In interphase cells, proteins with nuclear localization signals (NLS) are bound by importin-α/-β for import into the nucleus where they are released by Ran-GTP. RCC1/RanGEF is associated with chromatin in the nucleus, while RanGAP is in the cytosol forming a gradient of Ran-GTP that is retained during mitosis. An inverse gradient of importins free to bind to cargo forms with higher levels near the cortex, and we found that human anillin, a scaffold for the contractile ring, is regulated by importin-binding for its function in cytokinesis. Importin-β binds directly to a conserved NLS in the C-terminus of anillin to facilitate its cortical recruitment. While different mechanisms function redundantly to regulate cytokinesis in symmetrically dividing cells in *vitro*, their requirement in *vivo* likely varies depending on cell geometry, fate or ploidy. We studied the role of the Ran pathway in cytokinesis of cells of two different fates in the early *C. elegans* embryo. The first division gives rise to a larger anterior AB cell fated to give rise to multiple tissues, and a smaller posterior P_1 cell fated to become germline. Imaging AB and P_1 cell division from anaphase onset with

high temporal resolution revealed that each cell has unique ingression kinetics, supported by differences in the cortical accumulation of ANI-1 in the two cells. Lowering Ran-GTP levels via partial RNAi of RCC1 (RanGEF) increased kinetics of the early phases of cytokinesis, which was suppressed by co-depletion of contractility regulators such as ECT-2 (RhoAGEF) or LET-502 (Rho Kinase). Interestingly, co-depletion of ANI-1 suppressed RCC1 phenotypes in AB, but not P_1 cells, suggesting that the two cells have different pathway requirements. This was supported by differences in cytokinesis phenotypes caused by depletion of importin-α (IMA-3), -β (IMB-1) or both. We are currently testing this hypothesis using CRISPR to generate mutations in ANI-1 that disrupt IMB-1 binding. Thus, our findings reveal differences in mechanisms regulating cytokinesis in cells with different fates, and emphasize the need to study cytokinesis in cells in *vivo*.

P203/B209

Probing the Role of ESCRT-III Proteins in Cytokinetic Abscission and the Abscission Checkpoint.

D. R. Mackay[1], D. M. Wenzel[2], J. J. Skalicky[2], E. Paine[2], W. I. Sundquist[2], K. S. Ullman[1]; [1]Dept. Of Oncological Sciences, University of Utah, Salt Lake City, UT, [2]Dept. Of Biochemistry, University of Utah, Salt Lake City, UT.

Cytokinetic abscission, the final stage of cell division, involves tight coordination and regulation of microtubule and membrane remodeling events along with finely-tuned dynamics in protein localization. A checkpoint just prior to this physical separation of daughter cells termed the abscission (or NoCut) checkpoint is thought to ensure that residual mitotic errors, such as malformed nuclear pores, chromatin bridges, or under-replicated DNA lesions, have been corrected before proceeding to the irreversible step of abscission. Thus, the abscission checkpoint helps maintain DNA integrity and ensures that nascent daughter nuclei are fully formed and poised for proper function. While it is well-established that Aurora B kinase is a master regulator of abscission timing and the checkpoint itself, questions still remain about the spatiotemporal regulation of protein recruitment and activities required to orchestrate midbody stabilization and its consequent resolution. Recent studies have found that certain subunits of the ESCRT membrane remodeling machinery play key roles in both abscission and the abscission checkpoint. To understand better how ESCRT proteins contribute to this step of cell division, we explored three specific ESCRT-III binding partners: SPASTIN, KATANIN p60, and CALPAIN7. In each case, we have characterized features that specify their MIT domain interactions with particular ESCRT-III proteins and tested their roles in abscission and abscission regulation. These studies reveal that distinct ESCRT-III factors target the microtubule severing proteins SPASTIN and KATANIN p60 to the midbody for distinct functions in abscission. Moreover, we unexpectedly found that SPASTIN is also required for the abscission checkpoint. We further discovered a previously uncharacterized role for the cysteine protease CALPAIN7 in the abscission checkpoint. The catalytic activities of both SPASTIN and CALPAIN7 are essential to their role in the abscission checkpoint, highlighting the variety of biochemical activities that contribute to abscission regulation.

P204/B210

Mammalian Cell Growth Dynamics in Mitosis.

T. P. Miettinen, J. Ho Kang, L. F. Yang, S. R. Manalis; Massachusetts Inst Technology, Cambridge, MA.

The extent and dynamics of animal cell biomass accumulation during mitosis are unknown, primarily because growth has not been quantified with sufficient precision and temporal resolution. To study

growth in mitosis, we use suspended microchannel resonator, a non-invasive mass sensor that allows us to quantify single-cell cell mass accumulation rates with 0.05 % precision and a temporal resolution of 1 min, while simultaneously monitoring fluorescent and biophysical markers of mitotic stages. We also support the findings of mass accumulation measurements with single-cell protein synthesis assays. We find that in various animal cell types, growth rates in prophase are commensurate with or higher than interphase growth rates. Mass accumulation is only stopped as cells approach metaphase-to-anaphase transition and mass accumulation resumes in late cytokinesis. Mitotic arrests stop growth independently of arresting mechanism. For mouse lymphoblast cells, growth in prophase is promoted by CDK1 through increased phosphorylation of 4E-BP1 and cap-dependent protein synthesis. Inhibition of CDK1-driven mitotic translation reduces daughter cell growth. Overall, our high-resolution approach to cell growth monitoring counters the traditional dogma that growth during mitosis is negligible and provide insight into antimitotic cancer chemotherapies.

P205/B211

Cytokinetic Bridge Supports Tensions Required for Rosette Formation*In Vivo*.

J. M. O'Connell, J. Manikas, H. Hehnly; Syracuse University, Syracuse, NY.

Multicellular rosettes are cellular intermediates observed during the formation of diverse organ systems. Rosettes are polarized, transient epithelial structures that can be prerequisite to the development of an adult organ. A representative example of this process is the formation of Kupffer's Vesicle (KV) during development of *Danio rerio*(zebrafish),where non-polarized cells self-organize into a polarized rosette and then a sphere encircling a fluid-filled lumen. Once fully formed, KV establishes zebrafish left-right asymmetry and is a conserved process amongst vertebrate systems. Where most rosettes identified thus far employ either apical constriction or planar polarized constriction for their formation, we have identified a unique example of rosette assembly that incorporates the last stage of cell division, cytokinesis. Our studies address the question that is fundamental to understanding KV formation: What physical properties and biomechanical steps are required for cells to assemble into a rosette and subsequently into a functional KV with a central lumen? to test this idea, we compared recoil velocity and relaxation time of cell interfaces during KV morphogenesis as KV cells transition from non-polarized, to a polarized rosette, to epithelial cells surrounding a fluid filled lumen. We calculated an average recoil velocity of 0.0022 µm/msec for non-polarized pre-rosette KV cells, 0.0075 µm/msec at cell-cell interfaces within a rosette, and then 0.0091 µm/msec post lumen formation, these studies suggest that cell-cell interfaces are supporting increasing amounts of tension as KV lumen forms. We next correlated recoil velocities following laser ablation that were obtained in *in vitro*cell culture of cytokinetic cells at proximal locations to the cytokinetic midbody, a proteinaceous structure located at the center of the cytokinetic bridge. We compared these recoil velocities to KV rosette cell-cell interfaces in proximity to the center of the rosette where cytokinetic bridges are located. With these studies, membrane recoil velocities were greatest closest to the cytokinetic bridge and decreased significantly as targeted ablation was moved away from the cytokinetic bridge. This study suggests that there might be a range in tensions supported along the cytokinetic bridge that is highest next to the cytokinetic midbody and lowest at the furthest point away from the midbody. This creates a testable model in which cytokinetic bridges may be functionally required for packing cells in an energetically unfavorable yet biologically useful confirmation.

P206/B212

Pp2a Inhibitory Protein Sds23 Contributes to Cell Division Symmetry.

K. L. Schutt, J. B. Moseley; Dartmouth College, Hanover, NH.

Animal and fungal cells divide through the assembly, anchoring, and constriction of a contractile actomyosin ring (CAR) during cytokinesis. Timing and position of the CAR must be tightly coordinated with events in mitosis, such as spindle assembly and elongation, to prevent defects during the division of the cell. A major regulator of mitotic timing is the conserved heterotrimeric Protein Phosphatase 2A (PP2A), which counteracts the activity of the conserved Cyclin-dependent kinase (CDK), the primary driver of cell cycle progression. Although the role of PP2A in mitotic timing has been well-characterized, the role for PP2A in cytokinesis has been less clear. Loss of PP2A in yeast causes defects in cytokinesis, placing PP2A in pathways that regulate the CAR. Here, we report that Sds23, an inhibitor of PP2A family protein phosphatases, promotes the symmetric division of fission yeast cells through spatial control of cytokinesis and spindle assembly. Fission yeast cells undergo symmetric divisions through medial assembly of the CAR, which results in two equally sized daughter cells following constriction. We found that *sds23Δ* cells divide asymmetrically due to misplaced CAR assembly, followed by sliding of the CAR away from its assembly site. A microscopy-based screen revealed that these mutant cells exhibit delayed recruitment of putative CAR anchoring proteins, including the glucan synthase Bgs1. These results identify the PP2A regulatory network as a critical component in the signaling pathways coordinating cytokinesis. In addition to this role in cytokinesis, we find that Sds23 promotes proper spindle assembly and elongation, as *sds23Δ* cells exhibit asymmetric spindles and decreased rates of spindle elongation. During anaphase in *sds23Δ* cells, the spindle initially elongates asymmetrically toward one end of the dividing cell. This spindle defect is corrected later in anaphase before the CAR constricts. Spindle asymmetry in *sds23Δ* cells results from a novel mechanism that is distinct from previously identified mechanisms including microtubule protrusions. Our results show how Sds23, an inhibitor of PP2A-family protein phosphatases, promotes both bipolar spindle elongation and cytokinesis positioning during fission yeast cell division. These two steps ensure the overall symmetry and success of the cell division process.

P207/B213

The Cell Polarity Kinase Pak1 Controls Cytokinesis and Cell Separation.

J. Magliozzi, J. Moseley; Dartmouth College, Hanover, NH.

For polarized growth of cells, protein kinases regulate the assembly of cytoskeletal structures at the correct time and place. Large cytoskeletal structures must also be assembled in a regulated manner during cytokinesis and cell separation. We performed a visual screen to identify cell polarity protein kinases that might also function in cytokinesis and cell separation. We found that the Cdc42-activated protein kinase Pak1 (also called Orb2 and Shk1) colocalizes with the assembling cytokinetic ring and remains in the cell middle during septation. Mutations in *pak1* led to defects in cytokinetic ring assembly and cell separation, as well as previously known cell polarity defects. We performed a phosphoproteomic screen and identified novel Pak1 targets that were verified as direct substrates in vitro. Top targets included proteins that function in polarized growth, cytokinesis, and septation. For cytokinesis, we found that Pak1 regulates the localization of its substrates Mid1 and Cdc15 to the cell cortex and the cytokinetic ring. For cell separation, Pak1 phosphorylates the RNA-binding protein Sts5 to prevent its assembly into P-body granules. The cell separation defect of *pak1* mutants was suppressed

by loss of *sts5*. These results show that Pak1 acts directly on components of the cytokinetic ring, but unexpectedly promotes the later stages of cell division by inhibiting the assembly of ribonucleoprotein granules. More broadly, our work reveals that cell polarity signaling proteins coordinate diverse events to promote cell division at the end of the cell cycle.

Microenvironmental Stiffness Promotes Multinucleation Upon Induction of Epithelial-mesenchymal Transition.

E. M. Rabie[1,2]; [1]Princeton University, Princeton, NJ, [2]Rutgers Robert Wood Johnson Medical School, Piscataway, NJ.

Cytokinetic abscission, the final stage of cell division during which the parent cell physically separates to yield two identical daughter cells, is a complex process. Despite being highly regulated, cytokinesis can fail, generating multinucleated cells. Multinucleation is a sign of genomic instability, an enabling characteristic of cancer. We recently found that the induction of epithelial-mesenchymal transition (EMT), which increases the invasiveness of cells, causes multinucleation in mammary epithelial cells on stiff microenvironments that have mechanical properties similar to those found in breast tumors, but not on soft microenvironments reminiscent of the normal mammary gland. We found that on stiff microenvironments, EMT signaling through Snail upregulates the expression of the midbody-associated filament-forming GTPase, septin-6, and disrupts cytokinetic abscission, thus causing multinucleation. Cells cultured on soft microenvironments do not upregulate septin-6, fail to undergo EMT, and complete cytokinesis normally. Using a septin-6-promoter luciferase-reporter construct, we found that inducing EMT by treating cells with TGFβ or expressing Snail ectopically increases activation of the septin-6 promoter on stiff microenvironments. These data suggest that transcriptional responses to EMT inducers depend on mechanical properties of the microenvironment.

Linear F-actin Promotes Clustering of Rhoa at the Equatorial Plasma Membrane during Cytokinesis.

J. Sacher, **E. Zanin**; Biocenter - LMU Munich, Munich, GERMANY.

During cytokinesis the mother cell is physically divided into two daughter cells. Failure in cytokinesis results in tetraploid cells with supernumerary centrosomes that can cause developmental defects. Constriction of the mother cell is mediated by a contractile ring that assembles underneath the plasma membrane during anaphase. Formation of the contractile ring is triggered by the activation of the small GTPase RhoA, which in turn induces linear F-actin polymerization and myosin II activation. RhoA is prenylated at its C-terminus and is therefore thought to rapidly diffuse within the plasma membrane. How rapidly diffusing active RhoA is maintained within a narrow equatorial zone is less clear due to the difficulty in generating functional fluorescently labeled RhoA probes. To overcome this difficulty we established a RNAi-resistant GFP-tagged RhoA transgene in the nematode *C. elegans* that can replace endogenous RhoA during cytokinesis. We started to investigate GFP::RhoA dynamics in the absence of endogenous RhoA by live-cell imaging one-cell embryos. GFP::RhoA localizes to a narrow equatorial zone and clusters in a dense network during contractile ring assembly. We found that RhoA clusters specifically contain active RhoA and that partial depletion of the RhoA GTPase activating proteins RGA-3/4 broadens the RhoA zone. Therefore, our findings suggest that the formation of a narrow RhoA zone requires rapid flux through the GTPase cycle, a model proposed by Bement and colleagues previously

(Bement et al., 2006). RhoA has two putative membrane targeting motifs: a poly-basic sequence (PBS) and CAAX motif. Our data suggest that the PBS and the CAAX motif are both required for RhoA membrane binding and function however that they are not sufficient to target RhoA to equatorial clusters. To identify factors targeting RhoA to equatorial clusters we tested whether contractile ring components such as linear F-actin has any role. Depletion of the formin CYK-1 did not prevent the accumulation of RhoA but abolished the formation of a dense RhoA network at the cell equator during anaphase. Furthermore in *cyk-1(RNAi)* embryos GFP::RhoA accumulation was delayed and the RhoA zone was broader. In summary, we find that RhoA clusters in a dense network at the equatorial membrane during anaphase. The formation of a narrow RhoA zone depends on formin-nucleated F-actin and rapid GTPase flux through the GTPase cycle. Furthermore formin-induced F-actin promotes the formation of a dense RhoA network at the furrow site. We propose that the formation of a dense RhoA network facilitates contractile ring assembly and successful cytokinesis.

P210/B216

Exclusion of NuMA from the Equatorial Cortex Promotes Timely Cytokinesis.

S. Sana, A. Rajeevan, S. Kotak; Indian Institute of Science - Bangalore, Bangalore, INDIA.

NuMA is an essential mitotic protein which guides spindle elongation during anaphase because of its cortical localization and its ability to interact with cortical dynein. In anaphase cortical NuMA localization is dependent on its interaction with phosphoinositides- PtIns(4)P and PtIns(4,5)P2. Interestingly, despite the uniform presence of PtIns(4)P and PtIns(4,5)P2 at the cell cortex, NuMA is excluded from the equatorial cortex during anaphase. We have shown earlier that NuMA is excluded from the equatorial cortical region in a CYK4 dependent manner. However, the mechanisms by which CYK4 excludes NuMA remained elusive. By conducting a candidate-based RNAi screen, we uncovered that beside CYK4, loss of RhoGEF ECT2 that acts downstream of CYK4 also leads to accumulation of NuMA at the equatorial cortex. In the absence of ECT2, NuMA, dynein and dynactin occupy equatorial cortical surface. Therefore, we wondered if the presence of dynein at the equatorial cortical region perturbs robust spindle elongation by counteracting forces from the polar cortical region. Surprisingly, loss of ECT2 marginally impact chromosomes segregation and thus spindle elongation in anaphase. Next, we sought to investigate the mechanism by which ECT2 excludes NuMA from the equatorial cortical region. ECT2 interacts with the similar phosphoinositides to which NuMA binds. To test in vivo if the competition between ECT2 and NuMA for the similar phosphoinositides is responsible for NuMA exclusion, we generated stable cell lines expressing full-length ECT2 and the one lacking lipid-binding potential. Notably, loss of lipid-binding ability of ECT2 cannot prevent NuMA localization at the equatorial cortical region in contrast to the cells expressing full-length ECT2. This data strongly supports the notion that NuMA and ECT2 compete for similar lipids. In a converse experiment, we have artificially targeted NuMA and analyzed its impact on cortical ECT2 and its downstream effector Rho. Importantly, targetting NuMA at the equatorial cortical surface strongly impact Rho levels and significantly delays the furrow initiation. Altogether, our work suggests that cortical NuMA localization in anaphase is spatiotemporally maintained by the RHO-GEF ECT2 and this is vital for regulating proper timing of cytokinetic furrow onset.

Astral Microtubules Regulate Rho Activity and Actomyosin Ring Constriction in Fission Yeast.

S. E. R. Dundon, T. D. Pollard; Yale University, New Haven, CT.

Animal, fungal, and amoeboid cells use microtubules in a mitotic spindle to segregate DNA and an actomyosin contractile ring to form a cleavage furrow during cytokinesis. These different cytoskeletal components must be coordinated to produce viable daughter cells. Work in metazoans has implicated Rho signaling in this integration, though mechanistic details remain incompletely understood. While active Rho is known to localize to the division site in yeast models, evidence for microtubule involvement in its regulation has been lacking. By carefully examining a 20-year-old temperature-sensitive *Schizosaccharomyces pombe* (fission yeast) strain, we discovered evidence for Rho signaling mediating crosstalk between mitotic microtubules and cytokinesis in this organism. *The S. pombe cps1-191* strain was reported to arrest with non-constricting rings at 36°C. Our detailed examination has revealed two insights: 1) rings do not arrest but constrict 30-fold slower than in wild-type cells; and 2) the D277N substitution in β-glucan synthase 1 (Bgs1) that causes temperature sensitivity in the *cps1-191* strain is insufficient for the constriction phenotype. Rings in *bgs1-D277N* cells constrict slower than rings in wild-type cells but faster than rings in *cps1-191* cells. Using whole-genome sequencing, we discovered >250 mutations in *cps1-191*. We further investigated one of these mutations, the S338N substitution in Mto2, a γ-tubulin regulator. Rings constrict as slowly in *bgs1-D277N* cells bearing the *mto2-S338N* mutation or *mto1Δ* (Mto2's binding partner) as in the *cps1-191* strain. However, *mto2-S338N* or *mto1Δ* cells expressing *bgs1*$^{+}$ divide normally, suggesting the Mto1/2 complex plays a redundant role in ring constriction. Others have reported that *mto1Δ* cells lack astral microtubules, which we confirm, and we found that *mto2-S338N* cells also nucleate fewer astral microtubules than wild-type cells. Based on work in other systems, we hypothesized that astral microtubules could influence Rho signaling, which subsequently regulates actomyosin activity. Compared with wild-type cells both *mto2-S338N* and *mto1Δ* cells recruited more Rho1-GTP to the equator, where it persisted longer during cytokinesis. Therefore, we propose that the γ-tubulin complex and astral microtubules have roles in coordinating Rho activity and actomyosin ring constriction in *S. pombe*.

The Integrated Mitotic Stem Cell, a Holistic View of Human Cell Division.

C. Hookway, S. M. Rafelski,.Allen Institute for Cell Science; Allen Institute for Cell Science, Seattle, WA.

The Allen Institute for Cell Science is developing a state space of structural signatures of the undifferentiated human induced pluripotent stem cell (hiPSC) to understand the principles by which cells reorganize as they traverse the cell cycle and differentiate. To do this, we take advantage of the fluorescently tagged hiPSC lines that make up the Allen Cell Collection (allencell.org), each expressing an endogenously tagged protein representing a particular organelle or structure. We also develop image-based assays and segmentation algorithms for quantitative analyses, taking advantage of high replicate, high resolution 3D images, which are available online. We have categorized cells in this image collection as mitotic or non-mitotic and sorted the mitotic cells into four categories: prophase, early prometaphase, prometaphase/metaphase, and anaphase/telophase/cytokinesis. From these categorized cells, we created an integrated mitotic stem cell model (imsc.allencell.org) by aligning and overlaying one representative cell for each of five stages (four mitotic plus interphase) of mitosis for 15 structures. We found that all structures could be assigned to three classes of behavior:

redistribution/reorganization, recompartmentalization, and structural maintenance. The integrated model also highlighted relationships between some of the structures, which we further confirmed using "label-free" based structure integration and dual-edited cell line (containing both mEGFP- and mTagRFP-T-tagged structures) approaches. We investigated the variation in structure localization patterns throughout mitosis and found that both cell shape and structure localization patterns were less varied (most stereotyped) during metaphase than in any other stage of the cell cycle. We also found that all reorganizing structures began their transformations in early prometaphase. To identify the order of events during this period of cytoplasmic reorganization, we are sub-dividing the prophase to metaphase transition to create a pseudo-time axis along which to analyze the behavior of reorganizing structures in an integrated fashion. We are also systematically quantifying the variations in organelle inheritance as the cells transition from mitosis into early G1. These observations highlight the usefulness of high-replicate data in understanding structural relationships and changes during cell state transitions.

P213/B219

Stability of the Fission Yeast Contractile Ring Requires Rapid Myo2 and Myp2 Turnover and Lateral an choring of Myo2.

R. Alonso Matilla[1], S. Thiyagarajan[2], B. O'Shaughnessy[3]; [1]Columbia University, New York, NY, [2]Sathish Thiyagarajan, New York, NY, [3]Ben O'Shaughnessy, New York, NY.

Actomyosin contractile machines in the cell are intrinsically vulnerable to contractile instabilities: one location that has a little excess contractile material tends to draw in more contractile material, enhancing its contractility so more material is drawn in, and so on, in a runaway process. Here we studied how such instabilities are kept under control in the cytokinetic contractile ring. We mathematically modeled the fission yeast contractile ring incorporating the two myosin-II isoforms found in the ring, Myo2 and Myp2.We find that a stable, homogeneous ring requires that: (i) turnover of Myo2 and Myp2 be faster than a critical value, and (ii) motion of Myo2 and Myp2 in the ring is sufficiently restrained by lateral anchoring to the membrane or crowding effects in the ring, so that the mobilities are below a critical value. If these conditions are not met, the contractile ring is catastrophically affected by a hierarchical density aggregation and tension loss. The contractile ring model is a highly coarse-grained continuum description that incorporates the two myosin-II isoforms: membrane-anchored Myo2 in protein complexes called nodes, and clusters of Myp2 assumed unanchored.The model articulates mechanisms with a clarity not available from more detailed simulation approaches. We find that a runaway buildup of the contractile components, Myo2 and Myp2, is prevented by sufficiently rapid turnover and sufficiently low mobilities. The role of turnover was previously revealed by experiments using cell ghosts of the fission yeast S. japonicus, where turnover is almost completely abolished (Chew et al., 2017). To further explore the effect of turnover on ring stability we developed a complementary approach to this coarse-grained continuum model, a 3D molecularly explicit simulation of rings in cell ghosts with turnover absent. The experiments showed myosin-II puncta moving bidirectionally around the ring and merging into larger puncta. Simulation results showed similar hierarchical aggregation of myosin-II clusters, consistent with these experiments and with our continuum model. These results support the hypothesis that a major role of turnover in the contractile ring is to prevent aggregation instabilities.

Mechanical Feedback Regulates Contractile Ring Constriction and Cell Wall Growth in Fission Yeast and Is Destabilized by Mutations.

S. Thiyagarajan, Z. McDargh, S. Wang, B. O'Shaughnessy; Columbia University, New York, NY.

The actomyosin contractile ring constricts and divides the cell during cytokinesis, but is far from isolated. Ring constriction is tightly coupled to membrane addition, cortical and cytoplasmic flow and, in cell-wall enclosed organisms such as fission yeast, septation, the growth of new cell wall. Ring constriction and these coupled processes are highly interdependent, but the mechanisms are poorly understood. In fission yeast, this interdependence is well documented. Mutations of myosin-II in the ring produce irregularly shaped septa and inhomogeneous distributions of beta glucan synthases (Bgs) that grow cell wall (Zhou et al., 2015), while mutations in cell-wall-synthesizing proteins generate misshapen septa and rings, and ring-septum separation (Munoz et al., 2013). These findings are unexplained. Here we developed a molecularly explicit quantitative model that fully integrates the fission yeast contractile ring dynamics and cell wall growth kinetics for the first time. We find the observed irregularities originate in a mechanical feedback system that is destabilized by mutations. In wild type cells mechanical communication between the contractile ring and septum growth systems regulates constriction-septation, but mutations generate positive mechanical feedback that destabilizes both interdependent systems. The 3D ring model incorporates extensive data on component amounts and organization for fission yeast, coupled to a 3D description of stochastic Bgs-mediated septum growth behind the constricting ring, with Bgs mechanosensitivity as quantified (Thiyagarajan et al, 2015). Simulations revealed a symbiotic relation between the ring and septation systems. Ring organization depended profoundly on septum shape because ring tension pulled components to the septum tip, while irregular septum edges drastically impaired ring organization by provoking snapping away of straight bridges. Septum growth depended on the ring, as ring tension set the ring's location and the local septum growth rate. In wild type simulations of the model, the interdependence produced well-organized rings and almost circular septum holes. Ring tension suppressed septum roughness by promoting (suppressing) growth in septum valleys (peaks) while circular septa mechanically regulated ring organization. With mutated components, simulations produced defective organization matching experimental phenotypes. Simulations with mutant *myo2-E1* reproduced the observed straight bridges, non-uniform myosin-II distribution, misshapen septa and irregular septum growth rates correlated with myosin-II distribution (Laplante et al., 2015, Zhou et al., 2015). With mutated Bgs, rings detached into bridges and septa were misshapen as seen experimentally (Munoz et al., 2013).

Laser Ablation Uncovers the Mechanical Properties of the Constricting Contractile Ring in Fission Yeast.

M. Moshtohry[1], M. W. Elting[1,2], C. Laplante[3,2]; [1]Department of Physics, North Carolina State University, Raleigh, NC, [2]Computational Developmental Biology Cluster, North Carolina State University, Raleigh, NC, [3]Department of Molecular and Biomedical Sciences, North Carolina State University, Raleigh, NC.

Cytokinesis in animals, fungi, and amoebas is a robust process that requires the constriction of a contractile ring of actin, myosin, and other conserved proteins. Recent studies have begun to unravel the molecular architecture of the contractile ring. However, we still do not understand how this organization, and its dynamics, support force generation due to the experimental challenges of probing

force in live cells. We overcome this challenge by using laser ablation to cut the contractile ring and measure the kinetics of the resulting severed ends. After cutting the contractile ring, the free ends recoiled away from each other and moved back toward each other to heal the severed ring. The profile of recoil followed an exponential relaxation with interruptions when the recoiling ends stalled for short periods of ~10 s. These data support that severing the contractile ring releases internal tension and that the profile of recoil of the severed ends is influenced by drag forces caused by anchoring of the contractile ring to the plasma membrane/cell wall. We hypothesized that defects in tension production and ring anchoring would alter the kinetics of the severed ends of the contractile ring in response to laser ablation. We cut contractile rings in control, tension-defective (*Δmyp2 myo2-E1*), and anchoring-defective (Cdc15p depleted) cells and found distinct responses in each background. In control cells, the cut free ends of the contractile ring recoiled by ~720 nm over the first 50 s after ablation, after which the recoiling stopped and the cut ring healed over time. In tension defective cells, no recoil was observed after laser ablation and the cut ring healed rapidly. In anchoring defective cells, the cut ring continuously recoiled over the entire imaging period. We tracked these severed rings for ~500 s, until the signal was completely photobleached or the severed ends of the contractile ring left the imaging plane. By the end of our imaging, the severed ends had recoiled ~ 950 nm and healing of the ring was never observed. In conclusion, laser ablation is a powerful tool that can be used to uncover the mechanical properties of the contractile ring and ascribe mechanical functions to cytokinetic proteins.

The an illin Homolog Mid1p Is Dispensable for Cytokinetic Node Assembly in Fission Yeast.

K. Bellingham-Johnstun, E. C. An ders, C. Bruinsma, J. Ravi, **C. Laplante, 27606**; North Carolina State University, Raleigh, NC.

The contractile ring is a machine built of actin, myosin, and other highly conserved proteins that constricts during cytokinesis. In fission yeast, nodes, protein complexes containing the an illin homolog Mid1p and the Myosin-II molecule Myo2, assemble in a broad band at the site of cell division and coalesce into a contractile ring. Mid1p is thought to be essential for node assembly because broad bands of nodes are not detected in *Δmid1* cells. Rather, strands made of the same cytokinetic proteins as nodes loop to form the contractile ring in these cells. Mid1p leaves the contractile ring prior to the onset of constriction giving rise to the assumption that the node structure is not maintained during constriction. How proteins organize within the constricting contractile ring remains unclear mainly because of the limited tools to probe molecular organization in live cells. We used quantitative high-speed Fluorescence PhotoActivation Localization Microscopy (hsFPALM) in live cells to probe protein organization at the nanometer scale, a ~tenfold improvement in resolution over confocal microscopy. We hypothesized that contractile rings and strands contain nodes that are packed too densely to be resolved by confocal microscopy. Using hsFPALM, we found that both the strands and contractile rings of *Δmid1* cells contain nodes. We found that rings assemble from two different types of strands in *Δmid1* cells: pre-existing and *de novo* strands. Pre-existing strands are present in cells that have previously failed at cytokinesis, can form contractile rings independently of the cell cycle stage, and require actin polymerization by the formin For3p. *De novo* strands assemble as expected during anaphase and are independent of For3p. The molecular organization of nodes in the contractile rings of *Δmid1 and* wild-type cells and in the broad bands of wild-type cells is comparable. However, the distribution of Myo2 heads is more compact in the nodes of pre-existing strands in *Δmid1* cells. This difference in the spreading of the Myo2p heads is actin-dependent. In conclusion, our work 1) shows

that Mid1p is dispensable for node formation and maintenance, 2) indicates that nodes are components of the contractile ring, and 3) suggests that node protein organization is governed by the molecular composition and organization of the underlying actin network.

An Unexpected Twist to Escrt Proteins.

A. Bertin[1], m. Al qabandi[1], N. Miguet[2], W. Weissenhorn[2], p. bassereau[1], s. Mangenot[1]; [1]Institut Curie, paris, FRANCE, [2]IBS, Grenoble, FRANCE.

The ESCRT-III is a conserved protein complex that mediates membrane remodeling and scission in the context of essential cellular processes among which multi-vesicular body formation, cell division and virus budding. The ESCRT pathway has been extensively studied in *vivo and* reconstituted in *vitro* using yeast proteins (Snf7, Vps2, Vps24). In *Homo Sapiens*, the ESCRT-III complex is composed of at least 12 proteins, called Charged Multivesicular Body Protein (CHMP 1-7). We have focused our attention on CHMP4 (human homolog of yeast Snf7), CHMP2 and CHMP3 (homologs of yeast Vps2 and Vps24 respectively). It has been proposed that filaments composed of Snf7/CMHP4, the main structural component of ESCRT-III polymer, can form spiral springs that would promote membrane deformation by buckling (Chiaruttini et al.). To address whether ESCRT proteins can remodel membranes, we have used a bottom-up approach and analyzed, using cryo-electron microscopy and cryo-tomography, how different combinations of ESCRT proteins would deform lipid vesicles, in vitro. When bound to biomimetic membranes, spirals of CHMP4 are flat and membranes are not significantly deformed. Instead, the spirals would rather have a tendency to flatten liposomes. Unexpectedly, the addition of a combination of CHMP2A and CHMP3 or CHMP2B together with CHMP4 induced a dramatic tubulation of vesicles. Most of the membrane was remodeled and tubulated. Regular “Corskrew-like” or “zigzag”-like tubular patterns were visible in 2D images or 3D reconstructions obtained from cryo-tomography. Besides two sets of filaments were visualized, one being parallel to the axis of the tubes and the other one being orthogonal. Hence, CHMP4, by itself, was unable to deform membranes, in *vitro* and required the presence of CHMP2/3 proteins. We believe that this behavior might reflect the activity of ESCRT proteins in membrane remodeling in situ. **References** CHIARUTTINI, N et al., 2015. Relaxation of Loaded ESCRT-III Spiral Springs Drives Membrane Deformation. Cell, 163(4), pp. 866-879.

P218/B224

Cytokinesis in *Silico*: Development of an Agent-based Model of Actomyosin Behavior in the Contractile Ring of an Early Embryo.

J. B. Alberts[1], C. B. Shuster[2], J. H. Henson[3]; [1]Not a Box LLC, Seattle, WA, [2]New Mexico State University, Las Cruces, NM, [3]Dickinson College, Carlisle, PA.

We have used super-resolution light microscopy and platinum replica TEM to elucidate the ultrastructural organization of the contractile ring (CR) in early sea urchin embryos. These experiments employ an isolated cortex approach that takes advantage of the large size of the embryo’s CR (10X larger than a cultured mammalian cell), the thinness of the preparation (allowing for TIRF/SIM microscopy and platinum replica TEM), and the unique perspective afforded by examining the CR on the cytoplasmic face of the plasma membrane. To date our studies suggest that the CR initiates as a broad stripe of clusters containing myosin II, actin, septin2 and anillin, which then appear to congress over time into the narrower, linear array characteristic of mature CRs. In parallel with these imaging

experiments, we are examining the behaviors of CR-related actomyosin assemblages in *silico*. Our 3D agent-based computer model incorporates detailed characteristics of actin and myosin II that include: 1) actin filament polymerization and monomer hydrolysis status, filament flexibility, severing, crosslinking, and interaction with myosin II heads; 2) myosin II motors that are approximated as three rigid physics bodies —head, neck and tail— constrained by springs that undergo ATPase-based changes in conformation to generate force via power strokes. Myosin and actin filament behaviors are benchmarked with known biophysical properties and classic in *vitro* assays. Our preliminary simulations include the generation of CR-like organization in an *S. pombe*-based context, where myosins move larger protein nodes along actin filaments. In addition, we are examining higher order emergent behaviors in simulations based on assemblages of anti-parallel actin filaments and myosin II mini-filaments; here dense actomyosin patches form that mirror the coalescence of clusters seen in our imaging of CR dynamics in sea urchin embryos. We are incorporating information derived from our imaging experiments - such as distances between clusters, approximate numbers of myosin filaments per cluster, rate of cluster congression, location of scaffolding proteins, and orientation of actin filaments - into the in *silico* model in order to determine if we can recapitulate the cluster to linear array transition. We are confident that a productive crosstalk between our imaging experiments and these computational simulations will result in a deeper understanding of CR structure and function.

P219/B225

Chromatin Sensing Regulation of Cytokinesis Is Stronger in Cancer Cells with Higher Ploidy.

M. C. Husser, K. Larocque, N. Skaik, S. Koh, B. Jaunky, V. J. J. Martin, A. Piekny; Concordia University, Montreal, QC, CANADA.

Cytokinesis occurs at the end of mitosis and leads to the physical separation of two daughter cells. This process needs to be tightly regulated to prevent aneuploidy and cell fate changes. It is mediated by the ingression of an actomyosin contractile ring that pulls the plasma membrane inwards to separate the two cells. Assembly and ingression of the ring is spatiotemporally regulated by spindle-dependent and -independent pathways. Recently, our lab found that a cue associated with chromatin also regulates cytokinesis by influencing the function of anillin, which is a component of the ring. During interphase, proteins with nuclear localization signals (NLS) are bound by importins and brought into the nucleus where Ran-GTP releases them. High levels of Ran-GTP are found in the nucleus since its GEF, RCC1, is associated with chromatin, and low levels of Ran-GTP are in the cytosol where Ran GAP is located. During mitosis, this gradient of active Ran is retained with low levels of Ran-GTP near the cortex permitting importins to remain bound to proteins. Our lab found that importins bind to the NLS of anillin to mediate its cortical recruitment and function for cytokinesis. Interestingly, prior studies found that anillin is highly over-expressed in many cancers, and other studies showed that cancer cells with aneuploidy have steeper Ran-GTP gradients. Thus, we propose that cancer cells with aneuploidy rely more heavily on chromatin-sensing and anillin function for cytokinesis. This would ensure that furrow positioning correlates with chromatin position to avoid mitotic catastrophe. To test this, we determined the requirement for anillin in aneuploid cancer cells (A549 and HeLa), compared to near-diploid cancer cells (HCT116) and normal fibroblasts (HFF-1). Following anillin knockdown, HeLa and A549 cells frequently failed cytokinesis, while HCT116 and HFF-1 were significantly less affected. However, these cells originate from different tissues, which could explain their different requirements for anillin. To further determine if ploidy contributes to changes in anillin-dependency, we altered the ploidy of HCT116 cells and determined their requirement for anillin. A higher proportion of HCT116 cells with

higher ploidy failed cytokinesis compared to their lower ploidy counterparts. To continue to test the relationship between ploidy and anillin requirement, we used CRISPR to endogenously tag anillin with mNeonGreen in HCT116 cells. With this tool we can separate cells based on ploidy, then correlate precise changes in anillin levels with cytokinesis phenotypes in cells with low (2n) vs. high (4n or 8n) ploidy. This work sheds light on how the Ran pathway may help aneuploid cells avoid mitotic catastrophe during mitosis, and could be a novel therapeutic target against cancer cells.

P220/B226

Role of the Cdc48 Segregase in the Robust Execution of an aphase.

D. Vijayakumari, W. Williams, S. Hauf; Virginia Tech, Blacksburg, VA.

Cdc48 (p97/VCP) is a AAA+ ATPase which can separate proteins from their binding partners and unfold them in the process. Cdc48 typically acts on ubiquitinated proteins, which it can bind through its cofactor complex Ufd1/Npl4. By segregating ubiquitinated substrates from their non-ubiquitinated binding partners, Cdc48 may protect the non-ubiquitinated partner from co-degradation. Securin and cyclin B are two key proteins whose degradation is critical in mitotic progression. The degradation of securin liberates its binding partner separase; separase then cleaves cohesin, resulting in sister chromatid separation. Degradation of cyclin B leads to declining Cdk1 activity and mitotic exit events. Interestingly, fission yeast *cdc48* mutants have been shown to contain low levels of separase and lose viability during mitosis. This suggests a role for Cdc48 in mitosis, possibly by acting on ubiquitinated securin. We find lower cellular levels of securin but normal levels of cyclin B in the fission yeast *cdc48* mutant. In addition to the lower securin levels, we observe slower kinetics in the drop of nuclear securin and delayed sister chromatid separation by live cell imaging. In contrast, the rate at which nuclear cyclin B drops and the events downstream of its degradation are unaffected. We also observe slower kinetics in the drop of nuclear securin in a *ufd1* mutant, supporting that Cdc48 may act on ubiquitinated securin. We are investigating the mechanisms by which Cdc48 regulates separase and securin levels, and the factors or features that dictate the specificity of Cdc48 towards the securin-separase arm of mitotic regulation. Overall, our results hint to a pivotal role of Cdc48 for anaphase, whose mechanistic basis remains to be elucidated.

P221/B227

Screening for Deubiquitinating Enzymes an tagonizing APC/C Activity in Fission Yeast.

V. Gopala Krishna, E. Baybay, S. Hauf; Virginia Tech, Blacksburg, VA.

The anaphase promoting complex (APC/C) is an E3 ubiquitin ligase which triggers anaphase by ubiquitinating securin and cyclin B, thereby targeting them for proteasomal degradation. While the mechanisms governing APC/C activity have been extensively studied, much less is known about deubiquitinating enzymes (DUBs) that may antagonize APC/C activity. To find antagonists of the APC/C, we overexpressed individual DUBs in fission yeast (*S. pombe*) and tracked the degradation kinetics of GFP-tagged cyclin B and securin by live-cell imaging. We focused on DUBs that have been reported to localize to the nucleus, where the APC/C, securin and cyclin B are enriched during mitosis. We found that overexpression of *S.p.* Ubp16 (*S.c.* Ubp10) lead to elevated securin levels, a slight reduction in the securin degradation kinetics, and appearance of the 'cut' phenotype, where cytokinesis proceeds without chromosome separation. This complements findings by others in budding yeast that overexpression of Ubp10 stabilizes APC/C substrates. Deletion of *ubp16* slightly rescued growth of an

APC/C mutant strain, supporting that Ubp16 may antagonize the APC/C. We are continuing to screen for additional candidates and investigating whether Ubp16 indeed plays a role during mitosis and if it acts directly on securin or other substrates.

Regulations of UNC-13/Munc13 Protein Ync13 Localization and Function during Fission Yeast Cytokinesis.

S. Zhang, K. Zhang, J. Wu; Ohio State University, Columbus, OH.

Ync13 is a member of the UNC-13/Munc13 protein family, whose animal homologs are essential priming factors for SNARE complex assembly during exocytosis. Our previous studies suggest that Ync13 is involved in both exocytosis and endocytosis. Ync13 is critical for the normal distribution of cell-wall enzymes and some other proteins on the division plane. β-Glucan synthase Bgs4, a transmembrane protein, accumulates at the center instead of its normal even distribution on the division plane in *ync13Δ* cells. However, it remains unknown how Ync13 localization and functions are regulated since its binding partners have not been identified. Here we found that Rho-GAP Rga7 and coiled-coil protein Rng10 are binding partners of Ync13 by affinity purification and mass spectrometry. Rga7, Rng10, and Ync13 colocalized on the plasma membrane at the cell tips during interphase and at the division site during cell division. Ync13 was almost abolished at division site in *rga7Δ* or *rng10Δ* cells. In addition, mistargeted Rga7 or Rng10 by Tom20 could recruit Ync13 to mitochondria, which suggesting that the localization of Ync13 depends on both Rga7 and Rng10. Moreover, mutants of *ync13*, *rga7*, and *rng10* had similar cell-lysis phenotype and were synthetic lethal. We hypothesize that Rga7 and Rng10 help to anchor Ync13 on the plasma membrane at the division site to regulate Bgs4 trafficking during cytokinesis. Consistently, Bgs4 level at the division site is significantly lower in *rga7Δ* and *rng10Δ* cells and moved slowly from the late Golgi compartments to the cleavage site in *rga7Δ* cells. We also found mistargeted Rga7 or Rng10 recruited Bgs4 to mitochondria, indicating that Rga7/Rng10 may directly interact or form a complex with Bgs4. The late arrival and lower levels of Bgs4 result in septal defects in cytokinesis and the lysis of separating cells.

Kinetochore Assembly and Functions 1

P223/B229

Essentiality of CENP-A Depends on Its Binding Mode to HJURP.

T. Hori[1], J. Cao[1], Y. Arimura[2], K. Nishimura[1], M. Ariyoshi[1], H. Kurumizaka[3], T. Fukagawa[1]; [1]Osaka university, Suita, JAPAN, [2]The Rockefeller University, New York, NY, [3]The university of Tokyo, Bunkyo-ku, JAPAN.

The centromere is an essential genome region where the kinetochore is established for faithful chromosome segregation. In most organisms, centromeres are specified by sequence-independent epigenetic mechanisms through deposition of histone H3-variant CENP-A into chromatin. Therefore, it is critical to know how CENP-A is deposited into centromeric chromatin. We previously showed that the chicken Mis18 complex directly binds to the CENP-A nucleosome and is recognized by the pre-deposition CENP-A-H4-HJURP (CENP-A specific chaperon) complex for new CENP-A incorporation (Hori et al., Dev. Cell, 2017). But, it is still unknown how the pre-deposition CENP-A-H4-HJURP complex correctly transfers the CENP-A into centromeric chromatin. Here, we analyzed various CENP-A domains

in the chicken DT40 cells, using a gene complementation assay. We found that while both N- and C-terminal tails of CENP-A were dispensable, the alpha-1 helix region near CATD (CENP-A targeting domain) was essential for CENP-A deposition and centromere maintenance in chicken DT40 cells, which is not the case for human CENP-A. Consistent with our CENP-A characterization, a contact residue in HJURP to the CENP-A alpha-1 helix was also essential in DT40 cells. To understand why the CENP-A alpha-1 helix is essential in chicken but not in human, we prepared a chimeric HJURP in which the CATD binding region of chicken HJURP was replaced with the corresponding region of human HJURP. Surprisingly, expression of the chimeric HJURP suppressed CENP-A incorporation defects in cells expressing the CENP-A alpha-1 helix mutant. Additional biochemical analyses revealed that binding affinity of CATD to HJURP was stronger in human than in chicken, suggesting that CATD-HJURP interaction is sufficient and is not necessary to use the CENP-A alpha-1 helix for its HJURP binding in human cells. We also identified key residues in human HJURP sufficient for CENP-A binding in the absence of the alpha-1 helix contact. Interestingly, HJURP in most species except for some of the mammals do not contain these residues and appear to use the CENP-A alpha-1 helix for HJURP binding. We propose that essentiality of CENP-A depends on its binding mode to HJURP, which is variable during evolution. This gives us a new insight into how CENP-A is co-evolved with HJURP.

P224/B230

CENP-C Unwraps the CENP-A Nucleosome through the H2A C-terminal Tail.

A. Ali-Ahmad[1], S. Bilokapic[2], I. Schafer[3], M. Halic[2], **N. Sekulic**[1]; [1]University of Oslo, Oslo, NORWAY, [2]St. Jude Children's Hospital, Memphis, TN, [3]Max Planck Institute of Biochemistry, Martinsried, GERMANY.

Centromeres are defined epigenetically by nucleosomes containing the histone H3 variant CENPA, upon which the constitutive centromere-associated network of proteins (CCAN) is built. CENPC, is considered to be a central organizer of the CCAN. We provide new molecular insights into the structure of CENP-A nucleosomes, in isolation and in complex with the CENP-C central region (CENP-C^{CR}), the main CENP-A binding module of CENP-C. We establish that the short αN-helix of CENP-A promotes DNA flexibility at the nucleosome ends, independently of the sequence it wraps. Furthermore, we show that, in *vitro*, two regions of CENP-C (CENP-C^{CR} and CENP-C^{motif}) both bind exclusively to the CENP-A nucleosome. We find CENP-C^{CR} to bind with high affinity due to an extended hydrophobic area made up of CENP-A^{V532} and CENP-A^{V533}. Importantly, we identify two key conformational changes within the CENP-A nucleosome upon CENP-C binding. First, the loose DNA wrapping of CENP-A nucleosomes is further exacerbated, through destabilization of the H2A N-terminal tail. Second, CENP-C^{CR} rigidifies the N-terminal tail of H4 in the conformation favoring $H4^{K20}$ monomethylation, essential for a functional centromere.

P225/B231

CDK1 Regulates CENP-A-CENP-C Interaction in Vertebrate Kinetochore.

M. Hara, R. Watanabe, M. Ariyoshi, T. Fukagawa; Osaka University, Suita, JAPAN.

Chromosomes duplicated in S-phase have to be accurately segregated to daughter cells in M-phase. The accurate chromosome segregation requires the kinetochore, a large protein complex, which makes a linkage between chromosome and spindle microtubules. Clarifying how the kinetochore is assembled is critical for understanding of the principles of the accurate chromosome segregation. The kinetochore is formed on the centromere of each chromosome that is epigenetically defined by CENP-A, a centromere-specific histone H3 variant. Constitutive Centromere Associated Network (CCAN), a kinetochore

subcomplex, localizes to the centromere throughout the cell cycle via binding of CENP-A nucleosome. In M-phase, CCAN recruits another kinetochore subcomplex KMN (Knl1, Mis12 and Ndc80 complexes) network, which directly binds to microtubules, connecting chromosomes to spindle microtubules. As CCAN provides the centromere-kinetochore interface, a key question to be addressed is how CCAN interacts to the centromere and how the interaction is regulated. CENP-C is one of CCAN subunits, which directly binds to the CENP-A nucleosome in vitro. We recently showed that the CENP-C C-terminus region interacts with centromere during M-phase but not during interphase in chicken DT40 cells, suggesting that the CENP-C-centromere interaction is regulated in cell cycle progression, although CENP-C constitutively localizes to centromere. Then, the question we set to clarify was how the dynamic CENP-C-centromere interaction was regulated. We found that a conserved motif, CENP-C motif, which binds to the CENP-A nucleosome, is required for the CENP-C-centromere interaction in M-phase. We also identified a key CDK1 phosphorylation site that regulates the CENP-C-centromere interaction. In fact, mutation of this site reduced centromere localization of CENP-C in M-phase. Further analyses revealed that the CDK1 phosphorylation facilitates interaction between the CENP-C motif and the CENP-A nucleosome. Finally, we demonstrated that the CDK1-depenent CENP-C-centromere interaction contributes to chromosome segregation. These results suggest that CENP-C phosphorylation by CDK1 is a key regulation for the CENP-A-CENP-C interaction in M-phase and provides a model in which dynamic interaction of the centromere-CCAN during cell cycle progression is important for functional kinetochore assembly.

P226/B232

Constitutive Presence of R Loops at Centromeric Chromatin Contributes to Chromosome Instability.

P. K. Mishra[1], K. S. Bloom[2], M. A. Basrai[1]; [1]Genetics Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD, [2]Department of Biology, University of North Carolina, Chapel Hill, NC.

Aneuploidy is a hallmark of many cancers and a significant driver of tumorigenesis. An euploidy, observed in 90% of solid tumors, is caused by chromosome instability (CIN), characterized by the unequal distribution of chromosomes into two daughter cells and/or structural rearrangements of the genome. One of the key determinants for chromosomal stability is the centromere, which serves as a site for kinetochore assembly, mediates kinetochore-microtubule attachment and spindle assembly checkpoint function. R-loops, which are the by-product of DNA-RNA hybridization, are largely undetected at the centromeric chromatin in budding yeast and reported to persist in a *HPR1* deletion strain. However, the molecular role of R loops at the centromeres and its physiological significance remain poorly understood. Here we report that constitutive presence of centromeric R loops affects kinetochore integrity and CIN in budding yeast. We show that Hpr1, associates with the centromeric chromatin, and interacts in *vivo* with the evolutionarily conserved centromeric histone H3 variant Cse4 (CENP-A in humans). Deletion of *HPR1* causes accumulation of centromeric R loops, reduction in the levels of centromere-bound Cse4 and its assembly factor Scm3 (HJURP in humans), with a concomitant increase in histone H3 at the centromeric chromatin. We found that constitutive presence of centromeric R loops interferes with kinetochore function as increased frequency of chromosome loss were observed *hpr1Δ* strains. In summary, our results have begun to uncover the mechanisms by which constitutive presence of centromeric R loops contributes to CIN and may contribute to aneuploidy in cancers.

P227/B233

The Role of Rad50 in Cenp-a Deposition at the Centromere.

K. Kitagawa; Greehey Children's Cancer Research Institute, UT Health San an tonio, San an tonio, TX.

In most eukaryotes, the centromere is a single chromosomal locus that attaches to microtubules to ensure delivery of one copy of each pair of sister chromatids to daughter cells during cell division. Centromere identity does not rely on specific DNA sequences, but, rather, is associated with large arrays of repetitive DNA. Centromere specification is thought to occur via deposition of the centromere-specific histone H3 variant, CENP-A. After DNA replication, "old" centromeric nucleosomes are distributed to the replicated chromatids. In mammals, deposition of newly synthesized CENP-A occurs at the centromere in the G1 phase of the cell cycle. This step is crucial for proper centromere inheritance and function. Yet the molecular mechanism remains unclear. We have shown that CENP-A deposition at the centromere requires ubiquitylation on lysine 124 (K124) that is catalyzed by the CUL4A-RBX1-COPS8 E3 ligase. Introduction of the K124R mutation abrogates the centromeric localization of CENP-A, while addition of a mono-ubiquitin at the C-terminus of CENP-A K124R restores its centromeric localization (*Dev Cell, 2015*). Fachinetti et al. reported that EYFP-CENP-A K124R mutant cells are viable (*Dev Cell, 2017*). However, we recently found that EYFP tagging, as used in Fachinetti et al., induces a non-physiological ubiquitylation event at a different lysine of EYFP-CENP-A-K124R, which allows EYFP-CENP-A-K124R to bind to HJURP. We also found that Flag-tagged or untagged CENP-A K124R mutants are nonfunctional in cells (*Dev Cell, in press)*. We reported that overexpression of mono-ubiquitin-fused CENP-A creates ectopic centromeres at non-centromeric regions (neocentromeres) (*Cell Reports, 2016*), suggesting that identifying ubiquitin-dependent CENP-A interactors provides crucial information regarding the mechanisms that control centromere assembly and maintenance. Our IP-mass spec has identified RAD50 as a ubiquitin-dependent CENP-A interactor. IP-Western blots confirmed that CENP-A interacts with the MRN complex (RAD50, MRE11, and NBS1). We found that RAD50 depletion delocalizes CENP-A from the centromere, suggesting that the MRN complex is required for CENP-A deposition at the centromere. The MRN complex is structurally similar to SMC complexes; both bind to CENP-A, and both are required for CENP-A deposition. This finding implies that the MRN complex may stabilize CENP-A in nucleosomes. We also found that DHX9 (RNA helicase A) binds CENP-A in a CENP-A ubiquitylation-dependent manner. DHX9 is involved in R-loop (which contains DNA-RNA hybrids and displaced ssDNA) formation or resolution. ATR is activated by R-loops at the centromere for faithful chromosome segregation. These results suggest that CENP-A is involved in ATR activation via R-loops at the centromere.

P228/B234

Cenp-a Overexpression and Mislocalization Contribute to an euploidy and Karyotypic Heterogeniety in Human Cells and Xenograft Mouse Model.

R. L. Shrestha[1], A. Rossi[1], D. Wangsa[1], E. Suva[1], C. Sanders[2], A. Hogan[3], S. Difilippantonia[2], D. Wangsa[1], D. R. Foltz[3], D. Fachinetti[4], T. Ried[1], M. A. Basrai[1]; [1]National Institutes of Health, Bethesda, MD, [2]Frederick National Laboratory for Cancer Research, Frederick, MD, [3]Northwestern University, Evanston, IL, [4]Institut Curie, Paris, FRANCE.

Aneuploidy results from chromosomal instability (CIN) and contributes to tumorigenesis and tumor heterogeneity. Therefore, it is crucial to understand the molecular pathways contributing to aneuploidy. Centromere associated proteins are the key regulators for chromosomal stability. Centromeric

localization of an evolutionarily conserved histone H3 variant, CENP-A is essential for chromosomal stability. Overexpression (OE) and mislocalization of CENP-A to non-centromeric regions contributes to CIN in yeast and flies. CENP-A OE and mislocalization have been observed in several cancers and correlates with poor prognosis. However, the correlation between CENP-A mislocalization, aneuploidy and tumorigenesis has not been investigated. We recently showed that mislocalization of CENP-A to non-centromeric regions results in CIN in HeLa and RPE1 cells. Here, we show that CENP-A mislocalization contributes to aneuploidy and enhances the tumorigenic potential of DLD1 cells with CENP-A OE in doxycycline inducible manner ($DLD1^{Dox\text{-}CENP\text{-}A\text{-}YFP}$). CENP-A mislocalization to non-centromeric regions contributes to CIN in $DLD1^{Dox\text{-}CENP\text{-}A\text{-}YFP}$ cells, as ascertained by defective chromosome segregation and increased incidence of micronuclei. Mislocalization of CENP-A weakens the kinetochores due to reduced levels of outer kinetochore protein, Nuf2, creating unstable kinetochore-microtubules attachments in $DLD1^{Dox\text{-}CENP\text{-}A\text{-}YFP}$ cells. To investigate if the mislocalization of CENP-A affects the metastatic and invasiveness of cells, we performed trans-well assays. Higher invasion, that could be rescued by suppression of CENP-A mislocalization, was observed in $DLD1^{Dox\text{-}CENP\text{-}A\text{-}YFP}$ cells, but not in control DLD1 cells, confirming that CENP-A mislocalization enhances the invasiveness of cells. To examine whether CIN phenotypes we observed in cultured cells could be translated *in-vivo*, we used a xenograft mouse model using $DLD1^{Dox\text{-}CENP\text{-}A\text{-}YFP}$ cells. Tumors in mice fed with DOX diet regressed significantly at first, followed by slow growth. Cells derived from these tumors displayed CENP-A mislocalization, higher incidence of micronuclei and severe aneuploidy with karyotypic heterogeneity. Consistent with the slow growth of tumors, prolonged treatment of $DLD1^{Dox\text{-}CENP\text{-}A\text{-}YFP}$ cells with high concentration of DOX (1.0µg/ml for 5 days) showed positive staining for apoptosis marker, an nexinV in the majority of cells. These results suggest that even though CENP-A induced aneuploidy leads to apoptosis and slow growth of tumors, the karyotypic heterogeneity may contribute to poor prognosis of cancers with CENP-A OE. In summary, our results show that CENP-A OE and mislocalization contribute to aneuploidy and karyotypic heterogeneity in cell lines and xenograft mouse model.

P229/B235

Centromere Incompatibility as the Basis for Chromosome Segregation Defects in Inviable *Xenopus*Hybrids.

M. Kitaoka, R. Heald; University of California, Berkeley, Berkeley, CA.

Centromere incompatibility as the basis of chromosome segregation defects in inviable *Xenopus* hybrids Maiko Kitaoka* and Rebecca Heald Department of Molecular and Cell Biology, University of California, Berkeley, CA 94720, USA *Presenting author: mkitaoka@berkeley.edu **ABSTRACT** Despite the evolutionarily conserved function and importance of centromeres to mediate faithful segregation of replicated chromosomes, the underlying DNA sequences and centromeric proteins are rapidly evolving, even among closely related species. Interestingly, faulty chromosome segregation has been reported in a number of inviable hybrids, contributing to post-zygotic developmental barriers and speciation. However, the molecular mechanisms underlying specific chromosome loss in hybrids is poorly understood. *Xenopus* frog species provide an ideal system to study hybridization and genome evolution, as hybrids produced when *X. laevis* or *X. borealis* eggs are fertilized by *X. tropicalis* sperm (*l*e×*t*s and *b*e×*t*s) are viable, but the reverse crosses (*t*e×*l*s and *t*e×*b*s) are not. Both inviable hybrids show chromosome segregation defects, however, whole genome sequencing revealed that *t*e×*l*s hybrids lose two specific *X. laevis* chromosomes, while *t*e×*b*s hybrids lose regions of four specific *X. borealis* chromosomes. We used *Xenopus* egg extracts to demonstrate that a subset of *X. laevis* and *X. borealis*

chromosomes lost CENP-A, the core centromeric histone variant, as well as Ndc80, the key outer kinetochore component that attaches to spindle microtubules, after one cell cycle. CENP-A loss is cell cycle-dependent, as unreplicated paternal sperm retain all CENP-A localization. *X. laevis* chromosome centromere localization is rescued with addition of *in vitro* transcribed and translated CENP-A with its chaperone HJURP to *X. tropicalis* cytoplasmic extracts, although *X. borealis* centromeres are not rescued. Preliminary results suggest that transcription affects centromere assembly in these hybrids, as triptolide inhibition of RNA Pol II can also rescue CENP-A localization. Ongoing experiments aim to rescue segregation defects in inviable hybrid embryos and uncover the mechanisms underlying specific paternal chromosome mis-segregation and inviability in *Xenopus* hybrids.

P230/B236

Centromere Strength Is Transgenerationally Inherited through the Male but Not Female Germline.

A. Das, V. Fu, B. E. Black, M. A. Lampson; University of Pennsylvania, Philadelphia, PA.

Centromeres direct genetic inheritance but are not themselves genetically inherited. Instead, centromeres are defined epigenetically by the presence of a histone H3 variant, CENP-A. According to existing models for centromere inheritance, preexisting CENP-A nucleosomes serve as templates to direct new assembly, which quantitatively maintains centromere chromatin through every cell cycle in cycling somatic cells. To test this model in vivo in the mammalian germline, we created CENP-A hemizygous mice with reduced levels of centromere chromatin in the gametes. We show that genetically wild-type progeny from two *cenpa+/-* hemizygous parents have partially reduced centromere chromatin in somatic tissue and in the male germline and that these levels are transgenerationally inherited. But we find wild-type levels of CENP-A in the female germline, indicating that CENP-A levels reset prior to prophase I arrest in the oocyte. Furthermore, when only one parent is hemizygous, we don't observe any detectable differences between maternal and paternal centromeres in adult progeny, indicating equilibration between maternal and paternal centromeres. Based on these results, we propose two key exceptions to template-dependent centromere inheritance. First, a unique assembly mechanism in the female germline increases CENP-A chromatin, possibly to protect against loss during the prolonged prophase arrest. Second, CENP-A chromatin can differ quantitatively between sperm and egg chromatin in the zygote, but CENP-A redistributes in the early embryo to equalize maternal and paternal centromeres, providing a mechanism to suppress centromere drive.

P231/B237

Enrichment of Aurora B Kinase at the Inner Kinetochore Controls Outer Kinetochore Assembly.

M. Bonner, J. Haase, **A. E. Kelly**; National Cancer Institute, Bethesda, MD.

The outer kinetochore is assembled and disassembled every cell cycle, and loss of this regulation can lead to errors in chromosome segregation. Aurora B kinase plays a pivotal role in kinetochore assembly through the phosphorylation of the Mis12 complex (Mis12C) subunit Dsn1. Current models posit that Dsn1 phosphorylation relieves autoinhibition, which allows Mis12C binding to the inner kinetochore component CENP-C. However, the mechanism by which kinetochore assembly is restricted to centromeres is unknown. Using *Xenopus* egg extracts and biochemical reconstitution, we show that multiple factors synergize to ensure the specificity of kinetochore assembly. First, we find that centromere-bound CENP-C molecules become static in mitosis and do not exchange with the soluble pool, as observed in human cells. This shift in CENP-C dynamics restricts productive formation of

Mis12C-CENP-C complexes to kinetochore-localized CENP-C. Second, we show that Mis12C autoinhibition by the N-terminal tail of Dsn1 serves as a barrier to phosphorylation by Aurora B kinase. Our data indicate that substrate access is enhanced through transient interactions of the Mis12C with kinetochore-bound CENP-C, and that the Dsn1 phosphorylation rate is enhanced by high local concentrations of Aurora B kinase proximal to CENP-C. We will discuss our latest efforts to identify the receptor for the CPC at inner kinetochores. Thus, we propose that the coincidence of CENP-C and Aurora B at inner kinetochores is required for proper kinetochore assembly only at centromeres.

P232/B238

Building a Functional Kinetochore: from Microtubule to Centromere.

G. E. Hamilton[1], L. A. Helgeson[1], E. I. Henry[1], A. Zelter[1], M. J. MacCoss[1], C. A. Asbury[1], Y. N. Dimitrova[2], T. N. Davis[1]; [1]University of Washington, Seattle, WA, [2]Genentech Inc., South San Francisco, CA.

Perhaps the largest and most intricate of all microtubule-associated protein machines, the kinetochore consists of over fifty different proteins organized into subcomplexes. Their architecture is branched, with more copies of the outer microtubule-binding subcomplexes than centromeric nucleosomes at their base. The kinetochore performs vital mechanical functions during mitosis: coupling chromosome movement to microtubule dynamics and sensing the tension that signals chromosome biorientation. Much is known about the microtubule-coupling interface of the kinetochore, and previous work has demonstrated that the Ndc80 subcomplex binds to microtubules and transmits force to the Mis12 subcomplex (Mis12c^{MIND}). However, it has been unclear how the distinct, underlying branches within the centromere-proximal inner kinetochore contribute to the kinetochore's load-bearing ability. Here, using a set of six recombinantly purified budding yeast kinetochore subcomplexes, we show that they can spontaneous self-assemble into functional, load-bearing tethers between dynamic microtubule tips and nucleosomes containing the centromere-specific histone variant. We quantify the load-bearing and microtubule tip-coupling abilities of these reconstituted kinetochores using an optical trap and demonstrate that there are two distinct and essential paths of force transmission through the inner kinetochore. These two paths, one through CENP-QU^{OA} and the other through CENP-C^{Mif2}, are stronger in combination than alone. Moreover, our work corroborates the finding that the Mis12c^{MIND}-inner kinetochore interface is regulated by the major mitotic kinase, Aurora B, which alleviates autoinhibition within Mis12c^{MIND}. Intriguingly, these two paths of force transmission through the inner kinetochore appear differentially sensitive to Aurora B phosphorylation. Taken together, this work represents a major advance towards the goal of reconstituting a complete, functional kinetochore from purely recombinant proteins.

P233/B239

Set, Pp2a Inhibitor, Fine-tunes Aurora B Kinase Activity at Centromere in a Tension-dependent Manner for Proper Chromosome Segregation.

Y. Asai, K. Fukuchi, R. Matsumura, Y. Terada; Waseda University, Tokyo, JAPAN.

Aurora B (AurB) kinase phosphorylates kinetochore substrates to destabilize improper kinetochore-microtubule (KT-MT) attachments, whereas the opposing phosphatase PP2A dephosphorylates these substrates to stabilize correct attachments. Thus, spatiotemporal phosphor-regulation at kinetochore is essential to establish chromosome bi-orientation and prevent aberrant chromosome segregation and aneuploidy, a hallmark of cancer. However, little is known about the molecular mechanism that tunes

the balance of phosphorylation at kinetochore. A proto-oncogene SET, a PP2A inhibitor, is well known to overexpress in many cancers, but the mechanism by which SET overexpression induces malignancy remains largely unknown. Here, we show that SET fine-tunes AurB kinase activity in a distance-dependent manner among sister kinetochores to regulate accurate chromosome alignment. In prometaphase (low tension), SET localized at centromere through direct interaction with Shugoshin2 maintains AurB activity by inhibiting PP2A. However, in metaphase (high tension), SET dissociation from centromere stabilizes bi-oriented attachments by activating PP2A, which results in decrease of AurB activity. These data suggest that a distance-dependent feedback loop between SET, Aurora B and Bub1 functions as a tension sensor at the centromere/kinetochore, and overexpression of SET promotes aberrant chromosome segregation and aneuploidy by inducing dysregulation of AurB. The following results suggest our conclusions. 1. In prometaphase, SET maintains AurB activity at centromere to regulate chromosome alignment. SET depletion or its overexpression, but not the overexpression of the mutant defective for interaction with Shugoshin2 at centromeres, affect AurB activity, and thereby induces chromosome misalignment and aneuploidy. 2. In prometaphase, centromeric pools of both AurB and Shugoshin2/SET are regulated by Bub1 at kinetochores through Bub1-mediated phosphorylation on HH2A at Thr-120. Similarly, AurB regulates Bub1 pools at kinetochore, suggesting a positive feedback loop between the amounts of SET and Bub1, and AurB. 3. In metaphase, SET dissociates from centromeres, depending on decrease of Bub1 pool at kinetochores, which results in stabilization of bi-oriented attachments by activating PP2A and inactivating AurB. P234/B240

A Universal Mechanism Underlying Impaired Centromeric Cohesion in Cancer Cells.

L. Yang; Tulane University, New Orleans, LA.

Centromeric cohesion is essential for proper chromosome segregation. Impaired centromeric cohesion are often found in cancer cells. The defects may contribute to chromosome instability and aneuploidy, which are major hallmarks for cancer. However, the mechanisms that underlie impaired centromeric cohesion in cancer cells are poorly understood. We and others recently showed that SET, a potent phosphatase 2A (PP2A) inhibitor, is also an inhibitor to the essential cohesion protector, Shugoshin. In a screening for SET protein levels in nearly 30 cell lines from various types of cancers, we found that most of the cancer cells exhibited much higher levels of SET than the non-transformed cell RPE-1, which is consistent with the results from various previous studies. Interestingly, we also found that the high levels of SET protein are positively related to centromeric cohesion defects in these cancer cells. Partial knock-down SET protein levels significantly rescued the centromeric cohesion defects for these cancer cells. Thus, highly expressed SET is a major factor that contributes to the impaired centromeric cohesion in cancer cells. As SET is also PP2A inhibitor and PP2A activity is often repressed in cancer cells, we also addressed whether lower PP2A activity is also responsible for the impaired centromeric cohesion in cancer cells. Surprisingly, we found that pharmaceutically increasing PP2A activity in these cancer cells did not ameliorate centromeric cohesion, suggesting that compromised PP2A activity in cancer cells may not be one of the major driving forces for impaired centromeric cohesion. Based on these findings, we propose that highly expressed SET in cancer cells contributes to impaired centromeric cohesion defects mainly through inhibiting Sgo1 functions not through inhibiting PP2A activity. As the phenomenon has been found in many types of cancer cells, we also propose that it is a major and universal mechanism underlying impaired centromeric cohesion in cancer cells.

P235/B241

Separase Cleaves the Kinetochore Protein Meikin to Direct the Meiosis I/II Transition.

N. K. Maier[1], J. Ma[2], S. Rusin[3], A. Kettenbach[3], M. Lampson[2], I. Cheeseman[1]; [1]Whitehead Institute of Biomedical Research, Cambridge, MA, [2]University of Pennsylvania, Philadelphia, PA, [3]Geisel School of Medicine at Dartmouth, Hanover, NH.

Meiosis is a specialized cell division that reduces the genetic content of a cell by half through two successive rounds of cell division. To achieve a reductional division during meiosis I, sister kinetochores must co-orient to transduce forces to the same spindle pole. In addition, cohesin in the centromeric region must be protected from cleavage by the protease Separase to ensure that sister chromatids remain associated until anaphase of meiosis II. Following the completion of meiosis I, it is critical to reverse both of these modifications to the cell cycle machinery to enable an equational division during meiosis II. The vertebrate protein Meikin regulates meiosis I co-orientation and centromere cohesion. However, the molecular basis for Meikin's contribution to meiosis remains poorly understood. In particular, the mechanism by which Meikin is inactivated during exit from meiosis I to reverse its activities is unclear. Here, we identify a conserved Separase target site in Meikin that directs Meikin cleavage at anaphase I onset. To determine the consequences of this cleavage event, we analyzed the sequence requirements for Meikin's interaction with kinetochores and regulatory components. We identify motifs in Meikin that are necessary and sufficient for kinetochore localization through an interaction with the inner kinetochore protein CENP-C and define the basis for its interaction with the cell cycle kinase Polo-like kinase 1 (PLK1). Our findings demonstrate that Separase cleavage separates these key domains abolishing Meikin-based regulation of PLK1 activity. Importantly, we find that Separase-resistant Meikin is retained at kinetochores until meiosis II in mouse oocytes, and oocytes expressing Separase-resistant Meikin display defective chromosome alignment during meiosis II consistent with incorrect sister kinetochore orientation. These data demonstrate that Meikin is a novel meiotic Separase substrate and indicate that Separase activity constrains Meikin localization and activity to meiosis I, thus allowing proper meiosis II chromosome segregation.

A Degron-based Strategy Reveals Processes Dependent on Aurora B Kinase Activity in *C. Elegans*.

N. Divekar[1], A. Davis-Roca[1], L. Zhang[2], A. Dernburg[2], S. Wignall[1]; [1]Northwestern University, Evanston, IL, [2]UC Berkeley, Berkeley, CA.

The conserved kinase Aurora B facilitates many important events during cell division. While numerous Aurora B substrates have been identified, some functions of Aurora-family kinases do not require kinase activity. Thus, understanding this key class of cell division regulators requires strategies to distinguish kinase-activity dependent and independent functions. We have developed a new degron-based approach that addresses this need, yielding new insights into how Aurora B facilitates cell division in *C. elegans. In C. elegans*, Aurora B (AIR-2) and other members of the chromosome passenger complex (CPC) are required for chromosome segregation and cytokinesis during both mitosis and oocyte meiosis. Moreover, the CPC is required for the assembly of an essential meiotic protein complex that forms a ring around the center of each chromosome in oocytes. This ring complex (RC) consists of over fifteen proteins, and AIR-2 is thought to serve as a scaffold upon which other RC proteins assemble. Furthermore, SUMOylation of some RC components enables the recruitment of others with SUMO-

interacting motifs (SIMs); since AIR-2 can be SUMOylated in *vitro*, AIR-2 SUMOylation could act as an early step in building this SUMO-SIM network (1). However, whether AIR-2's kinase activity is also important for RC assembly or for any of its other meiotic or mitotic functions is not known. Using our degron-based strategy, we inhibited the kinase activity of AIR-2 in *vivo* and determined that its kinase activity is essential for proper RC assembly, demonstrating that AIR-2 does not solely play a scaffolding role in the complex. In conditions where only kinase-dead AIR-2 was present, other CPC components loaded onto chromosomes but were unrestricted to the ring region, demonstrating that kinase activity is required for proper CPC patterning. Additionally, SUMO and SUMO-dependent RC components were absent from the chromosomes. Instead, we observed SUMO aggregates around the spindle, suggesting a role for AIR-2-dependent phosphorylation in the SUMOylation pathway and in SUMO-dependent RC assembly. Finally, we found that AIR-2's kinase activity is required for the proper assembly of the oocyte spindle, independent of AIR-2's role in RC formation, and for chromosome segregation during both meiosis and mitosis. Thus, our studies have revealed that AIR-2 kinase activity is required for multiple essential events in *C. elegans*, providing new insights into how Aurora B regulates cell division. In the future, this strategy can be applied to additional proteins, setting the stage for analogous studies of other essential kinases required for cell division. 1) Pelisch et al. (2017), *Molecular Cell*.

Regulation of Aurora B Kinase Activity by Chromosome Passenger Complex Coacervates.

T. Truong, 22903; University of Virginia, Charlottesville, VA.

It is unclear how cells initiate kinase signaling at the correct time and place. The inner centromere is a region of every mitotic chromosome that imparts unique functions, including mitotic signaling, cohesion, and the building of chromatin that can withstand the pulling forces of kinetochore microtubules. The chromosome passenger complex (CPC) is abundantly localized to the inner centromere in mitosis where it is critical for chromosome segregation and cytokinesis. The CPC is a hetero-tetrameric complex composed of INCENP, Survivin, and Borealin as well as the autoactivating kinase, Aurora B. We have recently found that the Borealin subunit has liquid demixing properties and drives the formation of a non-membranous organelle at inner centromeres. We suggest that the initiation of kinase signaling requires concentration of kinases inside non-membranous organelles, which stimulates kinase activity. In order to test this hypothesis, we are investigating how Aurora B kinase activity is affected by Borealin-mediated phase separation in *vitro*. We have initially focused on a system that physically separates the phase-separating and kinase subcomponents of the CPC. The N-terminus of INCENP, Survivin, and Borealin (ISB) phase-separate at concentrations below those found at inner centromeres. These coacervates recruit a complex of Aurora B and the C-terminus of INCENP (AI). Our system utilizes an Aurora B-specific PhosphoSens® substrate that is found both inside and outside coacervates at relatively similar concentrations and can be used to follow kinase activity, in real time. We have found that ISB coacervates promote the kinase activity of both AI and CPC when compared to similar concentrations of an ISB mutant that is deficient at coacervate formation. We think this is an allosteric activation since we are starting with a fully active kinase. We will use this system to follow kinase autoactivation and stimulation by cofactors including RNA, chromatin, and microtubules.

P238/B244

Function of Microtubule Binding by the Chromosomal Passenger Complex in Chromosome Biorientation.

T. Marsoner, C. S. Campbell; MFPL, Vienna, AUSTRIA.

One of the key steps during cell division is the attachment of sister chromatids to opposite spindle poles, a process called chromosome biorientation. Sister chromatids are attached to the microtubule-based spindle via the kinetochore, which is a multiprotein network forming at the centromeric region of chromosomes that establishes direct microtubule attachments. Chromosome biorientation is a stochastic process. Initially many erroneous kinetochore microtubule attachments are formed where both sister chromatids are attached to microtubules emanating from the same spindle pole (syntelic attachment). If not efficiently detected and corrected, such syntelic arrangements lead to chromosome missegregation resulting in an unequal distribution of chromosomes. An increased rate of chromosome missegregation (chromsomal instability or CIN) cause aneuploidy, which is detrimental for the cell. In order to maintain a stable genome, the conserved chromosomal passenger complex (CPC) detects and corrects such syntelic attachments during prometaphase. If the CPC encounters a syntelic arrangement, the kinase subunit Aurora B (Ipl1 in yeast) phosphorylates key kinetochore targets leading to detachment of the microtubule so that a new, correct attachment may be formed. Although the CPC phosphorylates the kinetochore in prometaphase, the CPC is mainly localized at the inner centromere until anaphase onset, at which point it relocalizes to the mitotic spindle. Previously, we and others have shown that the centromere localization is dispensable for CPC function in yeast and chicken cells. Interestingly the microtubule localization is essential for chromosome biorientation. In this work we aim to determine the function of CPC microtubule localization in chromosome biorientation. To do so, we focus on the CPC scaffold protein INCENP (Sli15 in yeast), which is responsible for CPC localization via its centromere targeting domain (CEN-box) as well as its microtubule binding domain (MTB). Engineering different MTB mutants, we found that the MTB is necessary for CPC function. Surprisingly, microtubule binding is not sufficient, suggesting an additional function of the MTB.

P239/B245

Identification of Suppressors of Chromosomal Passenger Complex Mutants in Budding Yeast.

M. N. Clarke, M. C. Ravichandran, R. Schwarzmayr, C. S. Campbell; Max Perutz Labs, Vienna, AUSTRIA.

The chromosomal passenger complex (CPC) is responsible for destabilizing incorrect kinetochore-microtubule attachments. Without a functional CPC, microtubule-kinetochore attachments become over stabilized and high levels of missegregation (also known as chromosomal instability or CIN) are induced. CIN leads to aneuploidy and induces loss of proliferation. Even though CIN inhibits growth, many cancers exhibit high levels of CIN and aneuploidy. How cancer becomes tolerant to CIN, despite it being detrimental to normal cells, is still largely unknown. To probe the mechanisms that assist adaptation to CIN, multiple *S. cerevisiae* strains were created that lack the CPC subunit *BIR1,* thus inducing persistent CIN. The bir1Δ strains were then given time to adapt to persistent CIN in liquid culture, and Next-Generation Sequencing was used to identify a number of suppressor mutants of the bir1Δ phenotype. Suppression of the bir1Δ phenotype was confirmed by introducing the mutations prior to *BIR1* deletion. Four categories of suppressor mutants were identified. The first group of bir1Δ suppressor mutants are in the outer kinetochore proteins, including multiple members of the Dam1 complex. Results suggest that this first group of suppressors act at the most downstream part of the kinetochore-microtubule

error correction pathway. The second group of suppressors were in the Spindle Assembly Checkpoint kinase. Like mutants of the CPC, loss of *MPS1* function leads to syntelic-attachments and chromosome missegregation. It is therefore quite surprising that compromising *MPS1* activity would suppress, rather than enhance, the CPC mutant phenotype. The third group of suppressors are in subunits of the SCF ubiquitin ligase complex, which controls entry into S-phase and mitosis. There is currently no known function for the SCF complex in regulating kinetochore microtubule attachments. The last group of suppressor mutants were found in the CPC itself. Interestingly, all these suppressor mutants are in essential genes, indicating that the alleles are either hypomorphic or gain-of-function. These suppressors may help adaptation to CIN through destabilization of the over stabilized kinetochore-microtubule attachments caused by disruption of the CPC. This model is currently being tested by microscopy.

Structural Characterisation of KKT4: an Unconventional Kinetochore Protein.

P. Ludzia, C. Redfield, B. Akiyoshi; Department of Biochemistry, University of Oxford, Oxford, UNITED KINGDOM.

A key structure involved in the process of chromosome segregation in eukaryotes is the kinetochore, a proteinaceous complex that mediates the interaction between centromeric DNA and spindle microtubules. Although it was widely assumed that kinetochore components are conserved across all eukaryotes, a unique set of kinetochore proteins was discovered in an evolutionarily-divergent group of organisms called kinetoplastids. No significant similarity to conventional kinetochore proteins is found in these kinetoplastid kinetochore proteins (KKT1-20 and KKIP1-7), and very little is known about their function and structure. Recently we reported KKT4 as the first kinetochore protein in *Trypanosoma brucei* that has microtubule-binding activities. Here we show that its microtubule-binding domain consists of an N-terminal coiled-coil fold and a disordered C-terminal tail that enhances microtubule-binding activities. Interestingly, we discovered that in addition to microtubule-binding activities KKT4 also has DNA-binding activities. Therefore, KKT4 is a unique kinetochore protein in eukaryotes, binding both DNA and microtubules. By analysing KKT4 protein, we aim to understand how the unconventional kinetoplastid kinetochores interact with microtubules to facilitate faithful chromosome segregation.

Crispr-cas9-based Tiling Screens Reveal Protein Domain Structure and Novel Functional Regions in Human Mitotic Factors.

J. Herman, L. Carter, S. Biggins, P. Paddison; Fred Hutchinson Cancer Research Center, Seattle, WA.

A critical knowledge gap for the human genome has arisen from our inability to resolve important functional domains and motifs within protein coding genes at the large scale. Historically, large scale annotation of protein domains and motifs relied on homology based-inference by searching against the current 5494 conserved protein family (Pfam) domains documented in the human genome (e.g., methyltransferase-like domain). This approach is ineffective for the ~45% of the proteome that is devoid of Pfam domains, and still requires validation for the remaining genes. Closing this knowledge gap is critical for both basic and disease-focused biomedical research, where years, if not decades, can be spent dissecting gene functions. Here we leverage the mutagenic properties of CRISPR-Cas9 by saturating sgRNAs across the coding sequence of a gene to identify essential domains and motifs. A

panel of diploid and aneuploid cells suggest critical, phenotypically constrained regions do not tolerate in-frame CRISPR-Cas9 indels. As a result, each gene produces a unique mutational signature, with constrained regions scoring as phenotypic "peaks". As a test case, we performed tiling mutagenesis to resolve the domain structure for 48 well characterized kinetochore-associated genes and identified approximately 160 functional regions, of which nearly 1/4 have not been previously described. Novel regions were found in a diverse set of mitotic factors including: SKA3, Rod, Spindly, Shugoshin, Mad1, and chTOG and preliminary evidence suggests many of them contribute to protein-protein interactions responsible for sub-cellular localization. This powerful genetic approach allows rapid and inexpensive dissection of essential protein activities expanding our understanding of genic structure for application to both basic science and disease-focused questions.

Human Alpha1-antitrypsin Intracellular Form Enriches the Nucleus in Interphase and Spindle/kinetochores in Mitotic Cells.

A. A. Maslakova[1], S. A. Golyshev[2], M. A. Rubtsov[3,4], O. V. Smirnova[1]; [1]Department of Human and an imal Physiology, Faculty of Biology, M.V. Lomonosov Moscow State University, Moscow, RUSSIAN FEDERATION, [2]A.N. Belozersky Institute of Physical and Chemical biology, M.V. Lomonosov Moscow State University, Moscow, RUSSIAN FEDERATION, [3]Department of Molecular Biology, Faculty of Biology, M.V. Lomonosov Moscow State University, Moscow, RUSSIAN FEDERATION, [4]Department of Biochemistry/Institute of Translational Medicine and Biotechnology, I.M. Sechenov First Moscow State Medical University (Sechenov University), Moscow, RUSSIAN FEDERATION.

Alpha1-antitrypsin (AAT) is a potential biomarker in many tumors. The protein level tends to rise in tumor patients. Not only the full-length AAT is associated with cancer progression, but also AAT-derived C-terminal peptides have been found in cancer patients biological fluids [Cercek L & Cercek B, 1992; Chang WC et al., 2008; Zhou J et al., 2010]. One of the established roles of these peptides is the suppression of cytotoxic immune cells in favor of tumor progression [Cercek L & Cercek B, 1993; Kataoka H et al., 1999]. Sporadic findings also showed that AAT could be retained in the cytoplasm of the transformed cells [Normandin K et al., 2010; Shapira MG et al., 2014]. We hypothesized that cancer cells produce intracellular AAT forms (full-length or the C-terminal peptides) along with the secretory counterpart since the dual localization of secretory proteins is an established phenomenon. Here we investigated the DU145 cell line by immunofluorescence using antibodies against the full-length AAT molecule and its C-terminus. Both antibodies reveal protein accumulation in the nucleus, predominantly in euchromatin and the interchromosomal space, but not in the nucleoli and heterochromatin. When cells progress into mitosis, the fraction of AAT detected exclusively by anti-C-terminal antibodies arises as a *bona fide* component of the outer kinetochore, that can be visualized after cell permeabilization. The full-length AAT anchors to the mitotic spindle and spindle poles. We have found that this AAT intracellular distribution is RNA-dependent, so the non-secretory AAT is the RNA- or RNP-binding protein. Since the AAT C-terminal domain has a strongly basic pI in contrast to the rest AAT molecule and contains the predicted RNA-binding motif, we assume that this domain is crucial for exerting AAT functions inside the cell. Indeed, after cell permeabilization, we demonstrated that TAMRA-labeled C36, the synthetic AAT C-terminal peptide, enriches the nucleus, especially the nucleoli, in the interphase cells, and mitotic spindle/spindle poles in the dividing cells, - in contrast to the Cy3-labeled AAT from blood plasma. Although the precise role of intracellular AAT in the cell cycle is to be elucidated, we believe that our study reveals the new facet of AAT functions. The study was supported by RFBR project

Modeling Chromosome Dynamics and Mitotic Cell Fate Decision in 3d Using Organoids and Mitotic an tagonists.

J. Li[1], X. Liu[1], M. Mullen[2], T. Ward[2], **X. Yao**[1], X. Liu[1]; [1]Cellular Dynamics, Hefei, CHINA, [2]Morehouse School of Medicine, Atlanta, GA.

Error-free cell division depends on the accurate assembly of the spindle midzone from dynamic spindle microtubules to ensure chromatid segregation during metaphase-anaphase transition. However, the mechanism underlying the key transition from the mitotic spindle to central spindle before anaphase onset remains elusive. Given the prevalence of chromosome instability phenotype in gastric tumorigenesis, we developed a strategy to model context-dependent cell division using a combination of light sheet microscope and 3D gastric organoids. Light sheet microscopic image analyses of 3D organoids showed that BubR1 and CENP-E inhibited cells undergoing aberrant metaphase-anaphase transition and exhibiting chromosome segregation errors during mitosis. Using a selective BubR1 kinase antagonist Bubristatin, we found that inhibition of CENP-E phosphorylation is shown to prevent proper microtubule capture at kinetochores and, surprisingly, proper assembly of the central spindle at mitotic exit. These findings reveal a previously uncharacterized role of BubR1-elicited phosphorylation of CENP-E in temporal control of central spindle assembly.

P244/B250

Meiotic Drive of Non-centromeric Locus R2d2 in Mouse Oocytes.

T. Akera[1], E. Trimm[2], M. A. Lampson[2]; [1]NIH, National Heart, Lung, and Blood Institute, Bethesda, MD, [2]University of Pennsylvania, Philadelphia, PA.

Mendel's Law of Segregation states that each allele has an equal chance to transmit to the gametes. However, this law can be violated by selfish genetic elements, which manipulate the production of gametes to increase their own rate of transmission. This genetic cheating in meiosis, meiotic drive, is typically associated with fitness cost to the host and has significant impacts on genetics, evolution, and reproduction. In female meiosis, selfish elements bias their transmission by preferentially segregating to the egg. We focus on selfish R2d2, a non-centromeric locus on mouse chromosome 2, which shows over 90% transmission ratio distortion with mild embryonic lethality. The underlying cell biological basis for both biased segregation and the embryonic lethality is unknown. Here, we developed a strategy to track the R2d2 locus by live imaging in mouse oocytes and found that the chromosome with R2d2 locus lags in anaphase. An aphase lagging could induce biased segregation in oocytes, because the majority of the cytoplasm remains in the egg after polar body extrusion. An aphase lagging would also cause aneuploidy in the egg, leading to embryonic lethality. Therefore, this simple model has a potential to explain the mechanisms underlying both meiotic drive and the associated fitness cost.

P245/B251

Meiosis-Specific Aurora Kinase B Function in Regulating Protein Levels in Mouse Oocytes.

M. Aboelenain[1,2], J. Favate[1], P. Shah[1], K. Schindler[1]; [1]Department of Genetics, Human Genetics Institute of New Jersey, Rutgers, the State University of New Jersey, Piscataway, NJ, [2]Department of Theriogenology, Faculty of veterinary medicine, Mansoura University, Mansoura, EGYPT.

In mitosis, Aurora kinase B is an essential regulator of the chromosomal passenger complex required for successful chromosome segregation. In mouse oocytes, which are completing meiosis I, Aurora kinase C appears to take over this CPC role and carry out AURKB mitotic-like functions. We previously demonstrated AURKB is required to negatively regulate AURKC, and this negative regulation is required to prevent aneuploidy. How AURKB negatively regulates AURKC is unknown. Oocyte meiosis and early embryo development occur in absence of transcription and depend on the translational activation of accumulated and stored maternal mRNAs. Because transcription is silent during meiosis, we hypothesized that AURKB affects either protein translation and/or protein stability to negatively regulate AURKC. Using a Click chemistry-based translation assay, we found a significant increase in total translation in *Aurkb*knockout (KO) oocytes compared to WT. These findings suggest that AURKB negatively regulates translation during mouse oocyte meiosis.Translation in mouse oocytes is regulated, in part, through the presence of cytoplasmic polyadenylation elements (CPE) located within the 3'UTRs of stored maternal RNAs. The cytoplasmic polyadenylation element binding protein (CPEB1) is responsible for CPE-mediated translation. CPEB1 is then phosphorylated and is mainly turned-over after completion of meiosis I. This phosphorylation is also required for CPEB1 function. We found that CPEB1 is less stable in *Aurkb*KO oocytes compared to WT. In an attempt to identify differentially translated messages that could be driving the aneuploidy phenotype, we isolated polysome-bound RNAs from WT and *Aurkb*KO oocytes. We found an enrichment of RNAs with 2 or more CPEs in their 3'UTR in*Aurkb*KO oocytes. This enrichment suggests that AURKB negatively regulates messages that are highly translated in a CPE-dependent manner. Interestingly, we also found a decrease in ribosome-bound RNAs of proteins with function related to ubiquitylation/ protein degradation pathways, suggesting alterations in protein stability.In conclusion, this study suggests that AURKB can regulate translation and/or protein degradation during oocyte meiotic maturation, events critical to generating euploid eggs.

P246/B252

Retinoblastoma Protein Absence in Human Cells Induces Genomic Instability and Affects Kinetochore Structure.

A. Stingi, P. Meraldi; University of Geneva, geneva, SWITZERLAND.

The Retinoblastoma protein 'pRB' is a tumor suppressor, encoded by the RB1 gene. pRB repress genes involved in DNA replication and blocks the G1/S transition. A large percentage of human cancers bear mutations in the pRB pathway, resulting in uncontrolled cell proliferation. In addition to this well-characterized role, RB loss has been also implicated in genomic instability, another cancer hallmark, as it leads to gain or loss of chromosomes in mitosis. The mechanisms underlying this mitotic phenotype are, however, not well understood. Our goal is to better understand role the role of pRB in genomic instability. Here we achieved an 80% reduction in pRB expression by RNAi in RPE1 cells, a non-transformed cell line derived from human Retinal Pigmented Epithelium. pRB depletion increased the duration of mitotic timing and increased the incidence of lagging chromosomes after a monastrol-release, highlighting its contribution to genomic instability. Lagging chromosomes can arise from

deregulated kinetochore-microtubule attachments, defective kinetochore structure or incomplete DNA condensation. Using live-cell imaging-based assays we find that microtubules-kinetochore attachments and DNA condensation were not affected by pRB depletion. In contrast, acute pRB depletion lowered the levels of CENP-A at centromeres, the centromeric histone required for the assembly of kinetochores. Our experiments further suggest that this reduction in CENP-A levels, does not affect kinetochore-attachments directly, but correlates with a reduced ability to correct erroneous kinetochore-microtubule attachments. Interestingly it was recently was reported that human cancer lacking pRB are more sensitive to inhibitors against the Aurora B kinase, a key component of the machinery correcting erroneous kinetochore-microtubule attachments. Our future aim is to test whether this increased sensitivity is due to lower CENP-A levels.

P247/B253

Evidence That CENP-B and CENP-C Suppress Biased Segregation of Selfish Centromere DNA in Female Meiosis.

T. Kumon, J. Ma, D. Stefanik, E. C. Nordgren, R. B. Akins, J. Kim, M. Levine, M. A. Lampson; University of Pennsylvania, Philadelphia, PA.

Centromere evolution is paradoxical in that both centromere DNA and proteins are rapidly evolving despite the conserved requirement of centromeres for faithful chromosome segregation. The centromere drive hypothesis proposes that maternal and paternal centromeres compete for the egg during female meiosis, and selfish centromere non-coding DNA is evolving to achieve preferential inheritance over the homologous counterpart. Under this hypothesis, centromere proteins recurrently evolve to suppress the fitness cost imposed by centromere DNA cheating. To study centromere drive, we have established a hybrid mouse model (a cross between *Mus musculus domesticus* strains) where centromeres from one strain achieve preferential inheritance over centromeres from the other strain. We hypothesized that selfish centromere DNA recruits more CENP-B, the only known centromere-specific DNA binding protein, to achieve preferential inheritance. In contrast to this initial expectation, CENP-B knock-out and over-expression in our hybrid mice suggested that CENP-B suppresses centromere drive. In order to identify other candidate suppressors of drive, we conducted a molecular evolution analysis that detects signatures of rapid evolution. Limited availability of mouse genomes resulted in low-quality data, motivating us to sequence other Murinae species. CENP-C scored highly in the analysis, and over-expression of rat CENP-C in our hybrid mouse model for drive prevented preferential segregation of selfish mouse DNA in meiosis I. This result suggests that centromere DNA directly recruits CENP-C, and CENP-C evolved to “escape” from centromere DNA. Our combined approach of evolutionary analysis and cell biological experiments support the idea that both CENP-B and CENP-C suppress selfish centromere DNA drive.

P248/B254

Ndc80 Complex Is Essential for the Initial Kinetochore-microtubule Capture during Early Mitosis.

D. Varma, M. A. Amin; Northwestern University Feinberg School of Medicine, Chicago, IL.

The capture of sister kinetochores by the spindle microtubules (MTs) is essential to form proper kinetochore-microtubule (kMT) attachments that drive chromosome alignment and error-free chromosome segregation. It was reported that kinetochores are initially captured in early mitosis by dynamically unstable MTs (Mitchison and Kirschner, 1984) which are then stabilized to promote bipolar

spindle formation by a 'search-and-capture' mechanism (Kirschner and Mitchison, 1986). During early mitosis, outer surface of unattached kinetochores transiently expand outward to form a fibrous corona, and associate laterally with the sides of the MTs (Barisic et al., 2014; Kapoor et al., 2006; Magidson et al., 2011; McEwen et al., 1998; Rattner and Bazett-Jones, 1989; Ris and Witt, 1981; Tanaka et al., 2005). In humans, MT-based minus-end-directed motor dynein has been reported to transport laterally-attached chromosomes towards the spindle pole (Li et al., 2007; Rieder and Alexander, 1990; Vorozhko et al., 2008; Yang et al., 2007). The Hec1 subunit of the kinetochore-bound Ndc80 complex has direct MT-binding activity and has been demonstrated to play a central role in stabilizing kMT attachments during mitotic metaphase (Cheeseman and Desai, 2008; Miller et al., 2008; Santaguida and Musacchio, 2009; Wei et al., 2007). However, the precise mechanism of how the different kinetochore MT-binding factors contribute to initial kinetochore capture by MTs during early mitosis is still unknown. By combining genome editing and RNAi approaches, we show that mitotic cells lacking the Ndc80 complex exhibit severe defects in capture of kinetochores by MTs during early mitosis. Further, the kinetochore capture mediated by Ndc80 depends on Aurora B kinase-mediated phosphorylation of its N-terminal unstructured tail domain and the normal functionality of the calponin homology (CH) domain as we find that the respective mutants of Ndc80 are unable to rescue the defects in the capturing of kinetochore by MTs. These findings reveal a previously unappreciated and essential role of Ndc80 complex in initial kinetochore capture by MTs during early mitosis, which in turn is required for proper chromosome congression, alignment and segregation.

Cargo Motive Force Is Decoupled from ParA Gradient Maintenance in the F Plasmid ParABS Partition System.

J. A. Taylor[1], Y. Seol[2], K. C. Neuman[2], K. Mizuuchi[1]; [1]NIDDK, Bethesda, MD, [2]NHLBI, Bethesda, MD.

ParABS DNA partition systems ensure faithful segregation of many bacterial chromosomes and low-copy number plasmids. To gain greater insight into the mechanism of these systems, we characterized F-plasmid $ParA_F$—$ParB_F$ protein complexes bound to DNA in the presence of ATPγS using TIRF microscopy. The proteins formed a complex with a 1:1 ratio in the absence of $parS_F$, a centromere-like DNA sequence to which $ParB_F$ binds, but the $ParB_F$:$ParA_F$ ratio doubled in the presence of $parS_F$. This change in ratio did not occur with a $ParB_F$ bearing a mutation in the conserved Box II region, despite $parS_F$-binding being unaffected. The activation efficiency of the DNA-bound $ParA_F$-ATPase by $ParB_F$ was also enhanced by $parS_F$ in a Box II-dependent manner. A monomeric protein carrying only the $ParA_F$-interaction domain of $ParB_F$ activated $ParA_F$ ATPase cooperatively, and formed a 1:1 complex with $ParA_F$. Based on these observations we propose that local $ParA_F$—$ParB_F$ association-dissociation dynamics are partially uncoupled from the slow ATPase step by an activation energy barrier involving a conformational change within the $ParA_F$—$ParB_F$ complex. This would result in decoupling of the generation of the plasmid cargo motive-force via $ParA_F$—$ParB_F$ interactions from the ATPase step that maintains the $ParA_F$-ATP concentration gradient essential for directed motion.

P250/B256

Chromosome Detachment from the Nuclear Envelope Is Required for Genome Stability in Closed Mitosis.

R. Chen; Academia Sinica, Taipei, TAIWAN.

Mitosis in metazoans involves detachment of chromosomes from the nuclear envelope (NE) and NE breakdown, whereas yeast maintains the nuclear structure throughout mitosis. It remains unknown how chromosome attachment to the NE might affect chromosome movement in yeast. By using a rapamycin-induced dimerization system to tether specific locus of the chromosome to the NE, I found that the tethering delays the separation and causes missegregation of the region distal to the tethered site. The phenotypes are exacerbated by mutations in kinetochore components and Aurora B kinase Ipl1. The chromosome region proximal to the centromere is less affected by the tether, but it exhibits excessive oscillation before segregation. Furthermore, the tether impacts full extension of the mitotic spindle, causing abrupt shrinkage or bending of the spindle in shortened anaphase. The study supports that detachment of chromosomes from the NE is required for faithful chromosome segregation in yeast and that segregation of tethered chromosomes is dependent on fully functional mitotic apparatus.

Increased Chromosome Speeds in the Absence of Microtubules In*Mesostoma Ehrenbergii* Spermatocytes May Be Due to Actin and Myosin in the Spindle.

E. Fegaras, A. Forer; York University, Toronto, ON, CANADA.

We study chromosome movement in *Mesostoma ehrenbergii* primary spermatocytes to understand what produces the forces for movement. In this cell there are three bivalents which extend across the center of the cell, and four univalents of two different types, 2 metacentrics and 2 acrocentrics (Ferraro-Gideon et al. 2014; Fuge 1987,1989). In previous work, we described experiments in which chromosome kinetochores moved rapidly towards one single pole in the absence of microtubules (Fegaras and Forer 2018 a and b). After 10µM nocodazole (NOC) depolymerized prometaphase spindle microtubules, all chromosomes detached from one pole and rapidly moved to the other pole at speeds up to 200 µm/min. Since chromosomes stretch out in NOC before detaching, the rapid chromosome movements in the absence of microtubules might conceivably be due to recoil from the tension. We argued that this movement is not due to recoil because chromosomes do not move in a straight line between the two kinetochores (Fegaras and Forer 2018 a), but to test this further, we cut 1, 2, or all 3 bivalents into 2 pieces using a femtosecond laser, both before and during addition of NOC. After treatment with NOC, the kinetochores of the severed bivalents still moved to one pole, at speeds similar to non-severed chromosomes. Since movement is not due to either microtubules or tension, we suggest it may be due to actin and myosin in the spindle, as found in other cells (Forer et al., 2015; Mogessie and Schuh 2017). Perturbation of myosin and actin alters bivalent oscillation speeds in *Mesostoma* (Silverio 2017), and our data implicate actin and myosin in the rapid NOC-induced chromosome movement: after treatment of cells with NOC, inhibitors decreased chromosome speed and increased time to detachment, whereas enhancers increased chromosome speed and decreased time to detachment. In future experiments, we will test this conclusion by staining for myosin, phosphorylated myosin, and actin after the addition of NOC, to see if they are in contact with the moving chromosomes. We will also study these proteins in

not-treated cells to determine if they are asymmetrically positioned within the cell or oriented towards a particular pole.

Chromosome-specific Differences during Meiosis.

K. K. Billmyre[1], C. Cahoon[2], E. Wesley[3,1], R. Hawley[1]; [1]Stowers Institute for Medical Research, Kansas City, MO, [2]University of Oregon, Eugene, OR, [3]University of Missouri Kansas City, Kansas City, MO.

Chromosomal aneuploidy in oocytes is one of the leading causes of infertility and miscarriages in women. It has been well known for many years that chromosome missegregation during meiosis is responsible for producing aneuploidy, and that the rate of missegregation can drastically increase when recombination patterns are altered. Interestingly, aneuploidy rates have been shown to vary between chromosomes, indicating that each chromosome may have unique underlying biology that affects its behavior during various meiotic processes. It is unclear, however, what roles important meiotic complexes may play in regulating this chromosome-specific behavior. The synaptonemal complex (SC) is a conserved meiotic structure that regulates the repair of double-strand breaks (DSBs) into crossovers or gene conversions. Recently, we used CRISPR/Cas9 to create a set of targeted SC mutants in *Drosophila* that exhibit chromosome-specific recombination defects reminiscent of the altered recombination patterns seen in human trisomy. These mutants contain varying in-frame deletions within the same *Drosophila* SC protein, each of which resulted in fragmentation of the SC at three different times: early pachytene, early-mid pachytene, and mid pachytene. With this temporal resolution, we investigated when full-length SC is required for meiotic processes such as clustering of centromeres, pairing, and recombination on a chromosome-specific level. We found that the *X* chromosome displays different recombination phenotypes than the autosomes in response to disruptions in SC structure, suggesting crossover distribution is potentially regulated differently on the *X* chromosome versus the autosomes. We are currently working to uncover the mechanisms that underlie these chromosome-specific recombination defects using next-generation sequencing and super-resolution microscopy. These unique mutants allow us to investigate the role of the SC in regulating chromosome-specific meiotic processes.

The DNA Replication Factor PCNA Provides Directed Regulation of Cohesin Function.

C. Zuilkoski, R. V. Skibbens; Lehigh University, Bethlehem, PA.

Genomes undergo structural changes in response to transcriptional activation, DNA repair, chromosome condensation, and sister chromatin cohesion. The cohesin complex supports the formation of each of these various DNA architectures, though the mechanism through which cohesin functions are directed to these different chromatin states remains unknown. Prior findings support a role for DNA replication factors in regulating Eco1/Ctf7 (herein Eco1) function to activate cohesin. Early studies revealed that PCNA promotes Eco1 function such that elevated levels of PCNA rescue *eco1* mutant cell growth defects. More recently, PCNA was found to bind and become acetylated by Eco1. Here, we test the extent to which PCNA overexpression rescues phenotypes (cohesion defects, condensation defects, or both) exhibited by *eco1* mutant cells. Intriguingly, the cohesion defect, but not condensation defect, was rescued in *eco1* mutant cells, suggesting that PCNA promotes Eco1-dependent cohesion in a context-specific fashion at the DNA replication fork. Thus, the context of DNA replication is critical to promote

specific roles for Eco1 and cohesin in sister chromatin cohesion. Interestingly, though overexpression of PCNA rescues *eco1* mutant growth defects, excess PCNA exacerbates the growth of cells that harbor a mutation in the cohesin subunit *mcd1*/*scc1* (herein *mcd1*). The molecular basis of this negative genetic interaction remains unknown. One possibility is that elevated levels of chromatin-bound PCNA adversely impact cohesin loading and acetylation. Our results, however, reveal that excess PCNA does not adversely impact cohesin chromatin binding nor cohesin acetylation. Intriguingly, however, elevated levels of wildtype PCNA increases *mcd1* mutant cell sensitivity to DNA damage. These results reveal that PCNA promotes Eco1-dependent cohesion but increases cohesin mutant sensitivity to DNA damage agents. In combination, our results suggest that the context of DNA replication is critical to promote specific roles for cohesin in sister chromatin cohesion but that changes in DNA replication factors can have adverse effects on a subset of cohesin function.

P254/B260

Dna Damage-induced Transcription Reactivates Eco1 to Establish Cohesion.

M. Mfarej, R. Skibbens; Lehigh University, Bethlehem, PA.

The Eco1 acetyltransferase establishes sister chromatid cohesion during DNA replication before its degradation during late S phase that continues throughout M phase. In response to DNA damage in M phase, however, Eco1 is required to establish Damage-Induced Cohesion (DIC) which is critical for efficient DNA repair. To date, little evidence exists for how Eco1 is reactivated during M phase to establish cohesion during the DNA damage response. Popular models include that the degradation machinery that targets Eco1 is inhibited or that changes in post-translational modifications make Eco1 refractile to the degradation pathway. Surprisingly, our results reveal that the degradation machinery is fully competent in response to DNA damage during M phase. Thus, the modifications that target Eco1 for degradation at the end of S phase and throughout M phase persist despite DNA damage. Instead, our results document that DNA damage during M phase induces new transcription of *ECO1* and at a rate that exceeds the rate of Eco1 turnover, providing for Eco1 protein accumulation and DIC-based DNA repair. Eco1 reactivation during M phase is complex and dose-dependent, however, in that high levels of DNA damage fail to reactivate Eco1. Collectively, these findings document a novel regulatory pathway through which Eco1 reactivation occurs during M phase and in response to DNA damage, but that this DNA damage response pathway is complex and dose-dependent. This study highlights the complex nature through which mutations in cohesin or Eco1/ESCO promote developmental abnormalities and contribute to various diseases including cancer.

Self-dna Sensing by Cgas and Its Effect on Cell Fate during Mitotic Arrest.

C. Zierhut, N. Yamaguchi, M. Paredes, J. Luo, T. Carroll, H. Funabiki; the Rockefeller University, New York, NY.

cGAS is a major pattern-recognition receptor detecting cytoplasmic DNA for the innate immune system. Upon DNA binding, cGAS becomes an enzyme, synthesizing a cyclic GMP-AMP dinucleotide second messenger (cGAMP), which promotes inflammation via activation of IRF3- and NF-kB-dependent transcription. The primary substrate for cGAS is pathogen-derived DNA but the mechanisms by which cGAS distinguishes between self-DNA and non-self DNA are poorly understood. Furthermore, cGAS is also thought to respond to a subset of aberrant self-DNA structures such as micronuclei. We have shown

that the organization of eukaryotic nuclear DNA into chromatin may serve as a signal for self-DNA, inhibiting activation of cGAS. The basic unit of chromatin, the nucleosome, binds cGAS with higher affinity than does naked DNA, but nucleosomes competitively inhibit DNA-dependent cGAS activation. Thus, the cGAS pathway is not effectively activated during normal mitosis, when the nuclear envelope disassembles, exposing all chromosomal DNA to the cytoplasmic cGAS. However, during mitotic arrest, low level cGAS-dependent IRF3 phosphorylation slowly accumulates, promoting cell death rather than inflammation. Accordingly, expression of cGAS in cancer cells makes mouse xenograft tumors responsive to the anti-mitotic agent Taxol. TCGA datasets for non-small cell lung cancer patients also suggest an effect of cGAS expression on the taxane response. To determine the mechanism by which nucleosomes inhibit cGAS, we have investigated the biochemistry of the interaction between cGAS and nucleosomes. DNA-binding mutants of cGAS only mildly affect affinity for nucleosomes, suggesting an interaction between histones and cGAS. Indeed, cGAS directly associates with the histone H2A-H2B dimer in a manner dependent on the acidic patch of H2A-H2B, a hotspot for nucleosome interactors.

Gy Controls Meiotic Progression by a Phase Separation Mechanism during Spermatogenesis.

Z. Zhou; ShanghaiTech University, Shanghai, CHINA.

Meiosis is germ cell-specific cell division that generates haploid gametes in sexually reproducing organisms. During meiosis, environmental stresses can damage meiotic cells and lead to clinical infertility. It has long been observed that in cryptorchidism patients, undescended testes do not provide suitable temperature for spermatogenesis, consequently, meiotic spermatocytes are decreased. However, the molecular mechanism underlying this stress sensitive phenomenon is largely unknown. Here we report that liquid-liquid phase separation of a novel RNA binding protein GY, ensures both meiotic progression and cell fitness under stress conditions. Stress granules were constantly observed in the testes of cryptorchid patients. We found GY to be essential for heat stress-induced granule formation. We provide evidence that GY ensures the meiotic progression through two mechanisms: stabilization of target mRNAs to control translation of meiotic molecules; enhancement of cellular fitness of meiotic cells in stress conditions through an inherent phase separation mechanism. We propose that reversible phase separation of GY ensures meiotic synapsis in spermatocytes under stress conditions.

***Spindlin1* Regulates BUB3 Expression and Affects an aphase Transition during Meiotic Maturation in Porcine Oocytes.**

D. Zhou, J. Choi, W. Zhou, X. Cui; Chungbuk National University, Cheongju, KOREA, REPUBLIC OF.

Spindlin1 (*SPIN1*), which contains Tudor-like domains, regulates maternal transcripts via interaction with a messenger RNA (mRNA)-binding protein. *SPIN1* is involved in tumorigenesis in somatic cells and is highly expressed in the cancer cell. Nevertheless, the function of *SPIN1* in porcine oocyte maturation remains totally unknown. To explore the function od *SPIN1* in porcine oocyte maturation, knockdown, and overexpression techniques were used. *SPIN1* mRNA was identified in maternal stages ranging from GV to MII. *SPIN1* was localized in the cytoplasm and to chromosomes during meiosis. *SPIN1* knockdown accelerated first polar body extrusion. Oocytes with overexpressed *SPIN1* were arrested at the MI stage. *SPIN1* depletion caused meiotic spindle defects and chromosome instability. The BUB3 signal was

investigated, confirming that *SPIN1* affects the stability of *BUB3* mRNA as well as BUB3 expression. Further, overexpression of *SPIN1* inhibited the degradation and regulation of G2/mitotic-specific cyclin-B1. In summation, *SPIN1* regulates the meiotic cycle by modulating the activation of the spindle assembly checkpoint.

P258/B264

Set Binding to Sgo1 Inhibits Sgo-cohesin Interactions and Promotes Chromosome Segregation.

Y. Chen; Tulane University, New Orleans, LA.

At anaphase onset, Sgo1 function of cohesion protection must be disabled to allow timely chromosome segregation, but how this is achieved is not fully understood. Here, we show that SET, a known PP2A inhibitor, directly binds to a domain in Sgo1 in close proximity to the cohesin-binding motif. The Sgo1-cohesin binding can be disrupted by SET in a dose-dependent manner in vitro as well as by SET overexpression in cells, suggesting that SET is also an inhibitor to the Sgo1-cohesin binding. Furthermore, the SET binding-deficient Sgo1 mutant fully supports centromeric cohesion protection but delays chromosome segregation, suggesting that the SET-Sgo1 binding is required for timely chromosome segregation. Moreover, overexpression of SET WT, not the Sgo1 binding-deficient mutant, exacerbates the occurrence of cohesion fatigue in MG132-arrested cells. Conversely, SET depletion delays it. Thus, we propose that a major function of SET during mitosis is to disrupt the Sgo1-cohesin interaction, thereby promoting centromeric cohesion de-protection and timely chromosome segregation at anaphase onset.

P259/B265

Force Measurement and Micromanipulation of Chromosomes in Multiple Systems Using a Newly-constructed Micromanipulator.

O. Meng, R. Nance, J. Szybist, J. Scott, M. Diehl, A. Cheville, **L. Paliulis**; Bucknell University, Lewisburg, PA.

Correct positioning of chromosomes during cell division (mitosis and meiosis) is essential for correct distribution of chromosomes into daughter cells. Failures in positioning and distribution of chromosomes can have catastrophic consequences for the cell and the organism the cell inhabits. Positioning of chromosomes relies on balancing forces experienced by chromosomes through their attachments to the spindle. Understanding what forces are felt by chromosomes attached to the spindle requires that the forces be measured. Mitotic forces have only been measured in a small set of organisms and types of division. We have designed and built a new micromanipulator that has adjustable sensitivity and has ideal features for measuring forces on chromosomes. We used the micromanipulator to move chromosomes in cells in mitosis, meiosis I, and meiosis II. We also used the micromanipulator to stall a chromosome's anaphase movements and have gotten preliminary stall force measurements in a number of systems. Our initial measurements were consistent with those Bruce Nicklas obtained using a similar system (on the order of piconewtons). In the future, we plan to use this micromanipulator to measure forces on different types of chromosomes (e.g. holocentric, monocentric, distance-segregating, oscillating, etc.) in mitosis, meiosis I, and meiosis II.

P260/B266

Actin Destabilization Selectively Causes One Spindle Pole to Rotate and Those Kinetochores to Detach and Migrate to the Opposite Pole in *Mesostoma Ehrenbergii* Spermatocytes.

D. Patel, E. Dommar, E. Fegaras, A. Forer; York University, North York, ON, CANADA.

Chromosome movement and segregation in meiotic cell division differs from the norm in *Mesostoma ehrenbergii* spermatocytes. The atypical features of their division include a pre-anaphase cleavage furrow and a prolonged prometaphase in which bivalents persistently oscillate between the two poles before entering anaphase. Additionally, these cells are speculated to divide via non-random segregation, a process where sets of chromosomes segregate to a specific pole (Ferraro-Gideon et al 2014). Due to these characteristics, the *Mesostoma* provides a useful model to study chromosome movement and non-random segregation. It is primarily theorized that spindle microtubules drive chromosome movement. However, previous results with *Mesostoma* have shown chromosomes continue to move when microtubules are depolymerized using nocodazole (NOC) (Fegaras and Forer 2018). These results also showed all three bivalents selectively detach and move to one pole, adding evidence to the theory *Mesostoma* spermatocytes divide non-randomly. To determine what proteins may be responsible for chromosome movement in the absence of microtubules and why the movement is one-sided, we targeted actin using the actin-stabilizing drug, Jasplakinolide (Jasp). We targeted actin because it has been found in the meiotic spindle in various other cell types, and is implicated in *Mesostoma* bivalent oscillations (Silverio 2017). We recorded live cells to monitor the effects on chromosome movement. Jasp had no effect on the speed of bivalent oscillations, instead, it caused kinetochores at only one pole to rotate at different angles along the cell membrane. Interestingly, those kinetochores at the rotating pole consistently moved to the opposite pole, in a similar fashion to NOC treated cells. Unlike NOC, the precocious furrow moved towards the pole with more chromosomes, as opposed to fewer chromosomes. We do not yet know why the furrow responds in this manner. In summary, our preliminary Jasp results implicate actin's involvement in chromosome movement, and due to the one-sided movement, our results further suggest these cells divide via non-random segregation. Future experiments will be done using Jasp and NOC in a double drug experiment, to test whether the same pole that changes orientation in Jasp is also the same pole that detaches during NOC treatment. If it is the same pole, this will again implicate actin is involved in chromosome movement and whether there is specificity in pole selection.

P261/B267

An an alysis of Dicentric Chromosome Breakage in Yeast.

S. K. Long, P. Cusick, D. Cook, C. Lawrimore, K. Bloom; University of North Carolina, Chapel Hill, NC.

An an alysis of Dicentric Chromosome Breakage in Yeast Centromeres mediate kinetochore and microtubule attachment to sister chromatids and are essential for faithful chromosome segregation. Multiple active centromeres, however, leads to genome instability. While dicentric chromosomes occur naturally, one of the centromeres is usually silenced. In 1939, Barbara McClintock noted that having 2 activated centromeres on a single chromosome was highly unstable and caused double stranded breaks in DNA. Dicentric cells can repair double stranded breaks via a breakage-fusion-bridge cycle that will result in a monocentric derivative, allowing the cell to undergo normal division without further breakage. Because the centromere and surrounding region (pericentromere) contain vital cell machinery, we hypothesize that the pericentromere represents a unique environment within the cell

that uses different repair mechanisms than those used on the chromosome arm. To test this, we created dicentric yeast strains containing the endogenous centromere (Cen3), and a second, conditionally activated centromere (Galcen) that is activated in the absence of galactose. We inserted Galcen at varying distances from Cen3, adjacent to specific nonessential genes flanking the pericentromere, a region which extends approximately 10 kilobases (Kb) beyond the endogenous centromere. Engineered mutations in the Rad52 repair pathway, as well as direct and indirect Galcen polarities were used to better characterize the repair mechanisms used in the pericentromere, such as single strand annealing, ring-rod repair, and dicentric regeneration.

Micronuclei Resulting from Different Insults, Differently Impact Genomic Stability.

L. A. Sepaniac[1], W. Martin[2], L. G. Reinholdt[2], J. K. Stumpff[1]; [1]University of Vermont, Burlington, VT, [2]The Jackson Laboratory, Bar Harbor, ME.

Micronuclei contain chromosomes excluded from the main nucleus and are often used clinically to evaluate genomic instability. Cells that enter cell division with a micronucleus can incur severe, localized DNA rearrangements to the micronucleated chromosome [1,2]. This catastrophic process, termed chromothripsis, has been identified as an early event in tumorigenesis [2-5]. Further, loss of micronuclear envelope integrity can also lead to genomic instability by exposing the chromosome to damage in the cell's cytoplasm [6-7]. We have made the paradoxical discovery that mice with a mutation in the kinesin motor *Kif18a* form micronuclei as a result of chromosome alignment defects but do not develop tumors. Further, *Kif18a* mutant mice display resistance to induced colorectal tumors [8]. We are using a combination of in *vitro* cell culture experiments and transgenic mouse models to understand why micronuclei do not lead to tumorigenesis in *Kif18a* mutant mice. Specifically, we are evaluating the nuclear envelope integrity and division rate of cells containing micronuclei induced by loss of (1) chromosome alignment, (2) merotelic kinetochore microtubule attachments, and (3) DNA double strand breaks, both in the presence and absence of p53 activity. Our data indicate that the probability of micronuclear envelope rupture differs among micronuclei caused by different cellular insults but that the rate of micronucleated cell division is reduced by p53 regardless of the insult. These data suggest that multiple defects may be necessary for a micronucleus to promote genomic instability and increase the likelihood of cellular transformation. 1. P263/B269

Lysosomal Degradation Ensures Accurate Chromosomal Segregation to Prevent Genomic Instability.

E. Almacellas[1,2], S. Ambrosio[3], A. Tauler[1,2], C. Mauvezin[1]; [1]Metabolism and Cancer Laboratory, ONCOBELL Program, Bellvitge Biomedical Research Institute IDIBELL, Hospitalet de Llobregat, SPAIN, [2]Department of Biochemistry and Physiology, Faculty of Pharmacy, University of Barcelona, Barcelona, SPAIN, [3]Department of Physiological Sciences, Faculty of Medicine and Health Sciences, University of Barcelona, Hospitalet de Llobregat, SPAIN.

Lysosomes, as primary degradative organelles, are the end-point of different converging pathways including macroautophagy. To date, lysosome function has mainly focused on interphase cells, while

their role during mitosis remains controversial. Mitosis dictates the faithfultransmission of genetic material among generations, and perturbations of mitotic division lead to chromosomal instability, a hallmark of cancer. Heretofore, correct mitotic progression relies on the orchestrated degradation of mitotic factors, which was mainly attributed to ubiquitin-triggered proteasome-dependent degradation. Here, we show that mitotic transition does not only rely on proteasome-dependent degradation, as impairment of lysosomes increases mitotic timing andleads to mitotic errors, thus promoting chromosomal instability. Furthermore, we identified several putative lysosomal targets in mitotic cells. Among them, WAPL, a cohesin regulatory protein, emerged as a novel p62-interacting protein for targeted lysosomal degradation. Finally, we characterized an atypical nuclear phenotype, the toroidal nucleus, as a novel biomarker for genotoxic screenings. Our results establish lysosome-dependent degradation as an essential event to prevent genomic instability.

Investigating the Role of Metabolically Linked Cell-Extracellular Matrix Interactions on the Breast Cancer Stem-like Cell Phenotype.

A. A. Shimpi[1], M. L. Tan[1], L. M. Roberts[1], Z. Cheng[2], O. Reizes[3], M. J. Paszek[2,4], C. Fischbach[1,4]; [1]Meinig School of Biomedical Engineering, Cornell University, Ithaca, NY, [2]Smith School of Chemical and Biomolecular Engineering Cornell University, Ithaca, NY, [3]Department of Cellular and Molecular Medicine, Lerner Research Institute, Cleveland, OH, [4]Kavli Institute at Cornell for Nanoscale Science, Cornell University, Ithaca, NY.

A subpopulation of breast cancer cells with stem-like characteristics (CSCs) contributes to worse clinical prognosis and is characterized by metabolic plasticity. However, the mechanisms leading to the development of CSCs and the role of metabolism in this process remain to be elucidated. Altered cell-extracellular matrix (ECM) interactions have been shown independently to modulate stemness and metabolic reprogramming, but whether there exists a functional link between cancer cell stemness, metabolism, and adhesion is unclear. Here, we hypothesized that changes in tumor cell metabolism promote a CSC phenotype by altering cell-substrate interactions. To address this hypothesis, we employed an established NANOG-MDA-MB231 reporter cell line (MDA:NANOG) that allows detection of CSCs via increased GFP expression. Seahorse metabolic flux analysis of sorted MDA:NANOG cells revealed that more stem-like, GFP-high cells exhibited increased oxygen consumption and glycolysis relative to more differentiated GFP-null cells. Accordingly, increased glucose concentration increased GFP, while blocking glycolysis with 2-deoxyglucose decreased stem cell marker expression. Image analysis further revealed a negative correlation between GFP expression and cell spreading whereas phosphorylated focal adhesion kinase (pFAK) positively correlated with GFP expression. These results suggested that CSCs exhibit metabolism-dependent differences in mechanotransduction relative to their more differentiated counterparts. Indeed, traction force microscopy elucidated that stem-like MDA:NANOG display a ~2.5-fold decrease in total cellular traction force compared to more differentiated cells. As the glycocalyx is critically involved in cell adhesion, regulates phosphorylation of FAK, is subject to metabolic regulation, and contains hyaluronic acid (HA), a ligand for the CSC marker CD44, we next tested whether the observed stemness-dependent differences in adhesion may be due to altered cell-surface associated HA. Indeed, overexpression of HA synthase 3 in MCF10A not only

increased glycolysis, but also decreased cell spreading, while increasing the activity of the stem cell marker aldehyde dehydrogenase. Correspondingly, higher levels of cell-surface-associated HA correlated with increased GFP expression in MDA:NANOG reporter cells, whereas inhibition of HA synthesis with 4-methylumbelliferone increased cell spreading but decreased GFP expression. Together, our data suggest that the increased glycolytic capacity of breast CSCs increases glycocalyx-HA levels to alter cell adhesive properties, which may help explain why increased HA content in tumors correlates with poor clinical outcome in patients.

Control of the Homeostasis of Endolysosomes by the Paracaspase Malt1 Regulates Glioma Cell Survival.

K. Jacobs[1], **J. GAVARD**[1,2,3]; [1]INSERM, Nantes, FRANCE, [2]CNRS, Nantes, FRANCE, [3]Universite Nantes, Nantes, FRANCE.

Glioblastoma is one of the most lethal forms of adult cancer with a median survival of around 15 months. A potential treatment strategy involves targeting glioblastoma stem-like cells (GSC), which constitute a cell autonomous reservoir of aberrant cells able to initiate, maintain, and repopulate the tumor mass. Here, we report that the expression of the paracaspase mucosa-associated lymphoid tissue l (MALT1), a protease previously linked to antigen receptor-mediated NF-κB activation and B-cell lymphoma survival, inversely correlates with patient probability of survival. The knockdown of *MALT1* largely impaired the expansion of patient-derived stem-like cells in *vitro*, and this could be recapitulated with pharmacological inhibitors, in *vitro* and in *vivo*. Blocking MALT1 protease activity increases the endo-lysosome abundance, impaired autophagic flux, and culminates in lysosomal-mediated death, concomitantly with mTOR inactivation and dispersion from lysosomes. These findings place MALT1 as a new druggable target involved in glioblastoma and unveil ways to modulate the homeostasis of endo-lysosomes.

Characterizing Stem Cell Marker Properties in Non-malignant and Malignant Breast Cancer Cells Under Three-dimensional Conditions.

L. Hernandez, C. Ezeh, M. Bissell, M. Mboge; Lawrence Berkeley National Laboratory, Berkeley, CA.

Despite the advances in breast cancer detection and treatment, it still remains the second leading cause of cancer-related deaths among women. Therefore, developing more effective therapeutics for the treatment of this deadly disease is imperative. The mechanisms that lead to aberrant cell proliferation, dedifferentiation, and eventually oncogenesis, however, remain largely unknown. Previous studies in the Bissell lab have shown that the cellular microenvironment plays a significant role in mammary gland differentiation and function, particularly, the extracellular matrix (ECM). Similarly, cancer stem cells (CSC) have been shown to contribute to tumorigenesis, disease progression and therapeutic resistance, in a process that is potentially regulated by the ECM. More specifically, CSC markers (CD44+/CD24-/low and CD49f+) initiated tumorigenesis when expressed on the surface of breast cancer cells. However, the ECM exerted effects on these markers were not taken into account since most of the initial studies were performed under 2D conditions. Therefore, our goal was to characterize the expression patterns of these CSC markers in the HMT3522 breast series of cell lines under more physiological 3D conditions. We hypothesized that malignant HMT3522 breast cancer cells, and not their non-malignant

counterparts, will exhibit enhanced stem-like properties similar to those associated with tumor formation in mice. To test this, we first compared CD24, CD44 and CD49f expression across different cancer subtypes using deposited TCGA patient data. Then, we correlated these markers' expression in breast cancer patients to survival. Our results showed increasingly higher alteration frequencies in CD24, CD49f, and CD44 among all cancer subtypes with gene amplification being the most common type of alteration. RNA expression of these markers was also determined in breast cancer cell lines, under 2D and 3D conditions, using microarray and qPCR. These findings were then validated using western blot analysis. Significant differences in CD24, CD44, and CD49f expression were observed in malignant when compared to non-malignant cells and those treated with growth blocking inhibitors (GBIs), but only under 3D conditions. Phase-contrast microscopy and immunofluorescence imaging were then used to determine the phenotypic differences between these cells, under the same conditions. Treating malignant cells, cultured in 3D environments, with GBIs induced the formation of structures that resemble normal mammary glands that exhibited decrease stem cell properties. Together, these findings validate the expression of CSC related markers in our 3D model. With this information, we can now begin to elucidate the mechanisms that regulate CSC growth and therapeutic resistance.

Cancer Stem Cells Model as the Origin of Tumor-associated Macrophages in Tumor Microenvironment.

A. Osman[1], M. Oze[2], S. M. Afify[3], G. Hassan[2], X. Fu[4], H. M. Nawara[2], A. Seno[2], I. Winer[5], **M. Seno**[2]; [1]kafr Elkheish univerisity, Kafr elsheikh, EGYPT, [2]Okayama University, Okayama, JAPAN, [3]Menoufia univerisity, Shebin Elkom, EGYPT, [4]Tianjin univerisity, Tianjin, CHINA, [5]Wayne State University, Detroit, Michigan, MI.

Abstract: Aim of the study: Tumor-associated macrophages (TAMs) are the most prominent immune cell in the stromal compartment of the tumor microenvironment of solid tumors. Their presence associates with worse prognosis in several cancers. The origins of macrophages in many cancers is still obscured. The present study displayed histological and immunohistochemical analyses of a malignant tumor model developed from cancer stem cells (CSCs) converted from human induced pluripotent stem cells (hiPSCs) in cancer microenvironment prepared by the conditioned medium (CM) of cancer cell line. Especially we focused on the localization and the origin of TAMs, as the furthermost important immune cells and vital source of iron in tumor microenvironment (TME). To the best of our knowledge this may be the first study to suggest the potential differentiation of CSCs to TAMs. **Material and methods:** CSCs were established by culturing hiPSCs in the CM prepared from human pancreatic carcinoma cell line PK8 cells. The markers of stemness and CSCs were evaluated by RT-qPCR. Then CSCs were transplanted and formed primary tumors in immunocompromised mice. The primary culture was serially transplanted again to obtain the secondary tumors. Tumor tissues were subjected to histological, histochemical, immunohistochemical, immunofluorescence, morphometric and statistical studies. **Results:** hiPSCs were converted into CSCs in the presence of CM from PK8 cells. The primary tumors were teratoma while the secondary tumors displayed histopathological features of malignancy. Cells derived from both tumors maintained the expression of endogenous stemness markers, such as Nanog, Oct3/4, Sox2 and c-myc and pancreatic CSCs markers, CD44 and CD133. Tumor sections showed high expression to Ki67, CK19, PTF1A and Sox2 immunohistochemical positive cells. Simultaneously, high immunoreactivity to both anti-human and anti-mouse CD68 antibodies were detected revealing that the tumor tissue derived from CSCs was enriched by macrophages originated from both human and mouse cells. Histological and histochemical examination of tumor tissue showed hemosiderin iron deposits inside several

macrophages. **Conclusions:** the model of CSCs converted from hiPSCs highlighted the importance of the localization and the origin of TAMs as prognostic markers of malignancy. TAMs and tissue-resident macrophages can be regarded as the main link of iron homeostasis in TME. Our study model provides a useful new tool for TAMs research. Further studies of CSCs and TME will provide novel views of cancer development and the ideas of cancer therapies targeting CSCs and TME. **Keywords:** TAMs, TME, Cancer stem cells, hiPSCs, malignant tumor, CD68, hemosiderin iron.

Investigating the Effect of Cannabidiol on Cancer Cells.

M. K. Olmos; Whittier College, Whittier, CA.

Martin Olmos Whittier College Investigating the effect of Cannabidiol on Cancer Cells Cannabis, although commonly associated with its use as a psychoactive drug, also has been shown to alleviate pain and disease symptoms. In particular, Cannabidiol (CBD), a constitute of Cannabis, has demonstrated numerous benefits such as acting as an anti-inflammatory, anticonvulsant, and antioxidant. Studies exploring the benefits of CBD in cancer have shown its ability to trigger the induction of ER stress and inhibition of AKT and mTOR signaling in breast cancer cells, and the upregulation of Beclin 1 triggering apoptosis in melanoma. Taken together these studies suggest that CBD's cytotoxic and anti-proliferative properties may be suitable as a treatment for cancer, and our previous studies demonstrated that CBD exposure as low as 5 ug was effective in statistically decreasing viability in four cancer cell lines, two tumor forming cell lines (LNCaP prostate cancer and MCF-7breast cancer), and two non-tumor forming cancers (Jurkat T-cell leukemia and CML myeloma). Therefore, this current study aimed to explored if lower exposures of CBD could also induce death, and also sought to determine the cellular pathway through which the cells were dying. Using viability and biochemical reporter assays, our findings show the CBD was successful in statistically reducing viability at even low concentrations (1 ug, 2 ug, 4 ug, and 6ug) when exposed to CBD for as little as 24 hours. Using a real time apoptosis/necrosis assay, we also found that 5 ug of CBD exposure induced apoptosis in the MCF-7 cells, but mainly necrosis in the others, LNCaP, Jurkat, and CML cells. The results of these assays were also supported through RT-PCR analysis demonstrating an increase in gene expression of BAX, BCL-2 and BNIP3 and RIP3 respectively. Taken together, these findings lend to the increasing evidence of CBD as a potential viable, alternative, and less harmful treatment option against both adherent and non-adherent cancers.

Histone Demethylase Jmjd2d Promotes Stemness of Liver Cancer Stem Cells through Wnt and Notch Signaling Pathway.

Y. Deng, M. Li, P. Mo, W. Li, C. Yu; Xiamen University, Xiamen, CHINA.

Liver cancer is a highly malignant cancer containing cancer stem cells (CSCs) which contribute to high rate of heterogeneity, metastasis, therapeutic resistance and tumor recurrence resulting in poor outcome and limited therapeutic options. JMJD2D is a Histone Demethylase expressed in some solid tumors, including HCC. However, the molecular mechanisms of JMJD2D in liver CSCs remain unclear. Here, we found that JMJD2D is overexpressed in human liver cancer tissues (52%) and liver cancer stem cells (LCSCs) and indicates poor prognosis. Depletion of JMJD2D markedly inhibited LCSC initiation and progression in *vitro and in vivo*. Furthermore, JMJD2D depletion inhibited Circulating tumor cells (CTCS) and lung metastasis of LCSCs. Mechanistically, JMJD2D promotes Wnt target gene Epcam and Notch

target gene Sox9 expression through interacting with β-catenin/TCF4 and NICD to reduce H3K9me3 levels at the promoter respectively. Finally, the JMJD2D inhibitor 5-c-8HQ can attenuate LCSC stemness in *vitro and in vivo*. Collectively, our findings suggesting that JMJD2D is essential for the LCSCs maintenance of self-renewal and JMJD2D could be a possible therapeutic target against LCSCs.

Lineage Tracing Nucleotide Polymorphisms Via Whole Genome Sequencing in Normal, Premalignant, and Malignant Mammary Populations.

K. S. Meza, C. A. Boulanger, G. H. Smith; National Cancer Institute, Bethesda, MD.

Understanding the development of the normal mammary gland and the role of genetic variations in transforming mammary epithelium towards malignancy is key to providing insight for breast carcinogenesis. In our experimental model, normal, premalignant, and malignant tissues may be derived from the same original cell. These experiments were conducted using the Czech II mouse model to take advantage of their lack of endogenous mouse mammary tumor virus (MMTV). Thus, it was possible to track somatic clonality through viral DNA insertions in the nuclear cellular DNA. These observations have been confirmed through Southern Blot analysis and recently verified through whole genome sequencing. In the present study, we employ whole genome sequencing analysis in an attempt to determine whether genomic polymorphisms define the differences between the premalignant and "normal" outgrowth clones and the mammary tumors that stochastically develop in these cellular populations. We hypothesize that mammary populations may conserve genomic nucleotide polymorphisms in oncogenic progression via selection of clonal progeny arising from the originally infected cell. Genomic DNA (gDNA) was therefore isolated from normal, premalignant, and malignant clonal popuations to determine by whole genome sequence (WGS) the presence of nucleotide polymorphisms and their frequency during oncogenic progression. Our preliminary results were directed mainly toward genomic inheritance of nucleotide polymorphisms in mammary tumors derived from a single premalignant lesion to uncover possible genetic changes associated with oncogenic progression from premalignancy to tumorigenesis. Genes such as Bfsp1, Pappa, Gm11487, EIF3e, Dock4, Pdzm4, and Spear1 were identified as harboring nucleotide polymorphisms among multiple pairs of tumors and metastases but not detected in the normal lactating CzechII mammary gland or the original hyperplasia. Studies are currently underway to determine the impact and consequences of these polymorphisms in tumor progression. Our findings may provide insight into pathways underlying tumorigenesis and lead to development of improved molecular anti-cancer treatment strategies.

Metabolic Coordination of Stem Cell Fate Drives Tumor Initiation.

S. Baksh[1], P. Todorova[2], S. Gur-Cohen[1], E. Fuchs[1], L. Finley[2]; [1]The Rockefeller University, New York, NY, [2]Memorial Sloan Kettering Cancer Center, New York, NY.

Tissue stem cells are the cell of origin for many malignancies. Metabolites regulate the balance between self-renewal and differentiation, but whether endogenous metabolic pathways predispose stem cells to transformation in *vivo* remains unknown. Here, we tackle this question in epidermal stem cells (EpdSCs), a cell of origin for squamous cell carcinoma (SCC). Using genetics, cell and molecular approaches, metabolic profiling and dietary interventions, we find that *de novo* serine synthesis promotes epidermal differentiation. We show that oncogenic EpdSCs restrict glucose-derived serine synthesis, and in doing

so, limit production of alpha-ketoglutarate that drives H3K27me3 loss and epidermal differentiation. When extracellular serine is limiting, enforced serine synthesis induces differentiation and stunts SCC growth, whereas blocking serine synthesis or antagonizing alpha-ketoglutarate-driven demethylation facilitates malignant progression in *vivo*. Thus, metabolic reprogramming that limits serine synthesis supports oncogenic self-renewal and renders SCC initiation sensitive to dietary serine manipulation. These results demonstrate that a stem cell's intrinsic metabolic program dictates its capacity to initiate a neoplasm.

P272/B279

The Tetraspanin CD82 Regulates $S1PR_1$ Mediated Hematopoietic Stem and Progenitor Cell Mobilization.

V. Balise, C. Saito-Reis, E. Pascetti, M. Jiminez, J. Gillette; University of New Mexico, Albuquerque, NM.

The mobilization of hematopoietic stem and progenitor cell (HSPCs) from the bone marrow into the blood occurs under normal physiological conditions and can be stimulated in the clinic to enable the isolation of HSPCs used for transplantation therapies. HSPC transplants are critical treatments for hematological diseases, and thus methods to improve HSPC isolation are of significant interest. Recent work from our laboratory identified the tetraspanin CD82 as a novel regulator of HSPC mobilization. Using a global CD82 knock out (CD82KO) mouse model, we measured enhanced mobilization of HSPCs within CD82KO mice following treatment with the mobilizing agent AMD3100. To determine whether enhanced mobilization was due to CD82KO in the HSPCs rather than the bone marrow microenvironment, C57Bl6 and CD82KO HSPCs were transplanted into lethally irradiated BoyJ mice. Once the bone marrow transplant was established, mice were treated with AMD3100 and similar to previous results, CD82KO HSPCs displayed enhanced mobilization. These data indicate that CD82KO in the HSPCs specially promote enhanced mobilization. Next, we went on to assess the mechanism of enhanced mobilization. While we saw no change in CXCR4 expression or activity, flow cytometry analysis indicates that CD82KO HSPCs have increased surface expression of sphingosine 1-phosphate receptor 1($S1PR_1$), a G-coupled protein receptor that elicits downstream cellular activities such as migration, proliferation and cytoskeletal rearrangement. To confirm a role for $S1PR_1$ in the enhanced mobilization phenotype of CD82KO HSPCs, we performed mobilization assays with the addition of two $S1PR_1$ antagonists 4-deoxypyridoxine (DOP) and FTY720. Upon both FTY720 and DOP treatment, the number of mobilized CD82KO HSPC is decreased when compared to AMD3100 treatment with no difference in mobilization detected between WT and CD82KO mice. These data suggest that the enhanced mobilization of CD82KO HSPCs is dependent upon $S1PR_1$. Current studies aim to identify the mechanism by which CD82KO HSPCs have increased expression of $S1PR_1$ by analyzing $S1PR_1$ transcription factors and using Imagestream cytometry to assess $S1PR_1$ internalization. To identify possible clinical applications, we used a neutralizing CD82 antibody (anti-CD82) to see if blocking CD82 could illicit enhanced mobilization. While anti-CD82 alone shows no effect on white blood cell (WBC) or HSPC mobilization, mice treated with anti-CD82 in combination with AMD3100 display increased WBC and HSPC cell mobilization when compared to controls. Together, these data provide evidence that CD82 is an important regulator of HSPC mobilization and suggests exploiting the CD82 scaffold as a therapeutic target to enhance stem cell mobilization treatments.

Establishment of Cancer Stem Cell Model Overexpressing *BAMBI* and *PORCN and* Attenuating *SFRP1*.

A. Seno[1,2], I. WIner[3], X. Meng[2], W. Liu[2], M. Seno[1]; [1]Okayama University, Okayama, JAPAN, [2]Wayne State University, Detroit, MI, [3]Wayne State University/Karmanos Cancer Center, Detroit, MI.

Background: We have previously proposed a method to develop cancer stem cells (CSCs) from induced pluripotent stem cells (iPSCs) through culture with conditioned media (CM) derived from cancer cells. This is an efficient way to obtain CSCs which potentially represent similar CSCs to in *vivo* populations and will allow the study of inducing events, survival and disease progression. We hypothesized that this method could be extended to ovarian cancer (OVCA) lines. Methods: We utilized human iPSCs (NipsB2) and CM from three different OVCA lines (A2780, MDAH2774, and SKOV3) and analyzed the resultant CSCs by qPCR and RNAseq. To determine tumorigenicity, we examined the cells' ability to form spheroids in *vitro and* utilized an axillary xenograft model in NOD.*Cg-Prkdc*^{scid}*Il2rg*^{tm1Wjl}/SzJ (NSG) mice. Results: All of the NipsB2 derived CSCs (NipsB2-CSCs) expressed stem cell (*NANOG* and *ALDH1*) and CSC (*CD44* and *CD133*) markers and developed spheroids in culture and tumors in NSG mice. RNAseq analysis revealed, in all of the derived CSCs, overexpression of BMP activin membrane-bound inhibitor (*BAMBI)*, a pseudoreceptor of TGFβ, and porcupine (*PORCN*), a WNT acylating enzyme, and downregulation of secreted frizzled-related protein 1 (*SFRP1*), a tumor suppressor. Conclusions: Our NipsB2-CSC demonstrate prototypical gene expression changes seen in primary CSCs isolated in *vivo*. Our results suggest that the NipsB2-CSCs are a model which can be studied further for CSC initiation, survival and disease progression.

P274/B281

Correlation between Sox2 Protein Expression and Prognosis of Lung Cancer Patients.

S. Bae, K. Hong, H. Jang; National Cancer Center, Goyang-si, KOREA, REPUBLIC OF.

The pluripotency-associated transcription factor SOX2 (sex determining region Y-box 2) has been known as a master factor regulating stemness, and several reports suggested that SOX2 played a crucial role in the maintenance of lung cancer stemness. However, there have been discrepancies in the correlation between SOX2 protein expression and patient prognosis, especially in non-small cell lung cancer (NSCLC) adenocarcinoma (LUAD). To clearly understand the relationship between SOX2 and NSCLC, we collected a total of 545 NSCLC patient's samples (287 of LUAD, 243 of lung squamous cell carcinoma (LUSC), and 15 of others) and its clinicopathological information, and analyzed the correlation of the expression levels of SOX2 and the prognosis of NSCLC. As a result, we could find that the expression level of SOX2 is not associated with the prognosis after surgery in NSCLC patients. To further demonstrate our results, we modulated SOX2 protein level by using doxycycline-inducible small hairpin RNA (shRNA)-mediated knockdown and CRISPR/Cas9-mediated knockout systems in two LUAD cell lines. Knockdown of SOX2 by shRNA significantly affected LUAD cell proliferation and tumor sphere formation, but this phenotype was not rescued by the restoration of SOX2. Knockout of SOX2 by the CRISPR/Cas9-system did not result in significant differences in cell proliferation, colony forming assay, tumor sphere formation, and chemoresistance. Overall, this study suggested that SOX2 protein expression is not correlated with lung cancer patient prognosis and care should be taken to generalize SOX2 as a stemness maintenance factor in various cancers.

P275/B282

Comparison of Label Free Imaging Approaches and Destructive in *Vitro* Cell Based Assays for the Assessment of Growth and Viability of Primary Patient-derived Organoid Cancer Models.

H. Desai; American Type Culture Collection, Gaithersburg, MD.

One major challenge in cancer biology is the lack of physiologically relevant models that have long term expansion potential in *vitro*, but still maintain the heterogeneity of the patient tumor. Recent advancements in *in vitro* 3D culture systems such as primary patient-derived organoids can meet this need by providing novel cancer models that better mimic the microenvironment of the originating tumor and exhibit a stable phenotype. A key feature of organoid culture involves embedding cells within a non-defined extracellular matrix that permits the cells to grow in three dimensions into large, complex structures with varying morphologies. These features however, can also make routine quantification of culture health and proliferation challenging. Unlike simpler 2D monolayer cell cultures, organoids do not proliferate as single cells which can make cell counting and viability quantification approaches difficult. The extracellular matrix in which organoids are embedded may also require removal which necessitates additional hands-on processing. Additionally, growth in 3D can interfere with simple visual assessment via brightfield or phase contrast imaging. Here we applied several common approaches for quantification of cell culture health and proliferation to primary patient- derived cancer organoids from multiple tissues, donors and cancer types. Approaches including commercially available kits to quantify metabolism or ATP, as well as the common trypan blue dye exclusion assay were utilized. The results were compared with label free imaging approaches from multiple instrument platforms, which assess growth based on morphological features in brightfield or phase contrast images over time. Additionally, a small-scale toxicity assay was also performed with various chemotherapy drugs to assess the discrimination ability of the assays. Results varied between models, donors, tissues and cancer types. All methods were able to capture long term changes in organoid proliferation, though all faced unique challenges, typically around sample preparation. Traditional in *vitro* assays designed for 2D monolayer cultures could be impeded by the presence of extracellular matrix and had difficulty in penetrating large, multicellular organoids. This resulted in lower signals or higher backgrounds, unless the samples were pre-processed. Imaging based approaches required significant customization and optimization on a per-model basis. Overall, we found that to accurately assess the growth properties of such complex three-dimensional organoid cultures, significant optimization and validation may be required. Depending on the specific application, either imaging based, or cell-based assay approaches may be suitable.

P276/B283

Regulation of ROR1 by Retinoic Acid Induces Differentiation in Neuroblastoma by Modulation of Retinoic Acid Receptor Elements.

A. Illendula, N. Fultang, B. Peethambaran; University of the Scienecs, Philadelphia, PA.

Neuroblastoma is the most common solid neoplasm during childhood. It originates from primitive cells in the sympathetic nervous system that fail to differentiate and propagate rapidly. A common treatment that has been prescribed for over a decade is retinoid therapy (using all-trans retinoic acid (RA)). Treatment with this differentiating agent has been shown to progress the cells from their stem-cell state to a mature neuronal state gaining classical conditions of a neuron, including the repression of proliferation. However, the molecular mechanism behind the action of RA treatment is largely a mystery. Understanding the mechanisms that contribute to both the cancerous properties and

differentiation of neuroblastoma would lead to the discovery of ideal targets for future differentiation therapies. Genomic mining suggests ROR1 activates synaptophysin, a presynaptic regulator that contributes to the formation of synapses. There is also evidence to suggest ROR1 is overexpressed in neuroblastoma but significantly downregulated in mature differentiated neurons. These two functions informed our hypothesis that retinoic acid may modulate ROR1 leading to differentiation and termination of cancerous properties. Immunoblots show that ROR1 levels initially increase and sharply decrease at 96 hours. This is paired with synaptophysin levels sharply increasing at the same time, providing evidence that differentiation ends at 96 hours. Investigation of the ROR1 pathway confirms the downstream mechanism leading to the phosphorylation of β-catenin. Further feedback into the pathway via the MAPK/ERK pathway is seen correlating to the differentiation timescale. To investigate the action of RAR on the expression of ROR1 and its ligand, Wnt5a, ChIP and qPCR were conducted and showed an increase in RAR binding to both genes as well as a sharp expression correlating to its proteomic expression. This data has shown a viable mechanism of action towards neuronal differentiation, as well as repression of neuroblastoma cancer. RA is able to modulate the expression of ROR1 and its ligand to promote differentiation through the expression of synaptophysin and proliferative factors which leads to maturation of the neurons. This research can be further utilized towards targeted therapies in both neuroblastoma, neuronal stem-cell work, and other neuropathologies.

P277/B284

Mechanisms That Impact the Cell Division Axis and Phenotype for Brca1-mutant Mammary Epithelial Cells.

Z. He, C. A. Maxwell; Department of Pediatrics, University of British Columbia, Vancouver, BC, CANADA.

Background *BRCA1* mutations associate with aberrant mammary progenitor cell numbers and breast cancers that display basal-like features. These features of BRCA1 cancers seeded the concept that BRCA1 exerts proliferative control over normal mammary progenitor cells. In *BRCA1* mutation carriers, progesterone-dependent signaling through RANKL-RANK is a critical mediator of tumor initiation potentially through its promotion of progenitor cell proliferation. We discovered that control of the cell division axis is disturbed by silencing BRCA1 or after one allele was edited to carry a causal *185delAG* mutation. In addition, we observed a propensity for BRCA1-silenced human mammary cells grown as colonies to acquire the features of basal cells. **Underlying hypothesis** BRCA1 mutation disrupts control of the cell division axis in mammary epithelial cells, which cooperates with aberrant RANKL - RANK signaling to produce the altered proliferation and disordered homeostasis observed prior to tumor formation. **Results** When stimulated to divide on an L-pattern, a rounded mitotic cell fixes adhesive structures to the pattern that guide the division axis along the hypotenuse of the shape. We have measured cell division angles in MCF10A parental cells and cells engineered to carry one of 13 distinct BRCA1 variants in one allele in our assay. In BRCA1-mutant cells, however, division angles are oriented only for neutral variants. Cells carrying causal variants (6 of 7) or a VUS do not orient cell division. We observed radiation dose-dependent increases in DNA damage and abnormal cell phenotypes but division angles were not significantly altered. When grown as single cells, MCF10A cells form luminal colonies but BRCA1-silenced cells acquire basal feature. Imaging the colony formation revealed that cell divisions at day 1.5 were not oriented in either treatment. Multi-parameter analysis of individual cells found control-treated cells stayed in proximity with more cell contacts, which correlated with acquisition of oriented cell divisions. To discover pathways, we studied proteomes of BRCA1-silenced

and control-treated colonies. We found that gene ontology terms microtubule and growth regulation, which included regulators of NF-κB signaling, were elevated in BRCA1-silenced colonies. We observed the NF-κB pathway was persistently active in BRCA1-silenced cells. Exposure to RANKL increased the basal-like colonies. TaqMan arrays identified seven gene products elevated in BRCA1- silenced colonies, which we confirmed by IF and immunoblot analysis. **Conclusion** These findings reveal a previously unrecognized consequence of mutant BRCA1 on the cell division axis, post-mitotic integrity and phenotype control in normal human mammary epithelial cells.

Anti-cancer Cell Properties of *Prunus Africana*Bark Extracts in Mcf-7 Cells Is Cd44 Expression Dependent.

A. Janik; Delaware State University, Dover, DE.

Prunus africana is a medicinal evergreen tree native to Cameroon and Kenya. Extracts from this tree have been shown to have antimicrobial activity. This activity was dependent on the different part of the tree used to generate the extracts (i.e., leaves, root or bark) as well as the solvents used to prepare them (i.e., acetone, ethanol or methanol). Based on these differential antimicrobial properties, we hypothesize that it is likely that differential anti-cancer cell activities will be found in the different extracts. To test this hypothesis we treated two stably transfected MCF-7-derived breast cancer cell lines; MCF-7/PLXIN (plasmid only control, CD44 negative) and MCF-7/CD44 (pLXIN plasmid expressing CD44 standard, CD44 positive) with Prunus africana bark extracts extracted with aqueous acetone, ethanol or methanol (80% v/v). These extracts were constituted in the same solvents used to prepare the extracts and 10,000 cells per well in 96 well plates were treated in triplicates for 24 h. MTS assays showed higher levels of cell toxicity with ethanol-based and methanol-based extracts compared to acetone-based extracts. This cell toxicity was associated with the expression of CD44 since MCF-7/CD44 cells were more sensitive than MCF-7/PLXIN cells to the extracts. This differential sensitivity indicates that the aqueous ethanol- or methanol bark extracts are targeting the more aggressive CD44-expressing MCF-7-derived cell line.

P279/B286

CHMP6 Negatively Impacts CD147 Levels.

D. Maass, H. McGunnigle, A. R. Lowe, **J. Castorino**; Hampshire College, Amherst, MA.

CD147 (Emmprin, Basigin, BSG) is a single-pass transmembrane glycoprotein that contains two immunoglobulin (Ig)-like domains in the extracellular region. CD147 overexpression has been directly implicated in tumor growth and metastasis. In order for CD147 protein to leave the endoplasmic reticulum and function at the cell surface, it must interact with other proteins. According to the BioGRID, there are currently 203 proteins that potentially interact with CD147, although most of these interactions have no associated functional implications. In order to help explain CD147 overexpression in cancer, we wanted to find new interactants that may impact CD147 levels. We attempted to find relationships between CD147 and various biological processes using a bioinformatics screen. One interesting set of complexes that appeared was the endosomal sorting complex required for transport III (ESCRT-III) machinery. We explored whether a central participant of ESCRT-III, charged multi-vesicular

protein 6 (CHMP6, VPS20), impacts CD147 expression. By western blot, we show that CD147 protein levels are significantly higher in metastatic colorectal cancer HCT116 cells compared to less aggressive HT29 cells. By quantitative RT-PCR, we show that CHMP6 mRNA levels are lower in HCT116 cells compared to HT29 cells. In order to test this inverse relationship between CHMP6 and CD147 levels, we overexpressed CHMP6 in HCT116 cells. By western blot, we observed decreases in both core-glycosylated and fully-glycosylated CD147 levels compared to empty vector controls. By performing fluorescent microscopy on HCT116 cells co-transfected with CD147-GFP and CHMP6-mCherry, we observed partial co-localization of these two proteins. Together, our data indicate that higher levels of CHMP6 correlated with lower CD147 levels.

P280/B287

P53-driven Egfr Recycling and Tumoral Aggressiveness Can Be Counteracted by D-propranolol Involving PKA Activity Down-regulation.

J. Barra-Carrasco, 8200000[1], J. Venegas[1], C. Retamal[1], J. Cerda-Infante[2], L. Sandoval[1], M. Labarca[1], J. Henriquez[2], C. Metz[1], J. Cancino[1], J. Roa[2], S. Miserey-Lenkei[3], V. Montecinos[2], A. González[1]; [1]Universidad San Sebastian, Santiago, CHILE, [2]Pontificia Universidad Católica de Chile, Santiago, CHILE, [3]Institut Curie, Paris, FRANCE.

EGFR regulates processes of proliferation and migration/invasion and is frequently altered in cancer, offering a variety of opportunities as anti-tumoral target. Endocytic trafficking, as the main regulator of EGFR function, can be exploited to counteract EGFR-dependent malignant traits. EGFR recycling with implication in proliferation and invasive migration has been found enhanced in tumoral cells that express gain-of-function (GOF) missense mutations of *TP53*, the most frequent mutations in this otherwise tumor suppressive gene. We are currently studying a PKA pathway that regulates EGFR endocytic trafficking and can be used to arrest both ligand-activated and empty-inactivated EGFR at recycling endosomes. PKA inhibition induces ligand independent EGFR endocytosis and decreases its recycling. As a potential anti-tumoral drug that avoids the toxicity of direct PKA inhibitors we have described the use of D-Propranolol (D-Prop) as an inductor of phosphatidic acid (PA) levels by inhibiting PA hydrolysis. PA activates type 4 phosphodiesterase (PDE4) and subsequently decreases PKA activity mimicking the effects of PKA inhibitors such as H89 on EGFR trafficking. Here we identify proteins involved in PKA-mediated EGFR internalization and assess D-prop effects on cancer cells expressing p53 missense mutations. H89 and D-Prop reduced PKA phosphorylation of PAK4 and GEF-H1 (cytoskeletal regulators) and Rab-Coupling-Protein RCP (Rab11 effector involved in recycling). PAK4 and GEF-H1 silencing inhibited EGFR recycling. H89, D-prop and PKA phosphorylation site mutation S435A of RCP enhanced EGFR interaction with RCP, α5β1 integrin and Rab11, colocalizing at perinuclear recycling endosomes, where the EGFR become arrested with functional consequences upon cell proliferation and invasive migration. In tumoral cells expressing GOF p53 missense mutations, D-Prop inhibited proliferation and invasion, counteracted tumoral growth and increased survival of immunosuppressive mice xenografted with G415-$p53^{R282W}$ gallbladder cancer cells. These results involve PAK4, GEFH1 and RCP as PKA substrates that regulate EGFR endocytic trafficking and demonstrate the anti-tumoral potential of D-prop used to counteract p53-driven EGFR recycling and cancer aggressiveness. (Financed by FONDECYT#1181907 and CONICYT Basal grants AFB170005 and AFB170004)

P281/B288

New Causal Drivers of Estrogen Signaling Revealed by Dense Time Series of Nascent Rna Transcription.

J. Azofeifa, J. Basken; Arpeggio Bio, Boulder, CO.

Mechanistic understanding of Estrogen Receptor (ER) signaling will lead to new therapeutic targets for ER positive breast cancer. To this end, we performed nascent RNA sequencing following estradiol (E2) treatment in MCF7 breast cancer cells every 15 minutes for 6 hours. To date, our study represents the densest time series of estrogen signaling ever reported. We noted three transcriptional waves following E2 treatment: peaks at 30 minutes, 2.5 hours and 5 hours respectively. We noted that the early response was enriched for canonical ER signaling, however mid and late response were enriched for metabolic processes. Because our study was statistically powered with 24 time points, we could use delay-coordinate embedding to look for causal gene interactions. We implicated NME2 as the causal driver of the 5-hour transcriptional wave. Indeed, NME2 and Estrogen Receptor (ER) have been shown to co-localize where NME2 blocks ER effect. Our study represents a new methodology for target discovery in hormone driven cancers.

Phosphofructokinases Axis Controls Glucose-dependent MTORC1 Activation Driven by E2f1.

E. Almacellas[1,2], J. Pelletier[1], A. Manzano[3], A. Gentilella[1,2], S. Ambrosio[3], C. Mauvezin[1], A. Tauler[1,2]; [1]Laboratory of Cancer Metabolism, Molecular Mechanisms and Experimental Therapy in Oncology Program (Oncobell), Institut d'Investigació Biomèdica de Bellvitge (IDIBELL), Hospitalet del Llobregat, SPAIN, [2]Department of Biochemistry and Physiology, School of Pharmacy, University of Barcelona, Barcelona, SPAIN, [3]Biochemistry Unit, Physiological Sciences Department, Faculty of Medicine and Health Science, University of Barcelona (IDIBELL), Hospitalet del Llobregat, SPAIN.

Cancer cells rely on mTORC1 activity to coordinate mitogenic signaling with nutrients availability for growth. Based on the metabolic function of E2F1, we hypothesize that glucose catabolism driven by E2F1 could participate on mTORC1 activation. Here, we demonstrate that glucose potentiates E2F1-induced mTORC1 activation by promoting mTORC1 translocation to lysosomes, a process that occurs independently of AMPK activation. We showed that E2F1 regulates glucose metabolism by increasing aerobic glycolysis and identified the PFKFB3 regulatory enzyme as an E2F1-regulated gene important for mTORC1 activation. Furthermore, PFKFB3 and PFK1 were found associated to lysosomes and we demonstrated that modulation of PFKFB3 activity, either by substrate accessibility or expression, regulates the translocation of mTORC1 to lysosomes by direct interaction with Rag B and subsequent mTORC1 activity. Our results support a model where a glycolytic metabolon containing phosphofructokinases transiently interacts with the lysosome acting as a sensor platform for glucose catabolism towards mTORC1 activity.

P283/B290

P53 Activation Attenuates ISR Induced by ETC Inhibition in HCT116 Carcinoma Cell Line.

A. A. Dalina[1], G. G. Safronov[2], I. E. Kovaleva[3], A. G. Evstafieva[3,2]; [1]Engelhardt Institute of Molecular Biology, Russian Academy of Sciences, Moscow, RUSSIAN FEDERATION, [2]Faculty of Bioengineering and Bioinformatics, Lomonosov State University, Moscow, RUSSIAN FEDERATION, [3]Belozersky Institute of Physico-Chemical Biology, Lomonosov State University, Moscow, RUSSIAN FEDERATION.

The Integrated Stress Response and p53-mediated signaling are two major programs of the cellular stress response. The Integrated Stress Response (ISR) is an adaptive signaling pathway activated by numerous metabolic stresses such as nutrient deprivation, hypoxia, or proteotoxic stress. Transcription factor ATF4 is a key regulator of ISR. The p53 tumor suppressor integrates a wide range of different stimuli and triggers antiproliferative stress responses. The interaction of these two major anti-stress networks has not been well studied. Previously we have shown that p53 activation upon a sustained inhibition of ETC complex III by myxothiazol abolishes the earlier activation of ATF4 and its target genes. The aim of this study is to find out whether p53-dependent repression of the ATF4-mediated transcription is limited to this particular stimulus or represents a common event and to develop approaches to explore the underlying mechanisms. ATF4 was induced by different ISR activators, and levels of mRNAs of ATF4 and its targets (SLC7A11, CHOP, ASNS, TRIB3) in HCT116 cells upon treatment with various p53 inducing agents (doxorubicin, 5-fluorouracil, and nutlin-3a) were assessed using RT-qPCR. We found that treatment with p53 inducing agents caused a decrease in mRNA levels of ATF4 and its targets when ATF4 was not activated or when it was activated by ETC inhibitors piericidin a and myxothiazol, while p21 mRNA level was significantly elevated. Doxorubicin and nutlin-3a also suppressed ATF4-mediated transcription activation during endoplasmic reticulum stress induced by tunicamycin. Thus, we showed that p53-dependent repression of an ATF4-mediated transcription appears to be a common event that follows the induction of endogenous p53 by various stimuli both under normal conditions and upon Integrated Stress Response activation. To confirm the role of p53 in the suppression of ATF4-mediated transcription, we performed the same experiments using HCT116 p53-/- cells. Repression of ATF4-mediated transcription activation upon treatment with 5-FU and nutlin-3a was significantly prevented in the absence of p53. We tested a possible role of p21, which is a known p53 target, in p53-dependent repression of ATF4-mediated transcription in HCT116 p21-/- cells and observed a similar effect. Taken together, these results suggest an important role of the p53/p21-dependent signaling pathway activation in the attenuation of ISR. This work was supported by RFBR grant 18-04-00991 to I.K.

P284/B291

Sur8 Stabilization by PKCa/ddegradation Plays a Role in Transformation, Migration, and Invasion of CRC Cells.

D. KWAK; Yonsei University, Seoul, KOREA, REPUBLIC OF.

Scaffold proteins of the mitogen activated protein kinase (MAPK) pathway recruit protein kinase cascades to confer context-specificity to cellular signaling. However, regulatory mechanisms of scaffold proteins are poorly understood. Sur8, a scaffold protein in the Ras-MAPK pathway, is known to be involved in cell transformation and migration, and is increased in human colorectal cancer (CRC) patient tissue. Here we determine that regulation of Sur8 stability mediates transformation and migration of CRC cells. Fibroblast growth factor 2 (FGF2) is identified as an external regulator that stabilizes Sur8. Protein kinase C-alpha and -delta (PKCα/δ) are also identified as specific mediators of FGF2 regulation of Sur8 stability. PKCα/δ phosphorylate Sur8 at Thr-71 and Ser-297, respectively. This phosphorylation is essential for polyubiquitin-dependent degradation of Sur8. Sur8 mutations, which mimic phosphorylation by PKCα/δ and destabilized Sur8, suppress the FGF2-induced transformation and migration of CRC cells. Overall, our findings demonstrate for the first time a regulatory mechanism of Sur8 stability involving cellular transformation and migration in CRC.

P285/B292

G-protein Coupled Receptor 64: a Potential Tumor Suppressor in Endometrial Cancer.

J. YOO, H. Yoon; Yonsei University College of Medicine, Seoul, KOREA, REPUBLIC OF.

Endometrial cancer is the most common gynecological cancer. G-protein coupled receptor 64 (GPR64) belongs to a family of adhesion GPCRs and plays an important role for male fertility. However, GPR64 function has not been reported in endometrial cancer. Our objective is to investigate the role of GPR64 in endometrial cancer. We examined the levels of GPR64 in human endometrial cancer tissue by immunohistochemistry analysis. GPR64 levels were significantly lower in 10 of 21 (47.62%) of endometrial carcinoma samples compared to control. To test whether GPR64 has a role of tumor suppressor in endometrial cancer, we used a siRNA loss of function approach in human endometrial adenocarcinoma cell lines. Depletion of *GPR64* by siRNA transfection in Ishikawa and HEC1A cells showed an increase of colony formation ability and cell proliferation. Depletion of *GPR64* also significantly increased the migration and invasion activity of Ishikawa and HEC1A cells. Furthermore, the phosphorylation of AMP-activated protein kinase (AMPK) and expression of *Connexin 43* (*Cx43*), a member of the large family of gap junction proteins, were regulated in *GPR64*-deficient Ishikawa cells. These results suggest that GPR64 play an important role for cell proliferation, migration, and invasion as a tumor suppressor in endometrial cancer.

TGF-β Induced Alternative Splicing of Tak1 and Implication in EMT and Drug Resistance.

J. Shin, V. Tripathi, C. H. Stuelten, Y. E. Zhang; NCI/NIH, Bethesda, MD.

Transforming growth factor-β (TGF-β) is major inducer of epithelial-to-mesenchymal transition (EMT), which associates with cancer cell metastasis and resistance to chemotherapy and targeted drugs, through both transcriptional and non-transcriptional mechanisms. We previously reported that, in cancer cells, heightened mitogenic signaling allows TGF-β-activated Smad3 to interact with poly(RC) binding protein 1 (PCBP1) and together they regulate many alternative splicing events that favors expression of protein isoforms essential for EMT, cytoskeletal rearrangement, and adherens junction signaling. We now extended these observations to TGF-β-activated kinase 1 (TAK1), which plays an essential role in mediating TGF-β activation of JNK, p38 and nuclear factor kappa B (NF-κB). We found that the exclusion of TGF-β-activated kinase 1 (TAK1) variable exon 12 requires another RNA binding protein, Fox-1 homolog 2 (Rbfox2), which binds intronic sequences in front of exon 12 independently of the Smad3–PCBP1 complex. Functionally, exon 12-excluded TAK1ΔE12 and full-length TAK1FL are distinct. The short isoform TAK1ΔE12 is constitutively active and supports TGF-β-induced EMT and nuclear factor kappa B (NF-κB) signaling, whereas the full-length isoform TAK1FL promotes TGF-β-induced apoptosis. These observations offer a harmonious explanation for how a single TAK1 kinase can mediate the opposing responses of cell survival and apoptosis in response to TGF-β. They also reveal a propensity of the alternatively spliced TAK1 isoform TAK1ΔE12 to cause drug resistance due to its activity in supporting EMT and NF-κB survival signaling. These results uncovered a new mechanism for how TGF-β induces opposing responses to cell survival and apoptosis through TAK1. Furthermore, they provided insights for a new strategy to overcome resistance and to increase sensitivity of tumor cells to cancer chemotherapies and targeted drugs.

Asap1 Regulates Differentiation in Myoblasts and PAX-FOXO1 Fusion-negative Rhabdomyosarcoma through the Arf GTPase Pathway.

K. E. Hebron, O. Feehan-Nelson, X. Jian, P. Randazzo, M. Yohe; National Cancer Institute, NIH, Bethesda, MD.

Rhabdomyosarcoma (RMS), the most frequently diagnosed soft tissue sarcoma in children, is caused by a differentiation defect in skeletal muscle precursor cells. Despite aggressive, multimodal therapies, the prognosis for recurrent PAX-FOXO1 fusion-negative RMS (FN-RMS) remains poor. Inducing differentiation in diseases defined by defective differentiation programs has led to curative therapies in cancers such as acute promyelocytic leukemia. A recent study showed that inducing differentiation slowed tumor growth and extended survival in a xenograft model of FN-RMS, identifying differentiation as a promising therapeutic target in FN-RMS. However, genes associated with differentiation are frequently found to be hijacked by tumor cells and repurposed for pro-invasive programs. Therefore, better understanding of differentiation signaling and its relation to invasion could reveal novel therapeutic opportunities for patients with advanced FN-RMS. We hypothesize that ASAP1, an Arf GTPase-activating protein implicated in differentiation in normal cells and invasion in carcinoma, promotes progression by controlling pro-invasive elements of differentiation signaling through focal adhesion assembly. ASAP1, an Arf GTPase-activating protein (Arf GAP), regulates integrin adhesion complexes, critical regulators of biological processes such as proliferation, migration, and differentiation that are commonly dysregulated in cancer. ASAP1 is overexpressed in several cancers and correlates with increased metastasis and poor patient prognosis but has also been shown to promote differentiation. The mechanisms by which ASAP1 affects cancer progression and differentiation and the relationship between these effects are not yet understood. We found that ASAP1 is overexpressed in FN-RMS. ASAP1 overexpression inhibits proliferation in myoblasts, but not in FN-RMS. Knockdown of ASAP1 inhibits differentiation in both myoblast and FN-RMS cell lines, while overexpression enhances differentiation. Moreover, gene set enrichment analysis shows that myoblast differentiation-associated genes fail to become enriched upon knockdown of ASAP1. Finally, knockdown of Arf1 and Arf5, established binding partners of ASAP1, also block differentiation of FN-RMS cell lines, indicating that ASAP1 may regulate differentiation through its interaction with Arf GTPases. These data support our hypothesis that ASAP1 regulates the continuum of differentiation and invasion in FN-RMS. As a continuing test of the hypothesis, future studies will investigate focal adhesion assembly, dynamics, and signaling, which are processes known to be affected by ASAP1, as a mechanism for ASAP1-mediated regulation of myoblast differentiation.

P288/B295

Metabolic Syndrome Complex Protein 1 Is a Potential Role for Tumor Survival Via Mitochondria Dynamics in Hepatocellular Carcinoma.

C. Kim[1,2], Q. Tran[1,2], H. Lee[1,2], G. Kong[1,2], J. Park[1,2]; [1]1Department of Pharmacology, Metabolic Syndrome and Cell Signaling Laboratory, Institute for Cancer Research, College of Medicine, Chungnam National University, Daejeon, KOREA, REPUBLIC OF, [2]2Department of Medical Science, College of Medicine, Chungnam National University, Daejeon, KOREA, REPUBLIC OF.

MSCP1 (Metabolic Syndrome Complex Protein 1) released into cytosol by apoptosis signal. After, MSCP1 inhibits phosphorylation at Ser473 of PKBα. PKB is a key molecular in cell signaling relating to cell

survival and an oncogene which induces cell proliferation, growth and anti-apoptosis. Also, MSCP1 is an thioesterase that functions as hydrolysis thioester bonds on medium-chain, long-chain acyl-CoA. Previous study, MSCP1 intensified phosphorylation of PKB in breast cancer and HNSCC(head and neck squamous cell carcinoma). In our study, depending on the cell type, MSCP1 has been shown to influence tumor survival through the regulation of mitochondria dynamics and lipid metabolism in HNSCC. An d we investigated the effect of MSCP1 on hepatocellular carcinoma, because HCC is the most common tumor worldwide. Cell proliferation and migration was decreased in HepG2 cells and Hep3B cells when MSCP1 was overexpressed. Accordingly, we hypothesize that expression of MSCP1 affects tumor survival by regulating mitochondria dynamics and lipid metabolism in HCC.

Multiple Primary Tumors with Differential Drug Sensitivity.

S. Wilkinson[1], H. Ye[2], N. T. Terrigino[1], N. Carrabba[1], R. Atway[1], S. Y. Trostel[1], J. R. Bright[1], S. T. Hennigan[1], R. T. Lis[3], R. Lake[1], S. Harmon[1], B. Turkbey[1], P. A. Pinto[1], P. L. Choyke[1], F. Karzai[1], D. J. VanderWeele[1], K. Kelly[1], W. L. Dahut[1], A. G. Sowalsky[1]; [1]National Cancer Institute, Bethesda, MD, [2]UCLA, Los an geles, CA, [3]Dana-Farber Cancer Institute, Boston, MA.

Localized prostate cancers are uniquely genetically variable, comprising both spatially separate regions and multiple independently evolving clones within each region. The multifocality of prostate cancer is a well-acknowledged problem for diagnosis, and the differential aggressiveness of potentially independent clones remains largely unknown. Further, appropriate prostate cancer staging using multiparametric MRI (mpMRI) and biopsy tissue can be confounded by sampling error. To date, there has been no understanding of whether this variability influences management decisions for localized prostate tumors. Here, we sought to identify the sensitivity and genomic profile of distinct localized tumors from a single patient following systemic intense neoadjuvant androgen deprivation therapy. A high risk prostate cancer patient was enrolled in a Phase 2 study of neoadjuvant androgen deprivation therapy (ADT) plus enzalutamide. mpMRI was performed at baseline, showing a single semi-contiguous lesion encompassing the right apical-mid peripheral zone also extending into the left distal apical peripheral zone. MR/ultrasound-fusion targeted biopsy was performed before undergoing 6 months of intense neoadjuvant ADT. Biopsies of the left- and right-sided tumors showed differing histologies. A second mpMRI was performed following therapy before radical prostatectomy. Laser capture microdissection was performed to isolate pure populations of tumor cells from the pre-treatment biopsy and post-treatment surgical specimen. Whole exome sequencing was performed on microdissected tissues to identify somatic mutations and copy number alterations, which were further used to assess tumor clonal architecture and genomic/phenotypic evolution of treatment resistant tumor. mpMRI and pathology showed near complete response of one tumor and substantial resistance of the other tumor. Histopathological staining and whole exome data highlighted a divergence in the status of tumor suppressor genes implicated in prostate cancer progression, with the non-responding tumor at baseline exhibiting additional alterations absent from the pre-treatment tumor that responded to therapy. Using point mutations as definitive clonal markers, we found that two clonally-independent tumors exhibited intrinsic heterogeneity at baseline which correlated with response or resistance.

Lectin ZG16p Inhibits Proliferation of Human Colorectal Cancer Cells Via Its Carbohydrate-binding Sites.

K. Kojima-Aikawa, A. Mito; Ochanomizu University, Tokyo, JAPAN.

Zymogen granule protein 16 (ZG16p) is a soluble 16 kDa protein and is highly expressed in human pancreas, liver and intestine. ZG16p has a β-prism fold structure similar to Jacalin-related lectins (JRLs) and binds to mannose via GG and GXXXD loops which are conserved among JRLs. ZG16p also interacts with negative-charged heparin/heparan sulfate via basic amino acids. ZG16p is highly expressed in the human digestive tract and is secreted into the mucus. It has been reported that the expression of ZG16p is downregulated in colorectal tumor tissue compared with normal tissue and low expression of ZG16p is related with shorter survival of colorectal cancer patients. However, the implication of downregulation of ZG16p in colorectal cancer remains unclear. In this study, to elucidate whether or not ZG16p is involved in the anti-cancer mechanism in the intestinal epithelia, the effect of ZG16p on the proliferation of colorectal cancer cells and patient-derived colorectal tumor organoids was investigated.Overexpression of ZG16p in Caco-2 cells decreased cell growth. Recombinant ZG16p markedly inhibited proliferation of Caco-2, LS174T, HCT116, and HCT15 cells. Caco-2 cell growth was not inhibited by two mutated ZG16p proteins, D151A and M5 (K36A, R37A, R53A, R55A, and R79A) lacking mannose- and heparin-binding activities, respectively. Immunofluorescent cell staining revealed that ZG16p-D151A maintained its binding to the Caco-2 cell surface, whereas ZG16p-M5 failed to bind to the cells. These results suggest that ZG16p interacts with the cell surface via basic amino acids substituted in ZG16p-M5 and inhibits Caco-2 cell proliferation via Asp151. In addition, growth of patient-derived colorectal tumor organoids in a three-dimensional intestinal stem cell system was suppressed by ZG16p but not by ZG16p-M5. Taken together, our findings indicate that ZG16p inhibits the growth of colorectal cancer cells via its carbohydrate-binding sites in *vitro* and *ex vivo*. A novel pathway in cancer cell growth regulation through cell surface carbohydrate chains is suggested.

Investigating the WDR5 Interaction Network.

A. Guarnaccia, K. R. Lindsey, B. Zhao, G. Shaw, E. T. Olejniczak, S. W. Fesik, W. Tansey; Vanderbilt University, Nashville, TN.

WDR5 is a cellular multitasker, an essential protein involved with histone modifying complexes, transcriptional regulators, mitotic machinery, and more. Because WDR5 is often overexpressed in cancer, understanding and inhibiting WDR5 has therapeutic potential. Key to the functions of WDR5 are mutually exclusive interactions at two binding sites which integrate WDR5 into different cellular processes. One of these binding sites, the Win site, specifically binds arginine-containing motifs of protein binding partners. Integrity of the Win site is necessary for proper function of WDR5, and when the Win site is blocked WDR5 interactions are impaired and a variety of gene expression changes and cellular defects arise. While several direct binding partners of WDR5 are characterized, the specific interactions disrupted by Win site blockade are not known, and it is clear that the current understanding of the WDR5 interactome is not comprehensive. Our work aims to better understand the WDR5 interaction network and determine how these interactions between WDR5 and other proteins influence cellular functions. Recently we and others have been developing small molecules designed to specifically block the Win site. Small molecule inhibition of WDR5 not only carries therapeutic potential but also

allows specific and acute disabling of WDR5 binding sites, enabling basic biological discovery. Our recent work leverages a potent and highly validated small molecule inhibitor of the Win site to identify binding partners of WDR5. Using this inhibitor we performed a SILAC-based quantitative proteomic screen to identify protein binding partners of WDR5 that rely on the Win site. This approach compared Win-site inhibited WDR5 to uninhibited WDR5 and revealed 20 proteins that are specifically displaced from WDR5 by this small molecule. Interestingly, the majority of these 20 proteins have not before been shown to interact with WDR5. Yet every protein from this list that we analyzed by FLAG coimmunoprecipitation validated as interacting with WDR5 in a Win-site dependent manner. These identified WDR5 binding partners set the groundwork for discovering functions of WDR5 that extend beyond the canonical chromatin-linked functions. To focus our study we have narrowed in on a few of these newly identified WDR5-interacting proteins for further characterization of mechanism of binding and functional analysis. These ongoing studies are expanding our understanding of the cellular functions of WDR5. We are learning that WDR5 is an even more versatile and tightly regulated protein than initially grasped. This knowledge is valuable both for understanding how WDR5 is integrated into so many different cellular processes and for informing the development of WDR5 inhibitors as targeted cancer therapy.

Visualizing Native P53 Structures Using Cryo-electron Microscopy.

M. J. Solares[1], Y. Liang[2], W. J. Dearnaley[1], N. A. Alden[2], A. C. Varano[1], D. F. Kelly[1]; [1]Penn State University, University Park, PA, [2]Fralin Biomedical Research Institute at VTC, Roanoke, VA.

The tumor protein TP53, commonly known as p53, is involved in a variety of cellular functions including apoptosis, growth arrest, and DNA repair. For these reasons, it has earned the nickname “the guardian of the genome.” Mutations in the p53 gene are often found in early- stage cancers and may be linked to metastatic processes. Post-translational modifications, such as phosphorylation and ubiquitination, direct p53’s operations in the nucleus through complex structural changes. Surprisingly, little structural information is available for full length p53 as it occurs in human cancer cells. To advance our understanding of p53 architectures in cancer cells, we used cryo-Electron Microscopy (EM) to resolve the tetramer and dimer structures of p53 derived from glioblastoma cells (U87MG line). P53-DNA assemblies were purified from U87MG cells and western blot analyses supported the presence of monomeric wild-type p53 which migrated at approximately 50 kDa. Multiple bands were visible through Comaissee-stained SDS-PAGE analysis within the 50-60 kDa region of the gel. These bands suggested the presence of post-translational modifications to p53. Additional studies revealed the presence of ubiquitinated-p53. Native gel analysis confirmed the migration of p53 tetramers that migrated ~220 kDa along with dimers that migrated ~110 kDa. Cryo-EM images confirmed a mixture of dimers and tetramers present in the preparation. We used the RELION software package to perform 3D classification and refinement procedures to produce multiple EM structures. The resulting EM maps accomodated the models of p53 and were consistent with experimentally-determined class averages calculated from the overall particle populations. Reconstructions were refined to close to 10 Å according to 0.5 Fourier shell correlation criteria. The p53 tetramer structure suggested that a continuous presence of density within the model was an intact DNA strand. Dimer structures also had extra density where two ubiquitin models were placed in a biologically-relevant manner. These features represent captured p53 assemblies performing one of their most essential functions related to DNA repair while receiving post-translational modifications. Overall, we posit that Cryo-EM can be used as a new

technique to understand medically-relevant protein targets to advance our understanding disease-related protein assemblies.

Tumor Invasion and Metastasis 1

Tissue Architectural Cues Drive Organ Targeting of Tumor Cells in Zebrafish.

C. D. Paul[1], K. Bishop[2], A. Devine[1], E. L. Paine[1], J. R. Staunton[1], S. M. Thomas[1], J. R. Thomas[1], A. D. Doyle[3], L. M. Miller Jenkins[1], N. Y. Morgan[4], R. Sood[2], K. Tanner[1]; [1]Laboratory of Cell Biology, National Cancer Institute, Bethesda, MD, [2]Translational and Functional Genomics Branch, National Human Genome Research Institute, Bethesda, MD, [3]National Institute of Dental and Craniofacial Research, Bethesda, MD, [4]National Institute of Biomedical Imaging and Bioengineering, Bethesda, MD.

Clinical patterns of cancer metastasis are non-random, with certain types of cancers preferentially metastasizing to certain secondary organs in a process termed organotropism. Genetic profiling of cancer cell lines that metastasize to the brain or bone marrow in mice have elucidated important genetic drivers of organ colonization. However, the impact of the microenvironment on organ selectivity during metastasis is less understood, particularly because of a lack of models to concurrently visualize the early stages of metastasis in multiple tissues within the same animal. Here, we used a zebrafish xenograft metastasis model to determine drivers of organ selectivity during early metastasis. The zebrafish is amenable to imaging at single-cell resolution in multiple organs in addition to possessing blood vessels on the scale of human capillaries, a brain with structural and cellular similarity to the mammalian brain, and hematopoietic tissue in the caudal vein plexus (CVP) analogous to bone marrow. Breast cancer cells that target specific murine organs (brain and bone marrow) ultimately colonized analogous tissues (brain and hematopoietic tissue in the CVP) in larval zebrafish after injection to the circulation. This pattern was conserved across human MDA-MB-231 brain- and bone marrow-targeting subclones (231BR and 231BO, respectively), brain-seeking human Bt474m1 cells, and murine 4T1 bone marrow- and brain-seeking cells. Initial cell dissemination was non-random, with more cells arresting in the complex vasculature of the CVP than the brain, but was independent of cell type, with brain- and bone marrow-targeting cells arresting at identical rates in a given organ. Similar results were obtained with inert beads and upon knockdown of β1 integrin in 231 cells. Using a combination of live-cell imaging, mechanical mapping of tissue properties, confined cell migration assays, and quantification of vascular architecture, we determined that vessel topography was the key determinant of initial cell arrest. Following arrest, a significantly higher fraction of 231BO compared to 231BR cells extravasated in the CVP, leading to the observed organ targeting. Mass spectrometry of 231BO and 231BR cells indicated that pathways involving β1 integrin were upregulated in bone marrow-targeting cells, while myosin 1B was overexpressed in brain-targeting cells. Knockdown of integrin β1 reduced extravasation in the CVP and redirected cell targeting toward the brain. Conversely, knockdown of myosin 1B decreased extravasation in the brain and lead to greater targeting of the CVP. In conclusion, while non-random targeting during initial dissemination was driven by differences in organ vasculature, organ selectivity was dependent on extravasation ability following cell arrest.

P294/B301

Tuning Cell Contractility and Vinculin Localization at Cell Junctions Is Required for Basal Epithelial Cell Extrusion.

c. Villeneuve, E. Lagoutte, S. Mathieu, L. De Plater, J. Maitre, J. Manneville, P. Chavrier, **C. Rosse**; Institut Curie, Paris, FRANCE.

Metastasis is the main cause of cancer-related deaths. How these cancer cell alterations evolve within tightly regulated tissue remains elusive. We show that an oncogenic mammary epithelial cell surrounded by normal cells could in *vivo* basally extrude and disseminate at very early stage before the formation of a primary tumor. The key polarity protein atypical PKC iota (aPKCi) overexpression is crucial for oncogenic basal cell extrusion in *vivo*, a new mechanism for early breast tumor cell dissemination. Moreover, we highlight the importance of the different mechanical properties between the oncogenic aPKCi overexpressing cells and the surrounded normal cells associated with the decrease of vinculin at the cell junction which triggers cell segregation, first step promoting and controling the direction of cell extrusion. In fact, by combining biophysical approaches, we show an increase in cell tension at the interface between aPKCi+ and WT cells dependent on myosin II activity, associated with a relocation of vinculin from cell-cell junctions to focal adhesions in aPKCi+ cells, leading to the acquisition of pro-migratory features in these oncogenic cells. We identify aPKCi and vinculin as new regulators of cell segregation and propose that a balance between cell contractility and cell-cell adhesion at the interface between normal and oncogenic aPKCi+ cells is crucial for promoting basal cell extrusion. We anticipate that this mechanism may be conserved in other carcinomas, promoting early cancer cell dissemination.

P295/B302

Spastin-Pin1 Interaction in Glioblastoma Motility.

B. Temizci[1,2], A. Karabay[1,2]; [1]Istanbul Technical University, Istanbul, TURKEY, [2]Graduate School of Science Engineering and Technology, Istanbul, TURKEY.

Glioblastoma multiforme (GBM) is the most malignant type of glioma. Since GBM has high invasion-migration capacity, it can recur rapidly after surgery. The capacity of tumor cells to migrate is attained by the formation of invadopodia that are formed through actin polymerization and further growth requires microtubule (MT) fragments which are cut into shorter pieces by MT-severing proteins from long MTs. While the expression level of the MT-severing protein Spastin is at the basal level in glial cells, its expression is increased in GBM cells. Since Spastin has been shown to localize in cell cortex where the actin is intensely located to regulate cell motility-migration, it might have an important role in the invasion of tumors. Dysregulation of proline-mediated phosphorylation mechanisms intervened by protein kinases such as cyclin-dependent kinases (CDKs) is a common phenomenon observed in cancer. Pin1 is an enzyme that leads to conformational and functional changes on its targets by isomerization of p-Ser/Thr-Pro residues. Theretofore, studies demonstrated that Pin1 may contribute to invasion mechanism by affecting proteins that trigger cell motility. Spastin has numerous Ser/Thr-Pro motifs such as T292-Pro, and T303-Pro on its microtubule binding domain (MBD). Thereupon, we suggested that the reason for the co-localization of Spastin with actin in GBM is that Pin1 may interfere with the binding of Spastin to MTs by interacting with p-Thr-Pro motifs located on the MBD. To examine whether MBD-Pin1 interaction directly affects the localization of Spastin, two different vectors containing either full-length Spastin or Spastin-MBD were cloned to identify this interaction. Through site-directed mutagenesis, Asp and Ala mutations were introduced into both Thr292 and Thr303 sites to mimic constitutively

phosphorylated and phosphorylation inhibited form of Spastin, respectively. Then, the interaction of Pin1 with wild-type and two different mutant forms of full-length Spastin or Spastin-MBD was investigated with the co-immunoprecipitation (co-IP) assay. The co-IP analysis of Spastin-MBD with Pin1 showed that Pin1 interacts with only phosphorylated form of Spastin-MBD. The co-IP between full-length Spastin and Pin1 indicated that interaction between Ala mutant of Spastin with Pin1 continues through Thr-Pro motifs located outside of the MBD, a significant increase was observed in Pin1 interaction with the Asp mutant of Spastin. All these results show that although not alone, Thr-Pro motifs on the MBD play an active role in Spastin-Pin1 interaction. To understand whether the conformational change of Spastin-MBD through Pin1 interaction is the cause of the orientation of Spastin from MTs to actins in GBM, immunocytochemical analysis will be examined in future studies.

P296/B303

Blocking Interaction between Talin2 and β1-integrin Inhibits Matrix Metalopeptidase 9 Secretion in Breast Cancer Cells.

Z. Baster[1,2], L. Li[2], C. Huang[2,3], Z. Rajfur[1]; [1]Department of Molecular and Interfacial Bophysics, Jagiellonian University, Kraków, POLAND, [2]Markey Cancer Center, University of Kentucky, Lexington, KY, [3]Department of Pharmacology and Nutritional Sciences, University of Kentucky, Lexington, KY.

Talins and integrins are key proteins in several cellular processes, including cell migration, adhesion and metastasis. We demonstrated in our previous work that in breast cancer interaction between talin2 and β1-integrin is crucial for matrix degradation, traction force generation, cell invasion (Qi et al., 2016), tumorigenesis and metastasis (Li et al., 2017). However, the molecular mechanism connecting these phenomena with talin2 and β1-integrin interaction still remains unclear. Our current research concentrates on talin2 - β1-integrin-mediated molecular mechanism of secretion matrix metallopeptidase 9 (MMP-9), that leads to extracellular matrix (ECM) degradation in breast cancer cells. We show that only fully functional interplay between β1-integrin and talin2 can provide docking site for MMP-9 containing vesicles, which is required for MMPs secretion, and consequently, to ECM degradation. Our studies, based on talin2-knockout MDA-MB-231 breast cancer cell line, indicated that depletion of talin2 inhibits secretion of MMP-9. Moreover, a single mutation in talin2 protein in Ser339, leading to a significant decrease in talin2 - β1-integrin affinity, has a similar result. Furthermore, we investigated the fate of MMP-9 in these cells, finding its accumulation in enlarged endosomes and lysosomes. These result suggest that talin2 - β1-integrin complex mediates secretion MMP-9, and a disorder in that interaction disturbs the MMP-9 trafficking process leading to overflow of a lysosomal degradation process. Li, L, Li, X, Qi, L, Rychahou, P, Jafari, N, and Huang, C (2017). The role of talin2 in breast cancer tumorigenesis and metastasis. Oncotarget 8, 106876-106887. Qi, L, Jafari, N, Li, X, Chen, Z, Li, L, Hytönen, VP, Goult, BT, Zhan, C-G, and Huang, C (2016). Talin2-mediated traction force drives matrix degradation and cell invasion. J Cell Sci 129, 3661-3674. This work is supported by a grant from National Institutes of Health Grants R01 GM122994 (to CH), and a subvention from the Polish Ministry of Science and Higher Education 2019-N17/MNS/000006 (to ZB).

Alteration of Pituitary Tumor Transforming Gene 1 (pttg 1) by Microrna Regulates Migration Ability of Human Oral Squamous Cell Carcinoma Via Mmp-2 and Mmp-9 Expression.

S. Lee[1], J. Choi[1], S. Lim[2], G. Kim[2], S. Lee[1]; [1]Gangneung-Wonju National University, Gangneung-si, KOREA, REPUBLIC OF, [2]CHA University, Seongnam-si, KOREA, REPUBLIC OF.

Human pituitary tumor transforming gene 1 (PTTG1), which is an identified proto-oncogene in pituitary tumor, highly express in the tissues with proliferating activity as well as several cancers. In the previous report, we demonstrated that PTTG1 involve in migration ability of oral SCC cell using down-regulation of PTTG1 by siRNA. However, the regulation mechanism of PTTG1 in oral SCC and PTTG1 targeted microRNA capable of regulation of their expression are still unclear. The objectives of this study are to analyze the expression of PTTG1 in oral SCC cell lines (YD-10B and YD-15) and demonstrate the effect of PTTG1 on oral SCC cell lines for the migration by PTTG1 siRNA and microRNA treatment targeted to PTTG1. In addition, the effect of PTTG1 by microRNA-186 (miR-186) and -655 (miR-655) targets to PTTG1 on migration ability of oral SCC cells was evaluated. Western blot, migration assay, and zymography were performed to evaluate the effects of PTTG1 on the expression of MMP-2/-9 and migration activity. The expression of PTTG1 in YD-10B cell line was stronger than that of YD-15 cell line. The expression of PTTG1 in both cell lines was significantly decreased without changes of their characterization in oral SCC cell lines by siRNA-PTTG1 treatment ($p<0.001$). Also, the migration abilities of both YD-10B and YD-15 were significantly decreased through decreasing MMP-2 and MMP-9 expression after siRNA-PTTG1 ($p<0.001$). Interestingly, down-regulated PTTG1 expression by siRNA differently induces to change the expressions integrin and Rho family in YD-10B and YD-15 cell lines. Furthermore, PTTG1-targeted miR-186 and miR-655 directly regulate the expression of PTTG1 and control the migration ability of oral SCC cells through regulation of PTTG1 expression ($p<0.001$). These results suggest that the alteration of PTTG1 by miR-186 and miR-655 could be controlled migration of human oral SCC cells via MMP-2 and MMP-9 expression. Therefore, these findings provide useful guideline for the migration mechanism of oral SCC by regulation of PTTG1 expression. This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education, Science and Technology (2019R1I1A3A01057886)

P298/B305

Stimulation of Glioblastoma Motility by Activated Macrophages Paracrine Signaling Involves Changes in Cytoskeletal Dynamics and Cell Morphology.

I. Fakhoury, R. Abi-Habib, M. El-Sibai; Lebanese American University, Beirut, LEBANON.

Glioblastoma multiforme (GBM) is one of the most common and deadliest primary malignant cancers of the central nervous system. The main challenge in treating GBM remains their high ability to infiltrate healthy brain tissues. GBM growth and invasion can be modulated by communication between tumor cells and their microenvironment. Microglia and infiltrating macrophages constitute up to one third of GBM tumors. We thus investigated the mechanisms by which macrophages stimulate GBM cell invasion. We first examined the effects of activated M1-type THP-1 macrophages paracrine signaling on cell motility and adhesion of U-87 MG and T98G cancer cells in *vitro*. Our results show that treatment with activated THP-1 conditioned media (CM) increases 2D cell motility and downregulates adhesion to collagen as compared to the control. Interestingly, the CM induced morphological changes in both cell lines including the formation of membrane protrusions and membrane ruffles as well as an increase in

cell-cell connecting tunnel-like structures. Quantitatively, the surface area of treated cells was around two folds larger than that of control cells, and this observed phenotype was reversed upon replacement of the CM. Further analysis by pull down assays and Förster resonance energy transfer (FRET) demonstrated a role for Rho GTPase activation in the GBM cancer cells response to treatment with CM from the activated macrophages. Altogether the data indicates that M1-type activated macrophages stimulate GBM motility in a paracrine manner by upregulating key structures involved in cell motility and invasion. Further work is still warranted to determine the molecular targets implicated in the macrophages-GBM paracrine signaling.

Stard13 Is a Tumor Suppressor in Lung Adenocarcinoma Cells That Differentially Regulates Cell Migration and Invasion through Rho Gtpases.

M. El-Sibai; Lebanese American University, Beirut, LEBANON.

Lung cancer is the second most commonly occurring cancer among both men and women. The ability to metastasize and spread to distant locations renders the tumor more aggressive. Metastasis depends on the cell's migratory ability, which requires the timely and coordinated regulation of the actin cytoskeleton. Members of the Rho subfamily of small GTP-binding proteins (GTPases) play a central role in the regulation of the actin cytoskeleton and in cancer cell migration and metastasis. The switch between active GTP-bound and inactive GDP-bound state is regulated by guanine nucleotide exchange factors (GEFs), GTPase-activating proteins (GAPs) and guanine-nucleotide dissociation inhibitors (GDIs). Here we studied the role of the RhoA/Cdc42 GAP StarD13, a previously described tumor suppressor, in malignancy, migration and invasion of lung the cancer cells A549. The decrease in the level of expression of this Rho-GAP in tumor tissues compared to non-patients suggested it is indeed a tumor suppressor in lung cancer. Knocking down StarD13 through transfecting A549 cells with StarD13 siRNA, led to an increase in cell viability, seen by WST, cell cycle analysis and an nexin staining. StarD13 however was required for cell migration. In fact, StarD13 knockdown resulted in an inhibition of cell motility by wound healing and time lapse random migration.StarD13 siRNA-transfected cells were not able to detach their tail and move forward. This was due to the constitutive activation of RhoA seen by pull down assay and FRET. StarD13, however, was found to be an invasion suppressor in an invasion assay. This was due to its inhibitory role of Cdc42-mediated invadopodia. Indeed when StarD13 was knocked down, Cdc42 activation increased and invadopodia formation seen through TKS4 staining increased as well. This was reversed with Cdc42 knockdown. In conclusion, StarD13 has different effect on lung cancer cell migration and invasion through its regulation of Rho GTPases.

Ror1 Signaling through Dvl and Rif Promotes Invasion of Lung Adenocarcinoma Cells.

M. Nishita[1,2], K. Kamizaki[2], I. Nishikaku[2], H. Shibuya[3], K. Matsumoto[4], Y. Minami[2]; [1]Fukushima Medical University, Fukushima, JAPAN, [2]Kobe University, Kobe, JAPAN, [3]Tokyo Medical and Dental University, Tokyo, JAPAN, [4]Kanazawa University, Kanazawa, JAPAN.

Ror1 receptor tyrosine kinase mediates Wnt5a-induced signaling, thereby regulating tissue-/organo-genesis during embryonic development. Ror1 is also expressed highly in various types of cancer cells and promotes their proliferation, invasion, and metastasis, depending on their cell types. However, it is unclear whether Ror1 regulates these processes by acting as a Wnt5a receptor in cancer cells. Here, we

show that lung adenocarcinoma PC-9 cells express both Wnt5a and Ror1, leading to constitutively activated Wnt5a-Ror1-Dvl signaling, which is required for their invasiveness. We also show that Ror1 induces formation of filopodia through the Rho-family small GTPase, Rif (rho in filopodia, also known as RhoF). Interestingly, Rif-mediated filopodia formation is highly polarized and associated with degradation of Matrigel during invasion of PC-9 cells. In fact, suppressed expression of Rif in PC-9 cells inhibits their invasiveness. We will discuss how Rif-mediated filopodia formation can associate with Wnt5a-Ror1-Dvl signaling to promote cancer cell invasion.

The Roles of Actin Regulators in Transendothelial Migration of Uveal Melanoma Cells.

M. D. Onken, J. A. Cooper; Washington University, Saint Louis, MO.

Uveal melanomas (UM) are cancerous tumors arising from melanocytes in the pigmented layers of the eye - the iris, ciliary bodies, and choroid - collectively called the uvea. UM cells can only spread hematogenously through the bloodstream, but they enter the bloodstream readily: nearly half of UM patients die of metastatic disease; and circulating UM cells are detectable in patients who never develop metastatic disease. We have focused on extravasation, specifically transendothelial migration (TEM), of UM cells as the essential first step in metastatic progression. We have shown that UM cells execute TEM via a stepwise process: UM cells adhere to the luminal surface of endothelial cells; they intercalate into the endothelial monolayer and remain intercalated, often for hours; they then extend actin-rich protrusions beneath the monolayer, and then detach and migrate away under the endothelial monolayer. Genetically: UM tumors are driven by oncogenic mutations in *GNAQ* or *GNA11* in 90% of cases; and tumors that subsequently lose the tumor suppressor *BAP1* have a >80% chance of metastasizing. G-alpha-q/11 activates TRIO, a guanine nucleotide exchange factor (GEF) for both RhoA and Rac1 small GTPases. BAP1 regulates the transcription of Rac1, cortactin, and several RhoA GTPase activating proteins (GAPs). We are using specific inhibitors to define the roles of Rho and Rac activation in TEM of GNAQ(Q209L), BAP1 wt UM cells and CRISPRs to link their effects on TEM to BAP1 loss. We are also using RhoA and Rac1 FRET biosensors to quantify the cellular localization of activation of each during TEM. Our findings suggest that the G-alpha-q/11 and BAP1 pathways intersect at these key regulators of motility and migration to drive TEM in UM cells.

Ccl18-elicited Phosphorylation of Acapin Steers Breast Cancer Cell Migration and Metastasis.

X. Liu[1], M. Mullen[1], N. Zohbi[1], F. Yang[2], S. Muthusamy[2], **X. Yao**[2]; [1]Morehouse School of Medicine, Atlanta, GA, [2]Cellular Dynamics, Hefei, CHINA.

Tumor metastasis represents the main causes of cancer-related death. Our studies show that ARF6 GTPase-activating protein ACAP4 regulates directional breast cancer cell migration in response to chemokine CCL18 (Chen, 2011. *Cancer Cell*; Song, 2018. *JMCB*). Here, we report a critical mechanism of action underlying Akt signaling in promoting breast cancer metastasis. Using functional proteomics screen, we identified a novel ARF6-ACAP4 signaling regulator, Acapin, which inhibits the GAP activity of ACAP4 to promote ARF6-GTP in *vitro*. CCL18 stimulation elicited Akt signaling which recruits Acapin to the lamellipodium membrane via phosphorylation of Acapin. Importantly, Akt-induced phosphorylation of Acapin promotes the binding of Acapin to ACAP4 which elevates ARF6-GTP level. Acapin was also found to be required for efficient CCL18-Akt stimulation of directional cell migration *in vitro* and breast

cancer metastasis in xenografts. Significantly, elevated level of phopho-Acapin correlates with increased levels of phospho-Akt and ARF6-GTP as well as poor prognosis in patients with advanced/metastatic breast cancer. Our results demonstrate that Acapin relays CCL18-elicited Akt signaling cascade and is a key determinant in chemokine-stimulated breast cancer metastasis.

P303/B310

Chromatin Remodeling Drives Metastatic Potential of Bladder Cancer Cell Lines.

S. KIM, 20892[1], L. Varticovski[1], S. Baek[1], M. Nickerson[2], C. Redon[3], Q. Lao[1], M. Dean[2], L. Prokunina-Olsson[2]; [1]NCI, NIH, Bethesda, MD, [2]LTG, DCEG, National Cancer Institute, NIH, Bethesda, MD, [3]DTP, NCI, NIH, Bethesda, MD.

Given the difficulty to treat metastatic bladder cancer (BC), it is critical to identify tumors with metastatic potential. Previous studies suggested that epigenetic alterations play essential roles in changing transcription during cancer progression. However, how BC cells establish an altered epigenetic landscape and the relationship to metastasis remains mostly unknown. Thus, we investigated how the genome-wide chromatin landscape evolves during BC progression by surveying genome-wide DNase hypersensitivity sites (DHS) in 16 BC cell lines with various metastatic potential as a readout of epigenetic activities. The DHS profiles showed large-scale alterations with recurrent loss of chromatin accessibility during metastatic progression, mainly affecting non-promoter DHS. Most of the lost DHS were unique to normal urothelial cells indicating the loss of cell identity. Ingenuity Pathway an alysis identified SMARCA4 as the top upstream transcription regulator of the potential target genes regulated by the recurrently lost/gained DHS in metastatic BC. A novel homozygous SMARCA4 deletion of several exons was found in metastatic cells of the T24 lineage. Suppressed SMARCA4 expression was also evident in two other metastatic lineage cells, UMUC3/LUL2. Although we found no SMARCA4 alteration in other metastatic cells - 253J, BV and PDX, other SWI/SNF subunits were affected. 253J/BV and PDX carried homozygous nonsense mutations in SMARCB1 and ARID1A, respectively. In contrast, no homozygous alterations in 12 other components of SWI/SNF complexes were found in 6/6 non-metastatic BC cell lines. In the TCGA database, of the 12 genes that encode components of the SWI/SNF complex, seven genes had low expression or truncating mutations in at least two bladder tumors, and some of SWI/SNF complex subunits showed a trend for association with reduced PFS individually or in combination of all three genes ($p < 0.01$). Low expression/protein-truncating mutations in the three genes were significantly more common in stage 3-4 tumors compared to stage 1-2 tumors ($p < 0.01$). In summary, our study showed that loss of function alterations in SWI/SNF subunits is associated with large-scale recurrent loss of DHS in metastatic BC cell lines and poor clinical outcomes/higher tumor stage in TCGA BC patients, confirming the importance of altered genome structure and chromatin remodelers for the metastatic potential of BC.

P304/B311

3D Genome Organization Changes Associated with Melanoma Confined Migration.

R. Golloshi, 37916, R. Patton McCord; University of Tennessee, Knoxville, TN.

To migrate through constrictions of the extracellular matrix or endothelial lining, cells must dramatically squish and squeeze their nuclei, causing major deformations. The size and stiffness of the nucleus constitutes a rate limiting factor during migration. Despite the detailed characterization of the 3D genome organization, it is not yet known whether a specific organization influences or is affected by

constricted migration. Using melanoma (A375) as a model of metastasis, we have identified an inherent heterogeneity in migratory competence of these cells. Through sequential rounds of constricted migration, we have been able to isolate subpopulations of A375 that are poor migratory (A375-NM) and highly migratory (A375-M). Interestingly, as A375-M cells progressed through rounds of constricted migration, they displayed a stable increase in migration efficiency suggesting inherent changes in chromatin organization and gene expression. Using Hi-C to measure 3D genome structure, we found that A375-M exhibit a distinct genome organization with specific regions of the genome that switch compartments when compared to A375-NM. Some of these changed regions correspond to genes correlated with metastatic progression. By integrating imaging and multi omic data analysis, we are able to characterize the interplay between gene expression, epigenetics and global changes in genome organization during confined migration. These observations reveal a previously unidentified relationship between the 3D organization of the genome and ability of melanoma cells to migrate through constricted spaces.

P305/B312

Overexpression of Nuclear Envelope Proteins in Metastatic Melanoma Promote Loss of Nuclear Envelope Integrity during Confinement.

M. A. Baird[1,2], A. X. Cartagena-Rivera[3], M. Pirooznia[1], R. S. Fischer[1], C. M. Waterman[1]; [1]National Heart, Lung, and Blood Institute, NIH, Bethesda, MD, [2]University of Maryland, College Park, MD, [3]National Institute on Deafness and Other Communication Disorders , NIH, Bethesda, MD.

Metastatic melanoma is an aggressive disease, characterized by its high level of mutational burden, resistance to traditional chemotherapies, and rapid metastasis, the primary cause of melanoma mortality. To metastasize to a distal site, cells must migrate through tissues which impose physical constraints, and regions of high confinement, resulting in nuclear deformation and loss of nuclear envelope (NE) integrity. This exposes chromatin to cytosolic DNases, generating double strand breaks, that when repaired improperly result in heritable genomic aberrations. We hypothesize that during metastatic progression, the expression levels of genes encoding NE proteins are altered, promoting nuclear deformability and envelope fragility, endowing cells with a greater ability to migrate in confinement and driving genomic plasticity. To determine the changes in NE gene expression during disease progression, we compared published RNA-seq transcriptomic data sets from patient tumor samples of metastatic BRAF V600E melanoma and benign nevi, metastatic melanoma cell lines, and primary human melanocytes, focusing on a subset of NE proteins transcriptionally upregulated in metastatic disease. To determine their role in modulating nuclear integrity during confinement, we performed a targeted siRNA-based screen of 10 genes and assayed for nuclear fragility using a pressure-driven PDMS confinement device to rapidly and precisely confine cells bearing fluorescent markers of histones, nuclear membranes, DNA exposure to the cytosol, and a diffusible nucleoplasmic marker. We found that under 3 μm confinement 35.4% of melanoma cell line 1205Lu exhibit DNA exposure to the cytosol, compared to only 10.1% of melanocytes. Reduction of NE proteins Lamin B2 and Lamin B Receptor (LBR) in 1205Lu cells reduced DNA exposure to the cytosol to 8.2% and 5.7% respectively. To determine if nuclear mechanics were affected, we utilized atomic force microscopy combined with a laser scanning confocal to analyze nuclear stiffness. We found that melanocytes have a dramatically stiffer nucleus compared to metastatic melanoma lines, however overexpression of LBR was sufficient to reduce nuclear stiffness in melanocytes. These results show that upregulation of specific NE proteins in metastatic melanoma promote confinement-induced NE fragility, and can play a role in altering nuclear

mechanical properties, potentially promoting genetic heterogeneity in metastatic melanoma during migration in confined microenvironments.

P306/B313

Protumorigenic Mechanisms of LCN2 Action within the Premetastatic Lung.

F. Sanchez, N. Nadales, A. Aguayo, C. J. Geller, J. A. Kelber; California State University Northridge, Northridge, CA.

Mortality for patients with metastatic breast cancer is over 60% at five years post-diagnosis. Thus, there is a critical and urgent need to identify targetable mechanisms that support breast cancer cell dissemination to and expansion within the metastatic niche. In this regard, previous work has established mechanisms by which cancer cells prime these premetastatic tissues, and we recently established a tumor cell-free syngeneic in *vivo* breast cancer model for characterizing tumor cell secretome-mediated reprogramming of premetastatic tissues. Using this model, we reported that secretomes from metastatic breast cancer cells, enriched for a prognostically unfavorable lipocalin 2 (LCN2) axis, induced anti-inflammatory MSC actions and a tumor-supportive premetastatic lung. Interestingly, previous work has demonstrated that LCN2 expression in hypoxic murine kidneys requires deoxyhypusine synthase (DHPS)-dependent hypusination/activation of the eukaryotic translation initiation factor 5A (eIF5A1/2) - an established tumorigenic node. Thus, we asked whether eIF5A1/2 activity is necessary for LCN2 expression in metastatic breast cancer cells. Notably, LCN2 expression in the metastatic triple-negative Py230 breast cancer cells was abrogated following treatment with a DHPS inhibitor. To further characterize potential LCN2 regulatory and/or effector pathways, we analyzed the prognostic significance for a focused set of common eIF5A1/2 and tumor heterogeneity markers. Of these proteins, only genomic alterations in LCN2 or HSPA5 (GRP78 or BiP) genes significantly correlated with decreased median survival of breast cancer patients. In combination with our ongoing studies aimed at identifying Py230 secretome-induced transcriptome changes within the premetastatic lung, these data promise to identify novel targetable mechanisms by which primary breast tumors communicate with the premetastatic niche to promote breast cancer progression and patient mortality.

The Eif5a1/2 Pathway Mediates Tgfb/fn1-induced Metastasis and Associates with Prognostically Unfavorable Sox2/tp53 Genomic Alterations in Breast Cancer Patients.

C. Geller, R. Güth, Y. Adamian, J. Maddela, L. Kutcher, M. Agajanian, S. Kim, K. Bhakta, J. A. Kelber; California State University, Northridge, Northridge, CA.

Metastatic breast cancers carry a 5-year survival prognosis of less than 20%. Thus, it is highly desirable to identify therapeutic strategies that specifically target both primary and metastatic tumors. It is generally accepted that epithelial-mesenchymal transition (EMT) is an important regulator of therapy responsiveness, contributing to intratumoral heterogeneity and systemic dissemination in solid tumor types such as breast cancer. Since we have previously reported that posttranslational hypusination of eukaryotic Initiation Factor 5A (eIF5A1/2) is required for Pseudopodium-Enriched Atypical Kinase One (PEAK1) translation and PEAK1 mediates malignant phenotypes of Transforming Growth Factor β (TGFβ) signaling, we hypothesized that TGFβ may directly regulate eIF5A1/2 activity during EMT and that targeting this pathway may effectively impair metastatic breast cancer cells. We show evidence of an active eIF5A/PEAK1 pathway in undifferentiated, mesenchymal breast cancer tissue. Notably, inhibition

of eIF5A hypusination blocks PEAK1 translation, cell viability, and TGFβ/fibronectin-induced EMT and metastasis of breast cancer cells. Further, assessment of subcellular eIF5A1/2 in response to inhibitors of the hypusination pathway revealed cell line-dependent patterns that suggest eIF5A1/2 functions to drive intercellular heterogeneity. Using a gene set defined by PEAK1-induced EMT and eIF5A1/2 pathway markers, we generated an instructive interactome containing 12 nodes represented in the initial gene set and an additional 74 interacting nodes. Bioinformatic analyses identified SOX2 and PT53 as DHPS interactors within this PEAK1-eIF5A1/2 interactome that significantly contribute to diminished patient survival when genomically altered in combination with DHPS. Taken together, these results suggest that combinatorial therapies targeting DHPS and PEAK1-SOX2/TP53 axes may reduce intratumoral heterogeneity and improve breast cancer outcomes.

P308/B315

Dietary Soy Isoflavone Metabolite Equol Regulates Translation Initiation Factors to Promote Metastatic Breast Cancer Progression.

A. M. Cruz-Collazo[1], C. de la Parra[2], R. J. Schneider[2], S. Dharmawardhane[1]; [1]University of Puerto Rico - Medical Sciences Campus, San Juan, PR, [2]New York University - Cancer Institute, New York, NY.

Protein synthesis initiation plays an important role in post transcriptional regulation. The eukaryotic initiation factor 4G1 (eIF4G1) is known to be overexpressed in breast cancer cells, and thus, to promote the expression of pro-cancer molecules. In previous studies, we reported that in a breast cancer metastasis mouse model, daidzein increased breast cancer progression and that in vitro, its metabolite equol is primarily responsible for daidzein's cancer promoting effects via upregulation of eIF4G1. Also, a polysome profile study demonstrated that equol upregulated eIF4G-depepndent non-canonical protein synthesis of a number of pro-cancer molecules. Since downregulation of eIF4G did not completely abrogate the effects of equol in breast cancer cells, we asked the question whether equol regulates other initiation factors such as DAP5, a homolog of eIF4G1. To validate the effect of equol in vivo and to investigate its effect on protein synthesis initiation, we created cell lines with stable knockdown of eIF4G1 via a Tetracycline-inducible promoter driving a short hairpin RNA (shRNA) targeting eIF4G1. Next, the MDA-MB-435 metastatic cancer cells expressing control or eIF4G1 knockdown were used to create mammary fat pad tumors in immunocompromised SCID mice. Doxycycline (50 mg/kg BW) was administered to selected groups via oral gavage to induce the expression of sh-eIF4G1 after tumor establishment. Also, Vehicle (90% corn oil, 10% ethanol) and equol (10 mg/kg BW) were given via oral gavage. All treatments were administered 3X week for a total of 65 days. Data shows that equol increases mammary tumor growth when compared to the vehicle. Also, western blot analysis of the tumors show that Dap 5 was expressed even after eIF4G1 knockdown. This was validated also in-vitro. This data suggests that there may be a compensation effect by DAP5 to protein synthesis initiation when eIF4G1 is knocked down in metastatic cancer cells. In conclusion, eIF4G1 knockdown abolishes the effect of equol in cancer progression. This validates our hypothesis that equol increases breast cancer progression via regulation of protein synthesis initiation. Future studies will determine the effect of equol in metastatic cancer cells following knockdown of the homologous protein synthesis initiation factors eIF4G1 and Dap5.

P309/B316

Rab13 and Net1 Mrna Localization and Roles during Collective Invasion.

G. Chrisafis, S. Mili; National Cancer Institute, NIH, Bethesda, MD.

Targeting of mRNAs to specific subcellular regions, and the ensuing spatial regulation of protein production, is important for various processes, including migration, epithelial cell polarity, and neuronal function. Our lab has described a pathway of mRNA localization that targets a group of ~80 mRNAs to cell protrusions. Disrupting this localization mechanism impairs single-cell migration on 2-dimensional surfaces as well as invasion through a 3-dimensional matrix. Among these protrusion-localized mRNAs, we focus on two, which encode Rab13, a small GTPase with a role in intracellular membrane trafficking, and Net1, a guanine nucleotide exchange factor (GEF) for the RhoA GTPase. Here, we explore the role of Rab13 and Net1 RNA localization in collectively invading cancer cells, characterized by the maintenance of cell-cell contacts. We recapitulate collective invasion using MDA-MB-231 breast cancer spheroids, which become invasive upon withdrawal of serum. We performed RNA FISH to assess the distributions of Rab13 and Net1 RNAs in invading spheroids, and developed a novel method of quantifying and statistically analyzing the distributions. Interestingly, we find that both the Rab13 and Net1 mRNAs localize to the front edge of leader cells in invasive strands. To disrupt this distribution, we employed a method that we recently developed. This method relies on antisense oligonucleotides that specifically target localization elements contained within the 3' UTRs of the Rab13 and Net1 RNAs. Indeed this approach can specifically prevent the polarized distribution of the RNA being targeted (either Rab13 or Net1) within the leader cells of invasive strands. Interfering with this distribution also causes a decrease in spheroid invasiveness, suggesting that the distribution of the Rab13 and Net1 RNAs plays an important functional role in the ability of spheroids to invade. We are utilizing these techniques to investigate the mechanisms underlying Rab13 and Net1 RNA localization and to assess the functional effects of local GTPase regulation during collective invasion of cancer cells. Moving forward, we are also interested in testing if delivery of morpholinos that prevent Rab13 or Net1 RNA localization can reduce metastasis in in vivo models.

P310/B317

The Effect of PTHrP on the Alcohol-induced Proliferation, Invasion and Migration of Mcf-7 and Mda-231 Cells.

M. Dunbar, I. Shibley; Pennsylvania State Univ/Berks Campus, Reading, PA.

Epidemiological and experimental studies have shown a link between moderate alcohol consumption and an increased risk of breast cancer in women. In estrogen receptor positive cells (ER+) alcohol affects estrogen signaling which leads to an increase in cell proliferation, invasion and migration. However, the effects of alcohol on estrogen receptor negative cells are not as well understood. Parathyroid hormone related protein (PTHrP) is a paracrine growth factor that has been shown to be a potential regulator of estrogens' effects in the mammary gland. Overexpression of PTHrP in the mammary gland inhibits estrogen induced growth of the mammary gland during puberty. In the present study we the effects of PTHrP on the alcohol induced cellular responses of ER positive (MCF-7) and ER negative (MDA-MB-231) breast cancer cells were analyzed. Results showed that alcohol lead to an increase in the invasion and migration of both cell types. However, alcohol treatment increased cellular proliferation only in ER+ MCF-7 cells. Pre-treatment with PTHrP inhibited the alcohol induced proliferation of MCF-7 cells. Pre-treatments with PTHrP did not alter invasion or migration of either cell type. Together these results

suggest that alcohol induce cellular proliferation, but not invasion and migration, is due in part to the activation of estrogen receptor signaling and that this activation can be inhibited by PTHrP.

P311/B318

Ultrastructural an alysis of Inflammatory Breast Cancer Cell Clusters in an Environment Mechanically Mimicking the Lymph Vascular System.

Y. Fujii[1], S. Krishnamurthy[2], R. El-Zein[1]; [1]Houston Methodist Research Institut, Houston, TX, [2]MD an derson Cancer Center, Houston, TX.

Background: Inflammatory breast cancer (IBC) is a rare form of breast cancer that is highly aggressive and is associated with a poor prognosis. The disease rapidly metastasizes, and more and larger clusters of cancer cells are found both in the circulation and in the lymph vascular systems in IBC patients as compared to other breast cancer (non-IBC) patients. We hypothesized that the formation of these clusters plays a pivotal role in IBC metastasis and its rapid progression, and that their structure and function may be key to identifying molecular differences between IBC and non IBC. To date, little is known about the differences between the ultrastructure of IBC and non-IBC clusters. **Methods:** Mechanical methods were used to generate clusters of IBC cells (SUM149 and IBC3), non-IBC cells (MDA-MB-231, MDA-MB-468, and MCF7), and human mammary epithelial cells (MCF10A) by adding 2.25% of PEG8000 to the media in order to mimic the lymph fluid viscosity. Clusters were made in bacterial dishes by shaking at 40 rpm for 72 hours using a belly button dancer shaker in the CO2 incubator, then analyzed by light microscopy or prepared for and observed by transmission electron microcopy (TEM). **Results:** Significant differences were seen between IBC and non-IBC cell clusters, both by light microscopy and TEM. Light microscopy analyses revealed that IBC cells form more compact clusters than non-IBC cells. The TEM analysis revealed that IBC cells harbor numerous microvilli and microvesicles, both on the free, outer surface of the cluster as well as on the surface of cells inside the cluster. Microvilli from IBC cell clusters were both longer than those of non-IBC cell clusters and at a higher density. Dead cells were observed in the non-IBC clusters but not in IBC clusters. In addition, SUM149 cells had multiple lipid droplets in the cytoplasm. IBC3, MDA-MB-231, MCF7 and MCF10A had a few lipid droplets but not nearly as many as SUM149 cells. **Conclusions:** Cell clusters formed by both IBC cell lines, SUM149 and IBC3, exhibited a distinct ultrastructural disposition characterized by the presence of long, crowded microvilli, which was not seen in cell clusters of any other non-IBC and normal mammary epithelial cells. These microvilli may play an important role in IBC's aggressiveness compared to non-IBCs. To our knowledge, this is the first study that demonstrates the morphological differences between IBC and non-IBC cell clusters.

P312/B319

Toll Like Receptor 4/Nuclear Factor Kappa B Signaling Pathway Activation Promotes the Migration of Triple Negative Breast Cancer Cells: Inducible Nitric Oxide Synthase Role.

K. Ruiseco Flores, E. Monjaraz Guzmán, M. J. López Cuevas; Benemérita Universidad Autónoma de Puebla, Puebla, MEXICO.

Toll-like receptors (TLRs) are members of the interleukin-1 receptor (IL-1R) superfamily, play a crucial role in the inflammation and innate host defense against invading microorganisms. Toll-like receptors (TLRs) have garnered an extraordinary amount of interest in cancer research due to their role in tumor progression, invasion, survival, and metastasis. Moreover, proinflammatory pathways include several

genes that promote tumorigenesis by inducing the production of inflammatory mediators as inducible nitric oxide synthase (iNOS) and nitric oxide (NO). Accumulating evidence suggests that iNOS is involved in multiple aspects of breast cancer, including proliferation, migration, invasion, angiogenesis and response to chemotherapy. However, little research has investigated the role TLR4 activation on the migratory capacity of triple negative breast cancer cells. The aim of this research was to investigate role of TLR-4/NF-κB/iNOS signaling pathway in triple negative breast cancer cell migration. In this study, experimental evidence suggest that TLR-4 activation promotes migratory capacity of MDA-MB-231 cells, through microenvironment pro-inflammatory stimulus iNOS. TLR-4 activation by LPS, up-regulated migration (fold change ~1.5) by transwell assay and wound healing assay, through NF-κB/iNOS-dependent mechanism. Sodium Selenite (Na_2SeO_3), a NF-κB inhibitor, prevent LPS-stimulate migration and reduces expression of iNOS. LPS-stimulated MDA-MB 231 cells migration capacity is reduced in the presence of 1400W, selective iNOS inhibitor. These findings indicated a pro-migratory function that TLR4/NF-κB/iNOS signaling pathway, activated by LPS, in human breast cancer and provide a potential therapeutic target.

P313/B320

Interleukin-22 Involves in Bone Metastasis of Breast Cancer by Inducing Sphingosine-1-phosphate in Mesenchymal Stem Cell.

J. Kim, E. Kim, B. Choi, S. Park, S. Oh, H. An , E. Chang; University of Ulsan College of Medicine, Seoul, KOREA, REPUBLIC OF.

Interleukin-22 (IL-22) signaling pathway has been well established to be involved in various cancer cell progressions, however, the role of IL-22 in bone metastatic breast cancer. Here, we found that bone metastatic breast cancer displays elevated expression of interleukin-22 receptor 1 (IL-22R1) and sphingosine-1-phosphate receptor 1 (S1PR1) from the GEO profiling. IL-22 stimuli promoted the expression of IL-22R1 and S1PR1 in aggressive MDA-MB-231 breast cancer cells. IL-22 treatment increased sphingosine-1-phosphate (S1P) production in mesenchymal stem cells and that induced S1P-mediated chemotactic migration of MDA-MB-231 cells. This effect was inhibited by S1PR1 antagonist. These results indicate the potential role of IL-22 in bone microenvironmtent to drive bone metastasis of breast cancer, suggesting that IL22R1-S1PR1 axis can be a potential biomarker and diagnosis in bone metastatic breast cancer.

Reduction of Complex Type N-glycans Suppress Neuroblastoma Cellular Properties.

R. A. Schwalbe, M. K. Hall, A. A. Whitman, D. A. Weidner; East Carolina Univ-Brody Sch Med, Greenville, NC.

Tumor development and progression are accompanied by changes in N-glycans attached to proteins. Many secreted and membrane proteins undergo N-glycosylation, and thereby modifications in glycan processing can affect cell signaling events. Here we investigated the role of N-acetylglucosaminyltransferase-II (GnTII, *Mgat2*) protein substrates in aberrant neuronal properties of neuroblastoma (NB) cells. *Mgat2* was silenced in a human NB cell line (HuNB) to generate a novel cell line, HuNB(-*Mgat2*), which lacked complex type N-glycans, as in a rat NB cell line. Changes in the types of N-glycans were confirmed by lectin binding assays in the HuNB and HuNB(-Mgat2) cell lines, along with the rescued cell line, HuNB(-/+*Mgat2*). Further western blotting of the various cell lines

heterologously expressing a voltage-gated K+ channel (Kv3.1b) showed that N-glycans of Kv3.1b could be processed to complex type in the rescued cell line. In comparing HuNB and HuNB(-*Mgat2*) cell lines, we showed that the presence of complex type N-glycans enhanced anchorage-independent cell growth, cell proliferation and cell invasiveness, while they diminished cell-cell interactions as observed in the rat NB cell line. Cell proliferation, invasiveness and adhesion of the rescued cell lines were more like the parental cell lines than the glycosylation mutant cell lines. Further Western blotting revealed increased protein levels of MMP-2, EGFR, and Gab2 in both parental NB cell lines relative to the glycosylation mutant cell lines, and also, gelatin zymography studies demonstrated that the higher MMP-2 protein levels correlated with higher MMP-2 activity. Thus, our results support the necessity of complex type N-glycans in the promotion of cell proliferation and cell invasiveness in NB via the remodeling of the ECM and EGFR signaling pathway.

P315/B322

SNX27-retromer Assembly Recycles MT1-MMP to Invadopodia and Promotes Breast Cancer Metastasis.

P. Sharma[1], S. Parveen[1], L. V. Shah[1], M. Mukherjee[1], Y. Kalaidzidis[2], A. J. Kozielski[3], R. Rosato[3], J. Chang[3], S. Datta[1]; [1]Indian Inst Sci Education/Bhopal & Research, Bhopal, INDIA, [2]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, GERMANY, [3]Houston Methodist Research Institute, Houston, TX.

Tumor metastasis involves a complex sequence of events that facilitate the movement of the tumor cells by breaking the underlying extracellular matrix (ECM). It is composed of macromolecules mainly proteins that are densely packed like mesh-fibers that act as a physical barrier for the cellular movement. To move across the ECM, specialized actin-rich membrane protrusive structures named invadopodia are formed by the metastatic cells. Proteases that can degrade components of ECM are recycled from intracellular compartments to invadopodia for efficient degradation. This research work was aimed to study the molecular machinery governing the recycling of the proteases and thus facilitate cancer cell invasion. In the metastatic breast cancer cell line, MDA-MB-231, we found that retromer regulates the matrix invasion activity in association with sorting nexin 27 by recycling matrix metalloprotease, MT1-MMP on the cell surface. Also, MT2-MMP, another most abundantly expressed MMP, was found to be invadopodia associated in this cell line and contributes to its invasive potential. Although MT1 and MT2-MMP showed a high degree of colocalization, they were located on the distinct endosomal domains when analyzed by super-resolution microscopy. TIRF microscope-based analysis revealed that retromer and SNX27 could selectively recycle MT1-MMP but not MT2-MMP. They phenocopied each other in facilitating matrix degradation and associating with MT1-MMP. Furthermore, the in *vitro* interaction studies via pull-down and Isothermal Titration Calorimetry revealed that both SNX27 and retromer could directly interact with MT1-MMP. However, in the in *silico* analysis, among retromer and its family members, SNX27 was found to be overexpressed or profoundly altered in the patients having invasive breast cancer. In Xenograft based studies, SCID mice engrafted with SNX27 knockout cell line showed prolonged survival, suggesting possible implication for over-expression of the sorting nexin in tumor samples. These findings highlight a novel role of sorting machinery in the breast cancer cell invasion via mediating trafficking of the proteases.

Invasive Growth Response to DNA Repair Stress.

A. Marz, 23504, B. Hayes, T. Riddick, M. Cowell, A. Desamy, A. Hart, I. Whilby, C. Smith, S. Scott; Norfolk State University, Norfolk, VA.

Saccharomyces cerevisiae exhibits yeast form growth on rich media but some strains of *S. cerevisiae* switch to invasive growth when nutrient deprived. Our goal is to investigate the mechanism that causes invasion in *S. cerevisiae.* Specifically, we focus on DNA repair response pathways that intersect with invasive growth response pathways, based on our previous results in breast cancer cell invasiveness. Previously, we showed that transient and short-term downregulation of the expression of the DNA repair genes MRE11, RAD50, XRCC3, or RAD51 enhanced cell invasiveness in human breast cells. Here, we ask whether genetic or environmental factors that enhance or reduce DNA damage repair responses alter filamentous or invasive growth in yeast. We find that inducing DNA repair stress by a heterozygous deletion of RAD50 in an invasive strain of yeast enhances invasiveness, while challenging an MRE11 heterozygote that is non-invasive with caffeine-induced damage renders it invasive. Furthermore, mutant yeast strains with enhanced resistance to death by caffeine-induced damage display increased adhesion. Heterozygous deletion of RAD51 in invasive yeast renders it non-invasive when treated with resveratrol known to reduce oxidative damage in cells, while a significant reduction in RAD51 expression is observed in the heterozygous delete mutants of the flocculation gene FLO8 which is required for filamentous growth in diploid yeast. These results support the hypothesis that cells can be induced to become more invasive by providing a threshold level of damage to induce stress pathways relevant for filamentous and invasive growth, and provide candidate genes involved in this process.

P317/B324

Loss of Awp1 Leads to Enhanced Cell Motility of Breast Cancer Cells.

S. PARK, E. Kim, B. Choi, H. An , J. Kim, S. Oh, K. Jang, E. Chang; Asan Medical Center, University of Ulsan College of Medicine, Seoul, KOREA, REPUBLIC OF.

Metastatic breast cancer is leading cause of cancer-associated deaths in women worldwide, however, the prognosis for detection of early stage breast cancer go on to develop metastatic disease is still lacking. Therefore, targeting tumor cell motility is one of strategies to improve the outcome for poor prognosis in patients with breast cancer. Here, we found that AWP1 (ZFAND6, zinc finger AN1 type-6) expression level is lower in the aggressive breast cancer cells compared with non-aggressive breast cancer cells. AWP1 knockdown using short hairpin RNA in non-aggressive MCF7 cells promoted cell motility. Furthermore, CRISPR/Cas9-mediated AWP1 knockout led to morphological changes towards a mesenchymal cell type and also accelerated the invasion of MCF7 cells. Our findings suggest that loss-of-function of AWP1 promotes the migration capacity of breast cancer cells, linking to the cancer invasion and further formation of metastasis.

P318/B325

Phenotypical and Signaling Pathway Alterations in Fibroid Cells Following Continuous Cadmium Exposure and the Implications in Carcinogenesis.

Y. Yan, M. J. Dykstra, L. Yu, L. Castro, J. Liu, C. J. Tucker, E. Scappini, D. Dixon; National Institute of Environmental Health Sciences, NIH, RTP, NC.

Background: the heavy metal Cadmium (Cd), a widespread environmental contaminant, poses serious hazards to human health. We found that Cd can act as a metalloestrogen, stimulating growth of hormonally responsive human uterine leiomyoma (ht-UtLM; fibroid) cells. In women of reproductive age, a statistically significant association between blood Cd levels and fibroid volume has been observed. Prolonged exposure to Cd and Cd-containing substances, such as cigarette smoke, is thought to contribute to cancer progression. **Objective:** the aim of this study was to determine if benign fibroid cells could be altered in *vitro* by continuous Cd exposure. **Experimental Design:** Fibroid cells were exposed to 10 µM $CdCl_2$ for 8-weeks to evaluate the impact of Cd exposure. **Methods: the** Cd exposed cells were analyzed by time-lapse confocal imaging, flow cytometry, transmission electron microscopy, Ki-67, and soft agar assays. Total RNA was extracted and analyzed using NanoString PanCancer Progression/Pathways Panels. **Results:** When fibroid cells were exposed to 10 µM $CdCl_2$ for 8 weeks, a robust and fast-growing Cd Resistant LeioMyoma culture (abbreviated as CR-LM) was established. CR-LM cells contained increased cytoplasmic aggregates of glycogen at the cell periphery and had significantly enhanced cell motility compared to passage-matched controls. A higher percentage of CR-LM cells were in the G2/M phase of the cell cycle and had dramatically increased Ki-67 (a proliferation marker) labeling indices. CR-LM cells were able to form viable colonies in soft agar thus exhibiting anchorage-independent growth. NanoString analysis showed the downregulation of genes encoding for extracellular matrix (ECM) components, such as collagens (COL1A1, COL3A1, COL4A1, COL5A1), fibronectin, laminins (LAMA3, LAMA4), and SLRP family proteins (LUM, BGN, DCN and FMOD); whereas genes involved in ECM degradation were dramatically upregulated (MMP1, MMP3 and MMP10). A protein antibody array technique was used to corroborate the NanoString MMP expression data. Ingenuity Pathway an alysis showed that TGF-Beta signaling network was significantly suppressed due to the Cd exposure, and the inhibited TGF-Beta signaling network have statistically strong associations with a heightened cell proliferation state. **Conclusion:** Due to prolonged Cd exposure, fibroid cells developed altered phenotypes in cell morphology, motility, proliferation, glycogen distribution, anchorage independent growth, and pathway signaling. **Impact statement:** Continuous chronic environmental Cd exposures may pose a cancer risk for women with uterine fibroids.

Cancer Therapy 1: Novel Therapies and Drug Delivery

P319/B326

Novel Combination Treatment Designed to Target Both Metastatic Cells and Proliferation in Pancreatic Ductal Adenocarcinoma.

M. Karl, G. Russo, B. Starich, H. Tan, T. Pan, D. Wirtz; Johns Hopkins University, Baltimore, MD.

Pancreatic cancer is the 4th most common cause of cancer-related deaths in the United States with only 7-9% 5-year survival rate. While there are a few combination treatments that have been shown to increase overall survival by several months, gemcitabine monotherapy, which has been used to treat

PDAC since 2006, is still the most commonly administered first-line treatment. Our objective is to improve patient survival by providing a novel combination therapy designed to inhibit the growth of solid tumors and prevent metastatic cancer cells from reaching secondary organs. Our lab has recently shown that secreted interleukin 6 (IL-6) and interleukin 8 (IL-8) can induce a migratory phenotype in tumorigenic, metastatic cancer cells in triple negative breast cancer models. Cells exposed to these cytokines display enhanced invasion through stromal environments, and this phenotype can be reversed by blocking the IL-6 and IL-8 receptors with the combined treatment of tocilizumab and reparixin. We hypothesized that this simultaneous blocking of IL-6 and IL-8 receptors would improve PDAC patient outcomes when used in combination with gemcitabine by targeting both proliferation and metastasis. Preliminary results show that this combination treatment has a positive effect in in vivo PDAC models. Our novel treatment combination was able to significantly reduce the tumor size, exceeding that seen from gemcitabine monotherapy. In addition, the triple combination reduced the metastatic burden and normalized the effect of the treatment among the mice in the group.

P320/B327

Identification of a Novel Compound That Targets Hepatocellular Carcinoma.

M. Maziveyi, M. Esparza, B. Fontoura, J. Shay; UTSW, Dallas, TX.

The death rates for hepatocellular carcinoma (HCC) are rising faster than the death rates of any other cancer in the United States. Our group has identified a unique intranuclear pathway for nuclear export of a subset of viral mRNAs and found that constituents of this pathway also regulate nuclear export of a subset of cellular mRNAs that encode regulators of tumor metastasis. Based on a high-throughput screen of 232,500 chemical compounds from our unique compound library, we have identified 22 small molecules that specifically inhibit this RNA export pathway without compromising bulk cellular mRNAs. One of the 22 compounds preferentially kills HCC cells with minimal toxic effects on normal liver cells. Our study shows that this compound reduces HCC cell growth, invasion and colony formation. In the future, we propose to test this compound in various mouse models, including human and patient derived xenografts introduced into immune suppressed mice. Finally, we will determine the genetic alterations that confer sensitivity or resistance to our compounds. Taken together, our studies may lead to the identification of a novel compound that specifically targets HCC, a cancer type that currently has no targeted therapies.

P321/B328

Investigating the Anti-proliferative Effects of a Derivative of Bitter Melon, Tubeimoside I, on Cancer Cells.

R. Villareal, S. Vetrone; Whittier College, Whittier, CA.

2019 Research Abstract Rachel Villareal **Investigating the Anti-Proliferative Effects of a Derivative of Bitter Melon, Tubeimoside I, on Cancer Cells** Although there have been advancements in treatments towards cancer, scientists have not yet found a cure. Current studies suggest some natural supplements can serve as alternative treatments for cancer, with the benefit of reduced to no side effects. *Momordica charantia* Linn, also known as Bitter melon, is a popular Asian herb used in traditional medicine to treat cholera, anemia, blood diseases, liver and spleen disorders, and diabetes. While, Bitter melon contains various active ingredients (terpenoids, sterols and fatty acids), Tubeimoside I (TBMS1) has been identified as exhibiting antitumor properties in two blood cancers, leukemia and lymphoma,

through the induction of cell cycle arrest and death. Our previous study investigated the cell viability, cytotoxicity, and caspase mediated apoptosis when the cancer cells were exposed to TBMS1. These results showed that both liquid (non-adherent cancer cells) and tumor forming (adherent cancer cells) cancer cell lines experienced a significant decrease in cell viability and increase in cytotoxicity when exposed to a minimum of 20 uM TBMS1. Therefore, this study explored the mechanism through which TBMS1 exerts its effects on these cancer cell lines. Possible mechanisms of death would be apoptosis, anoikis, autophagy, or necrosis for breast and prostate cancer cell lines. Briefly, MCF7, LNCap, and Jurkat cell lines were exposed to a 25 uM concentration of TBMS1 over a period of 48 hours and assessed for Necrosis and Apoptosis mechanisms. This analysis shows that the MCF7 cell line experienced apoptosis first and then secondary necrosis while the LNCap and Jurkat cell lines experienced necrosis as the primary manner of cell death.

P322/B329

Investigation of Novel Small Molecule Ferroptotic Compounds.

N. Kuganesan, S. Dlamini, J. McDaniel, R. A. Koranne, V. L. M. Tillekeratne, W. R. Taylor; University of Toledo, Toledo, OH.

Ferroptosis is a form of iron-dependent cell death characterized by elevated lipid peroxides and reactive oxygen species (ROS). We have identified a novel class of small molecules that induce ferroptosis in certain types of cancer cells. ROS is produced as a byproduct of metabolism in almost every cell. Glutathione (GSH) plays an essential role in scavenging ROS to maintain cell viability, and acts as a cofactor of Glutathione peroxidase 4 (GPX4) that protects lipids from oxidation. Cysteine, provided by uptake of extracellular Cystine, is essential for GSH synthesis. Ferroptosis occurs via two mechanisms: blocking the Cystine importing system Xc^- (Type I inducer) or inhibiting GPX4 activity (Type II inducer). System Xc^- is an antiporter transmembrane protein which imports Cystine and exports Glutamate. Our previous work indicated that our compound 6E decreased glutamate secretion as well as reduced thiols (measured using monochlorobimane; MCB) consistent with a type I mechanism. Here we show using FITC-conjugated cystine, that indeed, cystine import is reduced by 6E. We also investigate the specificity of our previous result with MCB. Since GSH is the most abundant reduced thiol in many mammalian cells, MCB is widely used as a marker of GSH. However, other thiols may contribute to results with this dye. Therefore, we transfected MDA-MB 231 cells with the biosensor Grx1-roGFP2 to measure the level of intracellular oxidized glutathione (GSSG). Grx1 uses glutathione to reduce roGFP2 altering its spectral properties. Proximity of Grx1 to roGFP2 provides a measure of glutathione in live cells. Upon treatment with 6E, we found a higher level of GSSG confirming our previous results with MCB. All these results together are consistent with our hypothesis that 6E kills via Type I mechanism. Even though ferroptosis is a well-established form of cell death, signaling pathways that modulate this process are not known. Therefore, we used a panel of growth factors/kinase inhibitors to test effects on 6E induced ferroptosis. We discovered that two chemically distinct inhibitors of IGF1 and insulin receptors could rescue from 6E mediated cell death. However, addition of excess IGF1 did not sensitize cells to ferroptosis. Either insulin signaling is maximal in our cell lines or our tyrosine kinase inhibitors block ferroptosis via alternative mechanisms. Ongoing research will address these questions.

P323/B330

3D Bioscaffolds from Bovine Bone Marrow: a Model for Testing New Drugs Targeting Hematopoietic Malignancies.

F. M. Roversi[1], M. L. P. Bueno[1], R. G. Rosa[1], J. E. R. Bianco[1], A. S. S. Duarte[1], A. Molinari[2], M. Botta[2], S. T. O. Saad[1]; [1]Hematology and Transfusion Medicine Center-University of Campinas/Hemocentro-UNICAMP, Campinas, São Paulo, BRAZIL, [2]Dipartimento di Biotecnologie, Chimica e Farmacia-Università degli Studi di Siena, Siena, ITALY.

Myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML) are hematopoietic malignant disorders with low chances of response to chemotherapy and high mortality rates. Furthermore, chemotherapy treatment adds considerable morbidity to the patients who are, frequently, older than 60 years. Thereby, advances in the understanding of molecular targets associated with their pathogenesis as well as the development of new drugs and testing strategies have been the subject of research over the past years. We have previously identified an overexpressed gene, *hematopoietic cell kinase* (HCK), in bone marrow hematopoietic stem cells (HSC) from MDS and AML patients, which activates the PI3K and MAPK pathways, increases cell growth and reduces apoptosis. We then produced a chemical inhibitor (iHCK), which showed selective efficacy for leukemic cells and did not affect normal HSC (Roversi *et al.* BBA Mol Basis Dis. 2017, 1863(2):450-61). In order to study the activity of this new pharmacological compound in MDS and AML cells in a more physiological environment, we developed a 3D bioscaffold by decellularization of bovine bone marrow that enables co-cultures and mimics the bone marrow niche (Bianco *et al.* Biomat Sci 2019, 7(4):1516-28). After informed written consent and approval of the Ethical Committee of University of Campinas (CAAE 1000.0.146.00-11), in accordance to the Helsinki Declaration, HSC were isolated from bone marrows of healthy donors (HD), MDS and AML patients and were treated or not with iHCK in liquid culture containing X-Vivo medium plus cytokines (SCF, IL-3, IL-6, TPO) for three days. Meanwhile, HS-5 mesenchymal cells were stirred for 3h before being cultured into 3D bioscaffolds with DMEM and fetal bovine serum. iHCK or vehicle (DMSO) treated HSC were introduced into 3D bioscaffold containing or not HS-5. 3D bioscaffold was evaluated after 7 and 14 days, by light microscopy (hematoxilin and eosin regular staining) and immunohistochemistry (expression of CD34 and CD90 antigens). Results showed that iHCK treatment reduced MDS and AML hematopoietic stem cells proliferation when compared to HD HSC in the 3D bioscaffold containing HS-5 cells and confirmed the crosstalk between hematopoietic and mesenchymal cells since normal or malignant HSC were preferentially located in areas containing HS-5 cells. Indeed, HSC cells have a very low growth in 3D bioscaffolds without HS-5 cells. In conclusion, selective HCK inhibition is a promising strategy for MDS and AML treatment and 3D bioscaffolds obtained from bovine bone marrow represent a potential platform for hematopoietic stem cells expansion and testing of new drugs.

P324/B331

Anti-proliferative and Apoptotic Inducing Activity of Novel *2-deoxy-d-glucobenzotriazoles* on Cancer Cells.

M. Turbi; Farmingdale State College, Farmingdale, NY.

A hallmark of cancer cells is characterized by an increase in glucose consumption and aerobic glycolysis. Cancer cells are known to rewire their metabolism to promote unregulated tumor proliferation and survival and meet high demands for energy. The alteration of metabolic pathways has become a target for developing strategies that exclusively affect cancer cells and not normal cells. In this study, we were

interested in developing chemical inhibitors that target glycolysis in cancer cells but minimally inhibit normal cell growth. Based on previous findings on the biological effects of benzotriazoles, a series of novel benzyl, acetyl and fully deprotected glycosylbenzotriazoles were chemically synthesized and screened for their anti-proliferative properties. Modifications were made to these agents based on the findings of our study and the analysis of various protecting groups and lipophilic nature of the compounds tested. Using HeLa cells, a cervical cancer cell line, we performed MTT (3-(4, 5-dimethylthiazolyl-2)-2, 5-diphenyltetrazolium bromide) cell viability assays 24 hours post-treatment at various concentrations of these compounds. We found that compounds OBn-162 and OAc-220 significantly decreased cell viability compared to DMSO-treated control cells. We next wanted to test the most effective compounds using a primary cell line. We used Human M2 macrophages that have been stimulated using M-CSF (macrophage colony stimulating factor) and found that the compounds tested may have a reduced cytotoxic effect on normal cells compared to HeLa cells. Finally, we found that cell viability and apoptosis synergistically increased when cells were treated with both OBn-162 and the apoptosis-inducing chemotherapeutic drug Paclitaxel simultaneously. Taken together, our studies provide evidence for potential use of these compounds and their derivatives as chemotherapeutic agents. However, more work must be done to determine the exact mechanism of these compounds and to determine their effects on other cancer and normal cell lines.

P325/B332

Characterization of a New Microtubule-depolymerizing Compound with Anti-cancer Properties.

K. Larocque, D. Jaunky, P. Liu, P. Forgione, A. Piekny; Concordia University, Montreal, QC, CANADA.

We synthesized a new family of compounds with anti-cancer properties. Microtubule-targeting agents are some of the most successful chemotherapies that are still in use. However, they can also affect healthy cells causing serious side effects, and patients often develop resistance to these drugs. Thus, there is a desire to increase the repertoire of anti-cancer drugs. We strategically designed a scaffold with several functional groups amenable to modifications for structure-activity-relationship studies. Importantly, the compounds were designed with properties ideal for in *vivo* use, and to probe molecular space, but without a specific target in mind. Of ~40 derivatives, we found that several have high efficacy in a myriad of cancer cells, while others have no or little effect, suggesting that efficacy can be attributed to changes in the functional groups and is not due to the scaffold. Our lead compound, C75, has IC_{50} for viability ranging from 100-200 nM in breast cancer cells, 300-400 nM in cervical, lung, colorectal cancer cells, 800 nM in fibroblasts in culture, and >1 uM in healthy fibroblasts from patients. We found similar efficacy in multi-cellular tumor spheroids (MCTS) derived from some of these cell lines. To determine C75's mechanism of action, we performed studies in cells and in *vitro*. Flow cytometry and imaging studies revealed that C75 arrests cells in mitosis. Staining cells for gamma-tubulin, centrin-2 and tubulin revealed that C75 preferentially affects spindle poles, which fragment forming multi-polar or disorganized spindles. To determine if C75 directly binds to tubulin, we performed in *vitro* binding and polymerization assays. C75 effectively blocked polymerization at concentrations lower than colchicine, a well-characterized compound known to disrupt polymerization. Competition assays revealed that C75 was able to compete with colchicine for tubulin-binding, similar to nocodazole. However, this competition was not sustained over time, suggesting that although C75 binding to tubulin could overlap with the colchicine site, it does so less efficiently. In addition, the spindle phenotypes caused by C75 in cells are different compared to colchicine, and they show synergistic phenotypes when combined. This data suggests that C75 has unique accessibility to microtubules, preferentially binds to a different site on

tubulin, and/or has an additional molecular target in cells. Thus, we have identified a new, modifiable tubulin-targeting compound with high selectivity towards breast cancer that warrants additional in *vivo* studies.

P326/B333

Sensitization of Multidrug Resistant Cancer Cells HCT-116 by Surface Modified PAMAM Dendrimer with Gallic Acid.

K. Priyadarshi; Institute of Advanced Research, Gandhinagar, INDIA.

Cancer treatment is restricted due to the resistance development in cancer cells by chemotherapeutic drugs. Resistance to chemotherapy is massive challenge in cancer therapeutics. Therefore, it is important to address this issue. Gallic acid (GA) is a natural plant compound that exhibits various biological properties including anti-proliferative, anti-inflammatory, anti-oxidant and anti-bacterial. Despite of the wide spectrum biological properties GA has cytotoxic response, low solubility and low bioavailability. To overcome this problem, GA was conjugated with the Polyamidoamine (PAMAM) dendrimer for improving the bioavailability and efficient delivery in drug resistant HCT-116 Colon Cancer cells. In our study we have modified surface of PAMAM dendrimer with Gallic acid and examine their anti-proliferative effects. Further, drug resistant colon cancer cells were established and thereafter treated with different concentration of PAMAM-GA to examine their anti-proliferative potential and underlying mechanisms of multidrug resistance in cancer cells. Our results show that PAMAM-GA conjugate induces apoptotic cell death in HCT-116 and drug-resistant cells examined by an nexin-PI staining and western blot of caspase-9 and caspase-3. In addition, it also shows that multidrug resistant drug transporter P-gp protein expression was down regulated with increasing the concentration of PAMAM-GA conjugate. After that we also observed the significant difference in Rh123 efflux and accumulation in drug sensitive and drug resistant cancer cells. Thus, our study suggests that conjugation of anti-cancer agents with PAMAM could improve drug resistant property and cytotoxic response to treatment of cancer. Keywords- P-gp, Drug resistance, Gallic acid, PAMAM dendrimer, Apoptosis

P327/B334

Modulating Ruthenium Induced Trafficking of Atp7b to Overcome Drug-resistance in Cancer.

***. Ruturaj**[1], K. Purkait[2], A. Mukherjee[2], A. Gupta[1]; [1]Department of Biological Sciences, Indian Institute of Science Education & Research Kolkata, Kolkata, INDIA, [2]Department of Chemical Sciences, Indian Institute of Science Education & Research Kolkata, Kolkata, INDIA.

The copper ATPase, ATP7B resides in Trans-Golgi Network (TGN) and provides copper to the secretory pathway. When copper level rises in cytosol ATP7B vesicularizes and traffics to the plasma membrane (PM) to excrete out excess copper. ATP7B has 6 Metal Binding Domains (MBDs) in cytosolic N-terminal that works as copper sensors. Due to its Cys residue (CXXC) in the MBDs, ATP7B also sequesters Platinum(Pt) based chemotherapeutic drugs and traffics to export it out. Ruthenium (Ru) based compounds due to their anticancer properties against resistant-cancer are potential therapeutic alternatives to Pt resistant cancers. We have investigated if Ru-complexes are also disposed to ATP7B based sequestration and export. Further, we have designed Ru-complexes that can bypass ATP7B sequestration and hence promises to serve as a better chemotherapeutic. We have developed a series of $Ru^{II}(\eta^6$-*p*-cymene) complexes that showed cytotoxicity against cancer cells. We found that unlike Cisplatin (CDDP), Ru complexes showed no change in the expression level of ATP7B, making it a

preferred choice over Pt-drugs. Trafficking of ATP7B from TGN to vesicles was used as a measure of drug export. We performed immunofluorescence in Ru compounds (**chloro**) treated HepG2 cells and found ATP7B to traffic. We confirmed the phenomena performing time-lapse fluorescence microscopy where trafficking of ATP7B was triggered in minutes of addition of the drug. But when the same was performed with Ru complex carrying a different ligand (**iodo**), we observed absence of ATP7B vesicularization from TGN. Immunostaining in HepG2 cells revealed that though vesicularization was absent, ATP7B exits TGN and shows tight perinuclear accumulation. Measurement of Ru concentration in cell revealed the iodo-Ru complex is exported less from the cell than its chloro counterpart. To establish sequestration of Ru by ATP7B, we used a previously established assay where *E.coli* form filaments upon CDDP treatment and are rescued by expressing N-Terminal of ATP7B (N-ATP7B) in the bacteria, suggesting drug sequestration. We were able to rescue *E.coli* cells from Ru toxicity by expression of N-ATP7B. But in the case of iodo-Ru we observed *E.coli* filamentation, suggesting no sequestration. Among the Ru-compounds tested, iodo-Ru shows least binding to GSH. Presently we are trying to understand the molecular mechanism of binding of Ru-complex with the purified N-terminus of ATP7B using Isothermal Titration calorimetric studies. ATP7B play a major role in resistant to Ru-based anti-cancer agents similar to CDDP. In this study, we have designed Ru-compounds that escape ATP7B sequestration and export, hence may be a better alternative to Pt drugs.

P328/B335

Taxane Resistance in Breast Cancer Controlled by the Apc Tumor Suppressor.

E. Astarita[1], C. Hoover[1], A. Wasierski[2], E. Cinquegrani[1], **J. R. Prosperi**[3]; [1]University of Notre Dame, South Bend, IN, [2]St. Joe High School, South Bend, IN, [3]Indiana University Sch Med-South Bend, South Bend, IN.

Adenomatous Polyposis Coli (APC) is a multi-domain tumor suppressor protein that binds to proteins including β-catenin, axin, and microtubules (MTs). APC is lost in many epithelial cancers and up to 70% of sporadic breast cancers, with a tendency towards triple negative breast cancers (TNBCs). Our laboratory previously demonstrated that APC knockdown in the human TNBC cell line, MDA-MB-157, resulted in resistance to the Taxane family chemotherapeutic agent, Paclitaxel (PTX). Given that PTX and APC both alter MT dynamics and impact the G2/M phase of the cell cycle, we sought to understand the molecular mechanisms of APC-mediated resistance. We **hypothesized** that genes involved in the G2/M transition would be altered in the absence of APC, leading to PTX resistance. We first performed an unbiased analysis of transcriptomic changes downstream of APC loss to identify potential therapeutic targets to overcome PTX resistance. In this, a cadre of transcripts involved in regulation of the cell cycle were identified, including AR, FOXS1, and GLI1. Upon validation of results by qRT-PCR and western blot, studies in the laboratory will investigate the effect of manipulating expression of these genes on the response to PTX. Upon further investigation into the cell cycle, we observed no change in the G2/M arrest induced by PTX. However, analysis of G2/M checkpoint proteins, CDK1 and cyclin B1, showed a significant increase in CDK1 expression in APC^{KD} cells compared to control. Nuclear fractionation demonstrated that nuclear CDK1 localization is increased after PTX treatment selectively in the APC shRNA cells. Based on these findings, we performed combination studies using a CDK1 inhibitor (RO-3306) with PTX treatment. PARP (total and cleaved) was used to measure apoptosis, and showed enhanced cleavage in the APC^{KD} cells specifically after combination treatment. Overall, our studies strive to understand the molecular nature of PTX resistance in APC^{KD} cells, and to identify therapeutic target(s) for APC-mutant TNBCs.

P329/B336

Decreased Expression of Eno-1 Promotes Cisplatin Resistance by Inducing Senescence and Altering Metabolic Pathways.

Y. Santana-Rivera[1,2], N. Grafals-Ruíz[1,2], B. I. Quiñones-Díaz[1,2], R. J. Rabelo-Fernández[3], G. S. Santiago-Sánchez[1,2], E. L. Lozada-Delgado[3], P. E. Vivas-Mejía[1,2]; [1]UPR - Science Medical Campus, San Juan, PR, [2]Comprehensive Cancer Center UPR, San Juan, PR, [3]UPR - Río Piedras Campus, San Juan, PR.

Ovarian Cancer is the fifth leading cause of death among women worldwide. It accounts for 23,000 deaths in the US alone. The standard treatment for this malignancy is surgical tumor removal in combination with platinum-based chemotherapy. Despite initial good response, patients develop resistance to platinum-based drugs which results in recurrence of the disease. Several mechanisms for platinum-resistance have been proposed, however the events leading up to resistance remain elusive. Therefore, it is imperative to study the molecular pathways leading to cisplatin resistance. Molecules in these pathways will be further used as therapeutic targets for platinum resistant ovarian cancer. Aimed to identify proteins associated with cisplatin resistance we performed proteomic studies in cisplatin sensitive (A2780) and cisplatin resistant (A2780CP20) ovarian cancer cells. One of the most dysregulated proteins in these cells was Enolase-1 (ENO1), an enzyme involved in the glycolytic pathway. ENO1 was found to be reduced in cisplatin resistant cells (A2780CIS, A2780CP20, OV-90CIS, OVCAR3CIS) as compared to their sensitive counterparts (A2780, OV-90, OVCAR3). We hypothesize that a way to acquire resistance is through senescence along with a reprograming of the metabolic pathways, using glycolysis as the main source of ATP, and mitochondrial respiration as an external source of energy. First, we evaluated the role of senescence by analyzing the levels of beta-galactosidase present in an Ovarian Cancer cell panel. We found that ovarian cancer resistant cell lines exhibit high levels of beta-galactosidase as compared to their sensitive counterpart indicating the presence of senescent cells. To further validate this results, we evaluated the levels of p21 in these cells. P21 is involved in cell cycle arrest, maintaining cell viability while leaving it in a senescent state. Furthermore, we analyzed intracellular glucose in the ovarian cancer cell panel and observed that cisplatin resistant cells have an increase in glucose accumulation as compared to their sensitive counterparts. We also measured the ATP levels and our preliminary results suggests higher ATP consumption in cisplatin resistant cells compared with their sensitive. Taking this into consideration, we performed clonogenicity assays under different nutrient conditions (glucose, glutamine, galactose, and pyruvate) in cisplatin resistant cells (A2780CP20). These results will help us to understand the molecular mechanism by which populations of ovarian cancer cells become more resistant to cisplatin treatment.

Anti-tropomyosin Drugs Prevent the Rescue of Vincristine-induced Mitotic Spindle Defects.

P. W. Gunning[1], Y. Wang[1], J. H. Stear[1], A. Swain[1], X. Xu[1], N. Bryce[1], I. B. Alieva[2], V. B. Dugina[2], T. Cripe[3], J. Stehn[1], E. C. Hardeman[1]; [1]University New South Wales, Sydney, AUSTRALIA, [2]Moscow State University, Moscow, RUSSIAN FEDERATION, [3]Nationwide Children's Hospital, Columbus, OH.

Drugs targeting a major component of the actin filaments of cancer cells, tropomyosin Tpm3.1, synergize with anti-microtubule drugs in neuroblastoma and lung cancer models both in *vitro* and in *vivo* and a wide range of other cancer types in *vitro*. We have determined the mechanism of synergy in HeLa cells to gain insight into the potential interaction of actin filaments and microtubules in the survival and proliferation of cancer cells. HeLa cells exhibit a strong synergistic response to the combined treatment

of vincristine (VCR) and anti-Tpm3.1 compounds, marked by an enhanced reduction in cell viability, apoptosis induction and mitotic cell cycle arrest. Tpm3.1 localizes to the cell cortex during mitosis, potentially associating with the microtubule network, particularly the dynein/dynactin complexes responsible for mediating cortical pulling forces during spindle assembly. VCR alone causes supernumerary NuMA organized acentrosomal microtubule organizing centers upon nuclear envelope breakdown, which can be resolved via a clustering mechanism to achieve bipolar cell division. The addition of anti-Tpm3.1 compounds inhibits NuMA-associated clustering in VCR-treated cells, leading to irreparable defects during spindle assembly and thus a largely increased number of cells with multi-polar spindles undergoing mitotic delay and catastrophe. We conclude that actin/Tpm3.1 filaments contribute to the formation of the bipolar spindle and play a critical role in the clustering of acentrosomal microtubule asters.

Quercetin Encapsulated Thermosensitive Liposome-gold Nanoparticles Depolymerize Microtubules, Suppress Hsp70 Expression and Induce DNA Damage in Cancer Cells After Photothermal Activation.

A. Pradhan, A. Kumari, R. Srivastava, D. Panda; Indian Institute of Technology Bombay, Mumbai, INDIA.

The overexpression of heat shock protein 70 (Hsp70) during photothermal therapy (PTT) leads to the development of thermotolerance in cancer cells. Quercetin (QE), a bioflavonoid has several targets such as Hsp70, tubulin, and phosphatidylinositol 3 kinase. QE is known to bind to tubulin and to inhibit tubulin polymerization. We hypothesize that by combining QE along with PTT will improve the therapeutic efficacy. Herein, we report QE encapsulated biodegradable thermosensitive liposome- gold (QE-LiposAu) nanoparticles for PTT of hepatocellular carcinoma. QE-LiposAu nanoparticles were prepared by in *situ* reduction of chloroauric acid using ascorbic acid in the presence of QE encapsulated thermosensitive liposomes. QE-LiposAu nanoparticles were characterized using electron microscopy, dynamic light scattering, and zeta potential measurements to confirm the gold coating on the liposomes. The four-fold increase in QE release at 45 °C with respect to 37 °C confirmed the thermosensitivity of DSPC: Chol (75:25 molar ratio) liposomes. QE-LiposAu nanoparticles were found to have a photothermal conversion efficiency ~ 75 % which makes QE-LiposAu nanoparticles an efficient photothermal agent. QE-LiposAu nanoparticles caused apoptosis mediated cell death upon 750 nm near infra-red laser (650 mW) treatment for 5 min. Further, we observed QE-LiposAu nanoparticles mediated PTT depolymerized microtubules, suppressed Hsp70 expression and induced DNA damage in hepatocellular carcinoma. Also, QE-LiposAu nanoparticles showed hemocompatibility, indicating its potential for in *vivo* application. The results indicated that these biodegradable and thermosensitive QE-LiposAu nanoparticles can be promising photothermal agents for cancer therapy.

Multifunctional Nanoparticles for Genetic Engineering and Bioimaging of Natural Killer (nk) Cells Therapeutics.

K. Kim, K. Park; CHA University, Seongnam-si, KOREA, REPUBLIC OF.

Recently, natural killer (NK)-based immunotherapy has attracted attention as a next-generation cell-based cancer treatment strategy due to its mild side effects and excellent therapeutic efficacy. Here, we describe multifunctional nanoparticles (MF-NPs) capable of genetically manipulating NK cells and tracking them in vivo through non-invasive magnetic resonance (MR) and fluorescence optical imaging.

The MF-NPs were synthesized with a core-shell structure by conjugation of a cationic polymer labeled with a near-infrared (NIR) fluorescent molecule, with the aid of a polydopamine (PDA) coating layer. When administered to NKs, the MF-NPs exhibited excellent cytocompatibility, efficiently delivered genetic materials into the immune cells, and induced target protein expression. In particular, the MF-NPs could induce the expression of EGFR targeting chimeric antigen receptors (EGFR-CARs) on the NK cell surface, which improved the cells' anti-cancer cytotoxic effect both in vitro and in vivo. Finally, when NK cells labeled with MF-NPs were injected into live mice, MF-NP-labeled NK cells could be successfully imaged using fluorescence and MR imaging devices. Our findings indicate that MF-NPs have great potential for application of NK cells, as well as other types of cell therapies involving genetic engineering and in vivomonitoring of cell trafficking.

Functionalization of Gold Nanoparticles by the *Clostridium Perfringens* Enterotoxin C-terminus *for* an Optical Induced Ablation of Tumor Cells.

A. Becker, **A. Ngezahayo**; Leibniz Universität Hannover, Department of Cell Physiology and Biophysics, Hannover, GERMANY.

Expression of claudins is increased in tumor cells. We proposed to conjugate the C-terminus of the *Clostridium perfringens* enterotoxin (C-CPE) to gold nanoparticles (AuNPs) to produce a C-CPE-AuNP complexes (C-CPE-AuNPs). By binding to claudins in cell membrane, the C-CPE moiety should allow to put the AuNPs in close vicinity of cells, allowing a subsequent specific cell killing by laser induced optoperforation. The human Caco-2, MCF-7 and OE-33 as well as the canine TiHoDMglCarc1305 were identified as tumor cells expressing claudin-3, -4 and -7. Functional analysis showed that the cells formed good transepithelial barrier which was characterized by a high electrical resistance (TEER) and was perturbed by application of recombinant produced C-CPE. The recombinant C-CPE was used to generate C-CPE-AuNPs, which allowed to specifically eliminate the cells expressing claudins using the gold nanoparticle mediated laser perforation (GNOME-LP) technique. The efficiency of cell killing was related to the C-CPE concentration used for the AuNP functionalization. The scanning velocity was varied from 5 mm/s to 40 mm/s and the laser fluence was varied between 0 mJ/cm^2 and 75 mJ/cm^2. The maximal efficiency (> 90%) was achieved when the AuNPs were functionalized using 20 µg/ml C-CPE, scanned at 5 mm/s using a laser fluence of 20-30 mJ/cm^2. In 3D matrigel culture system, the optical treatment in presence of C-CPE-AuNPs completely destroyed spheroid composed of Caco-2 cells and reduced OE-33 cells spheroid formation. At cellular level, the optical treatment of the cells that bound C-CPE-AuNPs were stained by annexin V and showed reduced mitochondria activity. However, an enhancement of caspase 3/7 activity in the cells was not found and DNA analysis did not show apoptosis related DNA ladder. The results gives the physical parameters for an optimal AuNP functionalization using C-CPE as well as optoperforation. Moreover the results suggest that the combination of C-CPE-AuNPs and optical treatment induced a massive cell permeabilization followed by necrosis related cell death.

Antibody Conjugated Nanoparticles Solid Lipid Nanoparticles as Drug Delivery Systems for Hydrophobic Pharmaceuticals in Cancer Therapy: Synthesis, Uptake, and Effect.

M. K. Notabi, E. C. Arnspang, M. Ø. Andersen; University of Southern Denmark, Odense, DENMARK.

Despise the progress in prevention, detection, and treatment of cancer, the disease remains at the second place in causes of death in the world. Currently, one of the main treatment methods includes the use of chemotherapeutic agents such as small molecule drugs. However, these small molecule drugs give rise to challenge that includes poor solubility, bioavailability, and absorption within the body and the destruction of normal cell tissue, toxicity, and the risk of development of drug resistance. In the last two decades, there has been an increased interest in nanoparticles both in terms of diagnostics and drug delivery for various diseases including cancer. The focus of this study is the development of a targeted drug delivery system for cancer therapy composed of solid lipid nanoparticles (SLNs). Antibody conjugated SLNs in the sub-500 nm range are synthesized for use as an actively targeted drug delivery system using a simple and inexpensive one-step synthesis of SLNs capable of encapsulating small molecule drugs. The SLNs consists of a lipid core which surface is conjugated to both an albumin stealth corona and targeting antibodies (anti-EGFR) and are designed to release the cargo by disassociating when entering the intracellular compartment. Using this one-step synthesis method, SLNs with diameter down to 89 nm and zeta potential of -29 mV was obtained. Cellular uptake of the SLNs loaded with the model drug Nile Red was examined in *vitro* in CAL27, HeLa, hMSC, and H1299, respectively. It was found that albumin coating stabilized the SLNs against aggregation in serum and reduced non-specific cell uptake. Furthermore, antibody conjugation of the stealth SLNs led to a marked cellular retargeting thus increasing the uptake of the model drug. Additionally, free-floating SLNs binding to the cell surface for subsequently being internalized within the time range of ~30 minutes to 2 hours have been visualized. Finally, the SLNs were tracked within the cells to determine their fate by observing colocalization with early and late endosomes as well as lysosomes where it was found that the SLNs are capable of endosomal escape and avoid lysosomal degradation. This SLNs system is simple to synthesize, have good serum stability and stealth properties and have the potential to be versatile targeted towards cancer cells using antibodies.

Copper Sulfide and Folate Nanoparticles and Photothermal Therapy: Novel Therapy for Gynecological Cancers?

E. C. Regisford, P. Plair, D. Varela-Ajche, A. Eze, A. Estrada-Martinez, D. Ramos, A. Balinger, A. Oki; Prairie View A&M University, Prairie View, TX.

The gynecological cancers, endometrial, ovarian and cervical cancer, affect over 30% of women nation-wide, with a combined mortality rate of over 10%. Endometrial cancer is the most common gynecological cancer, but ovarian cancer is the deadliest. The incidence of cervical cancer has decreased significantly over the years due to Pap tests, but its mortality rates are still too high, if the disease is not detected in the early stages. While treatments of surgery, chemotherapy and radiotherapy have been successfully used to treat gynecological cancers, there is still a relatively high incidence of relapse. Hence, the development of novel therapeutic approaches such as, photothermal therapy (PTT) used in combination with nanoparticles, that would decrease the incidence of relapse and detrimental treatment side effects, is of utmost importance. Recent studies have indicated that the increase in

temperature during PTT could kill targeted cancer cells, but normal cells could also be damaged by heat conduction. It has also been determined that if a cell is targeted by engulfing a nanoparticle, such as Folate/Folic acid (FA), then cancer cells that express FA receptors will absorb FA and be greatly affected during PTT. Therefore, the objective of this project was to determine the effect(s) of PTT, using copper sulfide (CuS) and folic acid (FA) nanoparticles, on endometrial (RL95-2); ovarian (SKOV-3) and cervical (HeLa) cancer cell lines. We hypothesized that the aforementioned cells treated with a CuS-FA nanocomposite, then subjected to PTT will be less viable than control cells. To test this hypothesis, cultured RL95-2, SKOV-3 and HeLa cells, and A549 cells (a lung cancer cell line that is FA receptor-negative) were treated with the following combination of nanoparticles: (1) 250ng of CuS; (2) 250ng FA; (3) 250ng of CuS-FA nanocomposites and (4) 0ng (control); for a period of 48 hours. All cells were then exposed to PTT at the near infrared region (900 nm wavelength) for 10 minutes, then subjected to an MTT assay to determine cell viability. Relative to control (0ng) cells, there was a significant decrease in viability in the RL95-2, SKOV-3 and HeLa cells treated with the CuS-FA nanocomposite and PTT. The decrease in viability was highest in HeLa cells, followed by SKOV-3 cells then RL95-2 cells, then A549 cells. This observation could be attributed to the presence of FA receptors being highest on HeLa cells, followed by SKOV-3 cells. Further studies of PTT/CuS nanoparticles and their effects on the TGF-β gene and gene products in the RL95-2, SKOV-3 and HeLa cells, would provide data that could improve therapy for gynecologic cancers.

Pluronic Micelles Encapsulated Curcumin Potentiates Apoptosis and Anti-inflammatory Response in Drug Resistant Human Breast Adenocarcinoma Cells.

F. U. Vaidya, C. Pathak; Indian Institute of Advanced Research, Gandhinagar, INDIA.

Chemotherapy is the most common treatment for cancer. But after some time cancer cells acquire resistance against chemotherapeutic drugs. Therefore, multidrug resistance is one of the serious concerns in the failure of anti-cancer therapies and alternative therapy is the need of the hour. Natural flavonoids may be the better alternatives of chemotherapeutic agents since few decades but poor bioavailability of many drug candidates is one of their limitations. Curcumin is the natural polyphenolic compound derived from rhizome of the plant *Curcuma longa* which is a well known chemopreventive and therapeutic agent. However, the pharmacological application of curcumin is obstructed due to low bioavailibility and rapid systemic elimination. In the present study, we have synthesized aqueous soluble Pluronic Micelles encapsulated Curcumin (PMsCur) to combat drug resistance in cancer cells. Pluronics are biological response modifiers and display an ability to interact with hydrophobic surfaces and biological membranes. In this regards, we have established drug resistant human breast adenocarcinoma cells (MCF-7/R) and analyzed biological activities of PMsCur. Our studies revealed that PMsCur downregulates P-glycoprotein which is a drug efflux transporter linked with multiple drug resistance and CD44v6 which is a cancer stem cell marker. Cytotoxicity studies suggest that PMsCur efficiently inhibits the proliferation of MCF-7/R cells as compared to free curcumin. Further, we explored the mechanism of cell death and found that PMsCur exhibits apoptosis by mitochondrial disruption and activation of effector caspases in MCF-7/R cells. Moreover, the inflammatory study revealed that PMsCur inhibits NF-kB activity and downregulates proinflammatory cytokines. Interestingly, PMsCur modulates the expression of redox regulating enzymes NADPH oxidases (NOXs) and downregulates nuclear factor E2-related factor-2 (Nrf-2) which is associated with multiple drug resistance in cancer. Further, we found that PMsCur inhibits Epithelial to Mesenchymal transition and attenuates invasive

capabilities of MCF-7/R cells. Interestingly, PMsCur was nontoxic to normal cells. Taken together, this study suggests that PMsCur drastically sensitize drug resistant MCF-7 cells and enhance therapeutic potential of curcumin with a safety profile, which may offer a new stratagem for improving drug delivery in cancer therapy.

The Antimalarial Drug Pyronaridine Interacts with DNA, Inhibits Topoisomerase II, and Is a Good Candidate for a Repurposed Anticancer Drug.

P. Villanueva; University of Texas at El Paso, El Paso, TX.

Based on our previous work, the antimalarial drug pyronaridine (PND) was shown to exert anticancer activity. PND induces apoptosis by means of mitochondrial depolarization, alteration of cell cycle progression, and DNA intercalation. We have further investigated the mode of action of PND and have determined that it acts as a topoisomerase II inhibitor. In addition, preliminary *in-vivo* studies suggest that PND hinders tumor progression. In vitro combination studies of PND with known anticancer drugs such as Cisplatin and Gemcitabine, show that the combined effect of these drugs with PND have greater cytotoxic activity against cancer cells than individual administration. This results lead to the possibility of future *in- vivo* combination experiments. The findings presented in this study reconfirm and give a positive outlook to PND's potential as an anticancer drug.

P338/B345

Application of Anticancer Drug Screening System Using Silica Fiber-based Three-dimensional Culture Scaffold.

Y. Komizu[1], N. Sakata[1], S. Chitose[1], T. Iwasa[2], K. Sasaki[2], R. Kojima[2], M. Kawabe[2], T. Matsushita[1]; [1]Dept. Of Applied Life Science, Sojo University, Kumamoto, JAPAN, [2]Central Research Laboratory, Japan Vilene Company, Ltd., Ibaraki, JAPAN.

[Purpose] Intrinsic or acquired multidrug resistance (MDR) in cancer cells is one of the major obstacles in the chemotherapeutic treatment of solid tumors. It is important to develop a cell-based in *vitro* system for testing anti-cancer drugs that can reflect the in *vivo* MDR characteristics of cancer cells. In this study, we examined the phenomenon of doxorubicin (DOX) resistance in human hepatoma (HepG2) cells by using the silica fiber-based three-dimensional (3D) culture scaffold (Cellbed) and compared the half maximal inhibitory concentration (IC_{50}) of DOX in 3D Cellbed culture with that of a monolayer culture. Furthermore, we examined DOX efflux in the 3D Cellbed culture. [Methods] After seven days of cultivation in the monolayer and 3D Cellbed cultures, the cells were exposed to DOX for two days. IC_{50} was measured by WST-8 assay with or without cyclosporin a (CsA), which is used to overcome drug resistance. Then we examined DOX efflux in the 3D Cellbed culture. After pre-incubation of the cells with 50 µM DOX at 37°C for 1 h, efflux was measured over time in the presence or absence of CsA. [Results and Discussion] the IC_{50} of DOX without CsA was significantly higher in the 3D Cellbed culture compared with that in the monolayer culture of HepG2 cells. However, the IC_{50} of DOX with CsA decreased to almost the same value in both the 3D Cellbed and monolayer cultures. These results suggest that the drug resistance phenomena of human hepatoma cells were expressed using the 3D Cellbed culture in *vitro*. We next examined the effects of CsA on DOX efflux from HepG2 cells in the 3D Cellbed culture. After 60 min, DOX efflux was markedly inhibited by CsA. This result suggests that reduction of the DOX IC_{50} in Cellbed culture by CsA reflects CsA-mediated inhibition of multidrug

resistance protein 1 (MDR1) activity. [Conclusion] the 3D Cellbed culture seems to provide a promising cell-based in *vitro* assay system for screening agents that may overcome the drug resistance of hepatic cancer cells.

P339/B346

Navitoclax Dramatically Enhances Death of Cells Arrested in Mitosis by Various Microtubule Inhibitors.

M. Suleimenov[1,2], S. Bekbayev[1,2], Y. Tagay[1], S. Kauanova[3], D. Potashnikova[4], **I. A. Vorobyev**[1,2,5]; [1]School of Science and Humanities, Nazarbayev University, Nur-Sultan, KAZAKHSTAN, [2]National Laboratory Astana, Nur-Sultan, KAZAKHSTAN, [3]School of Engineering and Digital Sciences, Nazarbayev University, Nur-Sultan, KAZAKHSTAN, [4]Biological Faculty, M.V. Lomonosov Moscow State University, Moscow, RUSSIAN FEDERATION, [5]A.N. Belozersky Institute and Biological Faculty, M.V. Lomonosov Moscow State University, Moscow, RUSSIAN FEDERATION.

Mitotic arrest induced by different microtubule inhibitors often results in the mitotic slippage with cell survival. This is the major limitation for the anti-cancer drugs based on the mitotic arrest. We analyzed the dose-dependent effect of microtubule inhibitors by time-lapse microscopy using two normal and six human cancer cell lines. Duration of mitotic arrest is almost independent from the drug concentration above the certain threshold, i.e. when no cell is able to undergo bi-polar or multi-polar division. On average it is in the range of 5-15 hours depending on the drug and cell type, and cells frequently undergo mitotic slippage. Slippage frequency remains relatively large even for high (μM) concentrations of Nocodazole, Vinorelbine and Paclitaxel. For each cell line examined the duration of mitotic arrest was the same for cells either dying in mitotic stage or undergoing mitotic slippage. Death of cells during mitotic arrest occurred through standard apoptotic pathway and activation of executive caspases 3/7 was rapid similarly to the Staurosporine-induced apoptosis. Cells had survived after mitotic slippage for more than 40 hours had long life expectancy. In attempt to minimize survival of cells arrested in mitosis we used Navitoclax (inhibitor of Bcl-2 proteins) together with microtubule inhibitors. Navitoclax at the concentrations of 0.3-1 μM was not toxic when applied alone, however induced apoptosis of cells after treatment with microtubule inhibitors. Combined treatment with microtubule inhibitors at concentrations inducing prolonged mitotic arrest and Navitoclax (300 nM) results in death of all cells had entered mitosis whenever they were unable to enter anaphase within 8-10 hours. Whereas, when cells undergo anaphase (though often abnormal one) in shorter time (4±2 hours), effect of Navitoclax diminishes. Flow cytometry analysis confirmed that accumulation of the G2/M population that happens after treatment with microtubule inhibitors in the concentration inducing prolonged mitotic blockade was diminished by addition of Navitoclax simultaneously with the increase of percentage of apoptotic cells. We suggest that inhibition of bcl-2 proteins makes mitotic cells more susceptible for apoptosis when cells are unable to switch from mitotic stage into interphase for a prolonged period of time. We conclude that Navitoclax is a potent inhibitor of mitotic slippage. This work was supported by Grant # AP05134232 from MES of the Republic of Kazakhstan.

MicroRNA-18a Targets MMP-3 in Platinum-resistant Ovarian Cancer.

B. I. Quiñones-Díaz[1], V. R. Sánchez-Guzmán[2], J. M. Reyes-González[1], P. E. Vivas-Mejía[1]; [1]University of Puerto Rico - Medical Sciences Campus, San Juan, PUERTO RICO, [2]University of Puerto Rico - Río Piedras, San Juan, PUERTO RICO.

Ovarian cancer is the deadliest gynecological malignancy in the United States accounting for around 14 thousand deaths annually. Currently, platinum-based therapies remain as the standard treatment for ovarian cancer patients. However, a significant number of women become resistant to cisplatin treatment. Although several mechanisms of cisplatin resistance have been confirmed, therapies targeting these pathways have not been clinically effective. MicroRNAs (miRNAs) are key regulators of gene expression at the post-transcriptional and play a key role in ovarian cancer progression and drug resistance. To identify novel target miRNAs that may be involved in platinum resistance we performed a miRNA expression array between cisplatin-resistant and cisplatin-sensitive ovarian cancer cell lines. In this preliminary study, we found that miR-18a-5p (miR-18a) was downregulated in cisplatin-resistant ovarian cancer cells compared to the sensitive parental cells. Furthermore, the use of miR-18a oligonucleotide mimics (miR-18a-OMM) showed therapeutic potential in cisplatin-resistant ovarian cancer cells*. To* further evaluate the role of mir-18a in the cisplatin resistance of ovarian cancer we sought to identify the miR-18a potential target genes. We performed a bioinformatic analysis using miRNA target prediction programs and expression profiles of ovarian cancer cells. The experimental validation was conducted by qPCR, Western Blot and luciferase reporter assays. By qPCR we observed downregulation of seven potential target mRNAs upon miR-18a-OMM transfection compared to control-OMM transfected cells. However, at the protein level, we only observed downregulation in MMP-3 (Stromelysin-1). In addition, we validated the direct interaction of miR-18a with the 3'UTR of MMP-3 by luciferase reporter assay. We also observed that MMP-3 was significantly increased in cisplatin-resistant ovarian cancer cells compared to their sensitive counterparts, the opposite expression trend observed for miR-18a. These results demonstrate that MMP-3 is a direct target of miR-18a in cisplatin-resistant ovarian cancer.

P341/B348

Potential Cancer Therapy by the Development of a Protein-based Drug Delivery System Nanoparticles Using Plant-derived Triterpenoids as Drugs.

Z. Torres[1], K. Griebenow[1], Y. Delgado[2]; [1]University of Puerto Rico, Rio Piedras, PR, [2]San Juan Bautista School of Medicine, Caguas, PR.

Nano-formulations for cancer therapy have become a strategy to minimize the lack of drug inactivation after administration into patients. An alternative to increasing the effectiveness of drugs is by the development of nanoparticles as drug delivery systems. Consequently, protein-based nanoparticles have been studied due to their potential to simultaneously increase the drug solubility and biological targetability for cancer therapy. Within the compound with solubility difficulty are the triterpenoids, which have shown anticancer activity against cancer. Herein, we developed spherical protein-based nanoparticles (diameter size 160-250 nm and polydispersity index value from 0.13) by use of a micro-emulsion method. Our nanoparticles sizes are compatible with tumor accumulation through the irregular vasculature observed in cancer tissues. Our system demonstrated toxicity in a cancer cell line, after incubation for 24h.

P342/B349

Down Regulation of Abc Transporters by the Erythropoietin Treatment Accelerates the Affect of Anti-cancer Reagents.

H. Matsui, H. Kurokawa; University of Tsukuba, Tsukuba, JAPAN.

Erythropoietin (EPO) is a glycoprotein cytokine which stimulates red blood cell production (erythropoiesis) in the bone marrow. The receptor of it (EPOR) was reported to exist on the cancer cellular membrane: more than 85% cancer cell expresses EPOR. Several reports suggested to play an important role for cancer cellular growth, however, the role of EPOR in cancer cells is not confirmed. The authors have studied the cancer cellular porphyrin accumulation, metabolism and excretion to clear the pathogenetic mechanism which involved the high concentration of porphyrins. The authors found that reactive oxygen species (ROS) accelerate both the cancer cellular porphyrin accumulation and the effect of photodynamic therapy. However, we cannot confirm which substrate is a key of signal transduction. EPO has been known used to be up-regulated at the metabolic acidosis via the stabilization of HIF-1α, a nuclear factor. Since HIF-1α can be stabilized by not only acidosis but also the high concentration of nitric oxide (NO), NO rich cancer cells may involve EPOR. Moreover, the purpose of EPO-EPOR system is likely to survive the hypoxic condition, it may keep intracellular heme/ porphyrins. The authors' hypothesis is EPO-EPOR system in cancer cells may down-regulate ABCG2 which excretes heme/ porphyrins, and several anti-cancer drugs. Moreover, if so, the excretion of several anti-cancer chemo reagents should be inhibited to involve more effective chemotherapy. Methods: to prove these possibilities, the authors carry out following experiments with gastric and colorectal cancer cells. The existence of EPOR, the amount of ABC transporters (B1, C5, G2) after the recombinant EPO (rEPO) exposure (dose dependency and time dependency) were analyzed by western blotting. Cytotoxicity of anti-cancer drugs with or without rEPO was measured with the Cell Counting Kit-8. Result: (1) EPOR existed in each cell line used in this study. (2) rEPO treatment involved down regulation of ABC transporters (B1, C5, G2) in dose dependently. (3) ABCG2 expression decreased until 24 hours after rEPO treatment. However, its expression re-increased 48 hours after treatment. (4) the 24 hours pretreatment of EPO significantly increased the effect of doxorubicin, paclitaxel, irrinotecan, cisplatin, 5-FU and oxaliplatin even in chemo-resistant cells. Conclusions: rEPO accelerates the effect of anti-cancer drugs via the down regulation of ABC transporters.

P343/B350

Lopinavir and Curcumin Directly Alters Bax/bcl2 and Vegf165b Mrna Levels to Suppress Human Squamous Cervical Carcinoma Cell Growth.

A. G. Adefolaju[1], A. Mwakikunga, 0699[2]; [1]University of Limpopo, Pietersburg, SOUTH AFRICA, [2]University of Malawi, Blantyre, MALAWI.

Following the success of the highly active antiretroviral therapy, the potential of a multidrug combination regimen for the management of cancer is intensely researched. The anticancer effects of curcumin on some human cell lines have been documented. Lopinavir is an FDA approved protease inhibitor with known apoptotic activities. Dysregulated apoptosis is important for the initiation of cancer while angiogenesis is required for cancer growth and development, this study, therefore, investigated the effects of the combination of lopinavir and curcumin on cell viability, apoptosis and the mRNA expression levels of key apoptotic and angiogenic genes; BAX,BCL2 and VEGF165b in two human cervical

cell lines; human squamous cell carcinoma cells - uterine cervix (HCS-2) and transformed normal human cervical cells (NCE16IIA). The two human cervical cell lines were treated with physiologically relevant concentrations ofthe agents for 120 h following which BAX, BCL2, and VEGF165b mRNA expression were determined by Real-Time qPCR. The Acridine Orange staining for the morphological evaluation of apoptotic cells was also performed. The combination of lopinavir andcurcumin up-regulated pro-apoptotic BAX and antiangiogenic VEGF165b but down-regulated the mRNA levels of anti-apoptotic BCL2mRNA in the human squamous cell carcinoma (HCS-2) cells only. The fold changes were statistically significant. Micrographs from Acridine Orange staining showed characteristic evidence of apoptosis in the human squamous cell carcinoma (HCS-2) cells only. The findings reported here suggest that the combination of curcumin and the FDA approved drug-lopinavir modulate the apoptotic and angiogenic pathway towards the inhibition of cervical cancer.

P344/B351

The Anti-proliferative Effect of the Newly Hybrid Compound against Human Cervical Cancer Involves Apoptosis Mediated by Stat3 Inactivation.

K. Chung[1], K. Lee[1,2]; [1]Department of Pharmaceutical Biochemistry, College of Pharmacy, Kyung Hee University, Seoul, KOREA, REPUBLIC OF, [2]Department of Life and Nanopharmaceutical Sciences, Graduate School, Kyung Hee University, Seoul, KOREA, REPUBLIC OF.

We previously reported the potential anti-proliferative activity of 3-(5,6,7-trimethoxy-4-oxo-4H-chromen-2-yl)-N-(3,4,5-trimethoxyphenyl)benzamide (TMS-TMF-4f) against human cancer cells; however, the underlying molecular mechanisms have not been investigated. In the present study, TMS-TMF-4f showed the highest cytotoxicity in human cervical cancer cells (HeLa and CaSki) and low cytotoxicity in normal ovarian epithelial cells. An nexin V-FITC and propidium iodide (PI) double staining revealed that TMS-TMF-4f-induced cytotoxicity was caused by the induction of apoptosis in both HeLa and CaSki cervical cancer cells. The compound TMS-TMF-4f enhanced the activation of caspase-3, caspase-8, and caspase-9 and regulated Bcl-2 family proteins, which led to mitochondrial membrane potential (MMP) loss and resulted in the release of cytochrome *c* and Smac/DIABLO into the cytosol. Also, TMS-TMF-4f suppressed both constitutive and IL-6-inducible levels of phosphorylated STAT3 (p-STAT3) and associated proteins such as Mcl-1, cyclin D1, survivin, and c-Myc in both cervical cancer cells. STAT-3 overexpression completely ameliorated TMS-TMF-4f-induced apoptotic cell death and PARP cleavage. Docking analysis revealed that TMS-TMF-4f could bind to unphosphorylated STAT3 and inhibit its interconversion to the activated form. Notably, intraperitoneal administration of TMS-TMF-4f (5, 10, or 20 mg/kg) decreased tumor growth in a xenograft cervical cancer mouse model demonstrated by the increase in TUNEL staining and PARP cleavage and the reduction in p-STAT3, Mcl-1, cyclin D1, survivin, and c-Myc expression levels in tumor tissues. Taken together, our results suggest that TMS-TMF-4f may potentially inhibit human cervical tumor growth through the induction of apoptosis via STAT3 suppression. This research was supposed by Basic Science Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education (NRF-2017R1D1A1B04030534).

Investigation of New Podophyllotoxin Derivatives as Anti-cancer Drug.

J. Kim[1], A. Kang[1], Y. Yoo[2], H. Um[1], **J. Park**[1]; [1]KIRAMS, SEOUL, KOREA, REPUBLIC OF, [2]KOREA UNIVERSITY, SEOUL, KOREA, REPUBLIC OF.

We previously reported that podophyllotoxin acetate (PA) inhibits the growth and proliferation of non-small cell lung cancer (NSCLC) cells and also makes them more sensitive to radiation and chemotherapeutic agents. In an attempt to enhance PA activity, we synthesized 34 derivatives based on podophyllotoxin (PPT). Screening of the derivative compounds for anti-cancer activity against NSCLC led to the identification of β-apopicropodophyllin (APP) as a strong anti-cancer agent. In addition to its role as an immunosuppressive regulator of the T-cell mediated immune response, the compound additionally showed anti-cancer activity against A549, NCI-H1299 and NCI-460 cell lines with IC50 values of 16.9, 13.1 and 17.1 nM, respectively. The intracellular mechanisms underlying the effects of APP were additionally examined. APP treatment caused disruption of microtubule polymerization and DNA damage, which led to cell cycle arrest, as evident from accumulation of phospho-CHK2, p21, and phospho-Cdc2. Moreover, APP stimulated the pro-apoptotic ER stress signaling pathway, indicated by elevated levels of BiP, phospho-PERK, phospho-eIF2α, CHOP and ATF4. We further observed activation of caspase-3, -8 and -9, providing evidence that both intrinsic and extrinsic apoptotic pathways were triggered. In vivo, APP inhibited tumor growth of NSCLC xenografts in nude mice by promoting apoptosis. Our results collectively support a novel role of APP as an anticancer agent that evokes apoptosis by inducing microtubule disruption, DNA damage, cell cycle arrest and ER stress.

Translational Profiling of UBQLN2 Mouse Models of ALS/FTD Reveals Novel Insight into Disease Progression.

M. D. Tatman, M. Hall, S. A. Ament, M. J. Monteiro; University of Maryland-Baltimore, Baltimore, MD.

Amyotrophic lateral sclerosis (ALS) is a fatal, neurological disease characterized by the progressive degeneration and subsequent death of both upper and lower motor neurons. Neuronal-specific expression of ALS/FTD-linked P497S Ubiquilin 2 (UBQLN2) mutation generates disease pathology in mice, which mimics the familial human disease. Traditionally, glial cells - including astrocytes - are known static supporters of neurons in the CNS. More recently, astrocytes have been implicated as integral components of nervous system networks and have been shown to proliferate disease progression. Here, we used translating ribosomal affinity purification (TRAP) to isolate motor neuron and astrocyte cell-type-specific mRNA from brain and spinal cord of 14 and 21 week old mice. Through translational profiling and high-throughput mRNA sequencing, age-related transcription level changes in astrocytes and motor neurons have been identified. Despite neuron-specific expression of the mutant P497S UBQLN2 protein, initial observations using Ingenuity Pathway an alysis (IPA) indicate significant changes in astrocytes - most notably the inhibition of oxidative phosphorylation. Thus, neuron-specific P497S UBQLN2 mutation initiates significant disruption in astrocytes, indicating that they may play significant role in pathogenesis. Comparison analyses between translatome and proteome data has provided novel insight that should enable us to discover drivers of disease progression.

A Role of Physical Properties of DNA in the Transcription of Non-coding RNA.

K. Uemura[1], O. Miura[2], T. Ohyama[1]; [1]Dept. Biol., Waseda University, Tokyo, JAPAN, [2]Res. Inst. For Sci. An d Eng., Waseda University, Tokyo, JAPAN.

We previously reported that a highly distinctive mechanical property resides in the majority of human pol II promoters and it plays a central role in the promoter function (Fukue *et al*.,*Nucl. Acids Res*., 2004, 2005). In the last decade, promoter databases were remarkably upgraded. Thus, we recently performed a follow-up study using both coding and non-coding RNA promoters. First, we classified the target regions (-200 to +200 relative to the TSS) into two groups: those carrying a core promoter element such as TATA-box, Inr, DPE, etc. An d those without any such element ("core-less promoters"). The former group was further divided into subgroups according to the element species. Second, the average flexibility profile was calculated for each group. Regarding the pol. II promoters, our original finding was confirmed. However, for the core-less non-coding RNA promoters, their average flexibility profile was somewhat different from that of the corresponding pol. II promoters: although the profiles around the TSS were similar with each other, ~+30 region also showed a distinctive flexibility profile in the case of core-less non-coding RNA promoters.To scrutinize the data, we further performed clustering with unsupervised machine learning. As the result, the core-less group was found divided into four clusters each with their own flexibility profile. Interestingly, it was also clarified that the average promoter strengths are considerably different among the four. Furthermore, the properties such as duplex disruption energy and protein-induced deformability were also found different among them. These results suggest that physical properties of DNA also play a key role in the function of the core-less non-coding RNA promoters and determine their relative strengths.

P348/B356

Colocalization of Cruciform Motifs and the Mammalian Poly(A) Signals.

O. Miura[1], T. Ohyama[2]; [1]Res. Inst. For Sci. An d Eng., Waseda University, Tokyo, JAPAN, [2]Dept. Biol., Waseda University, Tokyo, JAPAN.

Genomic DNAs have a large number of inverted repeat (IR) sequences. However, their function, if any, still remains elusive. Recently, we reported that IRs with cruciform-forming potential (referred to as 'CFIRs') are actively placed in the termination region of transcription in the *Escherichia coli* and *Saccharomyces cerevisiae* genomes (Miura *et al.*, *Curr. Genet.*, 2018, 2019). Furthermore, we also reported that there is a strong structural correlation between CFIRs and poly(A) signals of *S. cerevisiae* and the CFIRs generally exclude nucleosomes from the regions (Miura *et al.*, *Curr. Genet.*, 2019). In the current study, using the genomes of mouse and humans, we performed genome-wide analyses for the distribution, occurrence frequency and sequence characteristics for CFIRs. We found that A-tract- or T-tract-rich CFIRs were highly enriched on and around the poly(A) sites in both cases. Interestingly, the distribution profiles of CFIRs were somewhat similar among *E. coli*, *S. cerevisiae*, mouse and humans, suggesting their common role in the transcription termination. Furthermore, a strong structural correlation was found between the CFIRs and the poly(A) signals of mouse and humans. We also examined the relationship between CFIRs and chromatin structure in mouse. It suggested that the majority of the CFIRs occurring on and around the poly(A) sites is incorporated into nucleosomes and determines rotational setting of DNA, which is different from the case of the yeast. In this meeting, we will discuss what the colocalization of the cruciform motif and the poly(A) signal suggests.

P349/B357

Role of Curi Complex in Regulation of Mtorc1 Target Genes under Stress and Starvation.

S. Kumar, P. Balamurugan, A. Grove; Louisiana State University, Baton Rouge, LA.

Ribosome biogenesis is an expensive process involving expression of ribosomal protein genes and ribosomal RNA, consuming up to 90% of a cell's energy. Thus, this serves as a premier biological process to be targeted in emergencies such as stress and starvation to save energy. In yeast, Hmo1p (a high mobility group protein) along with other proteins binds Ribosomal Biogenesis (RiBi) genes and RNA Pol I transcribed genes. Besides RiBi-genes, Hmo1p also binds its own promoter. Interestingly, expression of *HMO1* is suppressed in response to mTORC1 (target of rapamycin complex) inhibition by rapamycin. Inhibiting mTORC1 causes the transcription factor Ifhl1p to leave the *HMO1* promoter. Ifhl1p moves to the nucleolus and forms another complex with Utp22p, CK2p and Rrp7p, a complex named as CURI. This complex formation seems to have a synergistic function in decreasing Ribosomal Biogenesis because Utp22p and Rrp7p are also involved in pre-ribosomal RNA processing when Ifhl1 is absent from the nucleolus. We report here that rapamycin treatment also decreases expression of *UTP22 and RRP7* up to five-fold. Since Ifhl1p gets replaced by the repressor Crf1p at the *HMO1* promoter during nutritional stress, we conducted a ChIP-assay at the *UTP22* and *RRP7* genes. Preliminary data from ChIP-assay suggests inactivation of *UTP22 and RRP7* gene expression by a mechanism similar to *HMO1* suppression; we detected replacement of Ifhl1p by Crf1p at the *UTP22* and *RRP7* promoters after 15 minutes. While reduced *HMO1* expression in response to rapamycin requires Tor1p, deletion of *TOR1* did not markedly affect expression of *UTP22* or *RRP7* on addition of rapamycin. We therefore propose that Tor2p can substitute for Tor1p in mTORC1 for regulation of *UTP22 and RRP7*, but not for regulation of *HMO1*.

P350/B358

Alternate Approaches to Understand Regulatory Mechanisms behind the Expression of a Sodium Calcium Potassium Exchanger in *Caenorhabditis Elegans*.

R. W. Motaher, D. O'Halloran; the George Washington University, Washington DC, DC.

Neurons utilize Na^+ and Ca^{2+} ions to regulate excitability. Defects in exchange can lead to a variety of health problems, such as epilepsy, which is characterized by an onset of spontaneous, recurrent seizures, arising from a loss in the balance of excitatory and inhibitory nerve impulses. One of the primary mechanisms by which cells maintain balanced levels of these $Na^{+\text{ and }}Ca^{2+}$ ions is by utilizing Na^+/Ca^{2+} Exchangers (NCX). Very little is known about the regulation of *ncx* genes, of which the *nckx* sub-family remains particularly under-studied. To learn more about the transcriptional regulation of this gene family, I study an *nckx* expressed in *C. elegans* named NCX-5. *ncx-5* expression is limited to a specific circuit of six sensory neurons. All six neurons are gas sensing the goal of my research is to understand why *ncx-5* expression is limited to a specific sensory circuit. I performed a forward genetic screen to uncover determinants of *ncx-5* transcriptional regulation. The screen yielded a mutant containing very faint expression. We are currently attempting to identify the underlying lesion within this mutant. In order to study cis-regulation of *ncx-5*, I dissected the *ncx-5* promoter sequence into two 700bp portions. I fused each portion to the coding sequence for Green Fluorescent Protein (GFP) and generated transgenic animals expressing these truncated promoter::GFP fusions. One of the constructs yielded a transgenic animal with GFP expression in all six sensory neurons, suggesting that this region of the promoter contains the minimal regulatory motif required to activate the wildtype *ncx-5* expression.

In order to find this motif I further dissected this 700bp region and have now identified a 78bp region of the promoter, which is sufficient to activate *ncx-5* expression only in the six sensory neurons. I conducted bioinformatics analysis using JASPAR and identified five transcription factors that potentially bind to this region. The next step is to obtain mutants for these proteins and cross them into a transgenic strain expressing ^{prom}*ncx-5*::GFP. Phenotype of the second generation progeny will be observed under fluorescence to detect any variation. These animals will also be genotyped to verify inheritance of mutation. In addition, I am currently generating mutants of *ncx-5* utilizing the CRISPR-Cas9 system. The mutation is designed to knock out expression of the gene, allowing us to test any resulting effects on behaviour, such as gas sensation and feeding abilities. A combination of the promoter dissection protocol and the forward genetic screen will allow us to develop a better understanding of how this family of proteins are regulated. Obtaining a null mutant for *ncx-5* via CRISPR will help us understand more about the function of *ncx-5 in* the gas sensing circuit it is expressed in.

P351/B359

NF90 and NF45 Are Chromatin Regulators of Inducible Gene Expression.

T. H. Wu, L. Shi, J. Adrian, M. Shi, R. V. Nair, M. P. Snyder, P. N. Kao; Stanford University School of Medicine, Stanford, CA.

NF90 and its heterodimeric partner protein NF45 are nucleic acid-binding proteins that have been established to regulate RNA splicing, stabilization and export. The roles of NF90 and NF45 in chromatin regulation of gene transcription has not been comprehensively characterized. We used chromatin immunoprecipitation followed by deep sequencing (ChIP-seq) identified 9,081 genomic sites specifically occupied by NF90 in K562 cells. One third of NF90 peaks occurred at promoters of annotated genes. NF90 occupancy colocalized with chromatin marks associated with active promoters (H3K9ac) and strong enhancers (H3K27ac). Comparison with 150 ENCODE ChIP-seq experiments revealed that NF90 clustered with transcription factors exhibiting preference for promoters over enhancers (*POLR2A*, *MYC*, *YY1*). Integrating NF90 ChIP-seq data with differential gene expression analysis following shRNA knockdown of NF90 in K562 cells revealed that NF90 regulated expression of immediate early genes *EGR1*, *FOS*, and *JUN*. In HEK293 cells, serum starvation followed by stimulation with Phorbol 12-myristate 13-acetate (PMA) induces dynamic and reciprocal binding of NF90 and NF45 at promoters of these immediate early transcription factors. In cells stably transfected with doxycycline-inducible shRNA vectors targeting NF90/ILF3 or NF45/ILF2, doxycycline-mediated knockdown of NF90 or NF45 attenuated the inducible expression of *EGR1*, *FOS*, and *JUN* at the levels of transcription, RNA and protein. Taken together, we present evidence that NF90 and NF45 are constitutively expressed transcription factors pre-existing at the promoters of immediate early genes. Dynamic and reciprocal chromatin binding of NF90 and NF45 at immediate early promoters are observed upon stimulation, and NF90 and NF45 contribute to inducible expression of immediate early genes. NF90 and NF45 may thus serve as chromatin regulators of the immediate early response.

New Emergent Properties of Transcription Factor Dynamics and Their Interactions with Chromatin.

D. A. Garcia[1,2,3], D. M. Presman[4,1,5], G. Fettweis[1], V. Paakinaho[6,1], C. Jarzynski[2,3,7], A. Upadhyaya[2,3], G. L. Hager[1]; [1]Laboratory of Gene Expression and Receptor Biology, National Cancer Institute, National Institutes of Health, Bethesda, MD, [2]Department of Physics, University of Maryland, College Park, MD, [3]Institute for Physical Science and Technology, University of Maryland, College Park, MD, [4]Universidad

de Buenos Aires, Buenos Aires, ARGENTINA, [5]IFIBYNE, UBA-CONICET, Universidad de Buenos Aires, Facultad de Ciencias Exactas y Naturales, Buenos Aires, ARGENTINA, [6]Institute of Biomedicine, University of Eastern Finland, Kuopio, FINLAND, [7]Department of Chemistry, University of Maryland, College Park, MD.

Single-molecule tracking allows the study of transcription factor dynamics in the nucleus, giving important information regarding the search and binding behavior of these proteins with chromatin in *vivo*. However, these experiments suffer from limitations due to photobleaching of the traced protein and pre-assumptions on exponential behavior required for data interpretation, potentially leading to serious artifacts. Here, we developed an improved method to account for photobleaching effects, theory-based models to accurately describe transcription factor dynamics, and an unbiased model selection approach to determine the best predicting model. A new biological interpretation of transcriptional regulation emerges from the proposed models wherein transcription factor searching and binding on the DNA and nuclear microenvironment heterogeneity result in a broad distribution of binding affinities and accounts for the power-law behavior of transcription factor residence times. Moreover, two types of confinement are discovered; one related with specific DNA interaction and a second one related to liquid-liquid phase separation. The latter shows the importance of phase separation in transcriptional regulation and gene expression.

P353/B361

The Quaternary Structure of the Mineralocorticoid Receptor Depends on Ligand and Dna Binding.

T. A. Johnson[1], D. Alvarez de la Rosa[2], G. Fettweis[1], G. Hager[1]; [1]National Cancer Institute, NIH, Derwood, MD, [2]Department of Basic Medical Sciences (Physiology), Universidad de La Laguna, La Laguna, SPAIN.

The mineralocorticoid and glucocorticoid receptors (MR and GR) are evolutionarily related nuclear receptors with high sequence conservation and a shared hormone response element (HRE). Both receptors are activated by glucocorticoids, but MR can be selectively activated by aldosterone. It has recently been proposed that liganded GR dimers form tetramers upon DNA binding in live cells. We show that liganded MR also adopts higher quaternary arrangements in live cells, using the imaging technique Number & Brightness (N&B). MR adopts a tetrameric organization in the nucleoplasm and forms complexes with an average of 7 receptor units upon binding an HRE. Interestingly, MR antagonists eplerenone and spironolactone induced intermediate oligomerization arrangements, strongly suggesting that higher order oligomerization is essential for receptor activity. With corticosterone, GR can incorporate into MR complexes partially displacing MR monomers. Genome-wide gene expression and receptor binding studies suggest corticosterone liganded MR and GR in the same cells have potentially complex functional interactions, contributing to receptor-specific signaling. Certain genes respond to only one receptor while others respond to both receptors. The interaction of these two closely-related receptors has important implications for the mechanisms for glucocorticoid signaling and transcription factors in general.

P354/B362

Allelic Exclusion of Telomeric Variant Surface Glycoprotein Genes in Trypanosomes Regulated by Phosphoinositides.

I. Cestari; McGill University, Montreal, QC, CANADA.

The mechanisms by which eukaryotes control allelic exclusion remain poorly understood. The single-celled protozoan pathogen *Trypanosoma brucei* exclusively expresses one variant surface glycoprotein (VSG) gene at a time out of ~ 2,500 VSG genes, and VSG transcription occurs at one of the 20 telomeric expression sites (ESs). *T. brucei* periodically changes VSG expression by transcriptional switch between ESs or VSG gene recombination, and this process is essential for *T. brucei* evasion of the host antibody response by antigenic variation. We identified a telomeric ES multiprotein complex that controls allelic exclusion of VSG genes. Its activity is regulated by a phosphoinositide system which involves a phosphatidylinositol phosphate 5-phosphatase (PIP5Pase) enzyme that binds repressor activator protein 1 (RAP1). Knockdown of PIP5Pase results in simultaneous transcription of all telomeric and subtelomeric VSG genes. PIP5Pase dephosphorylates PI(3,4,5)P3 which prevents this metabolite interaction with RAP1, and thus preserves RAP1 association to ES chromatin and results in transcriptional repression of VSG genes. Catalytic mutations of PIP5Pase that inhibit PI(3,4,5)P3 dephosphorylation affect RAP1 association with ES chromatin and result in VSG transcription, i.e., loss of allelic exclusion. This mechanism, which is also essential for silencing VSG gene transcription during parasite development from mammalian infectious to non-infectious stages, might be conserved in other eukaryotes.

P355/B363

Gamma-tubulin Gene Intron Length Polymorphism of Different *Camelina* Species.

A. I. Yemets[1], R. Y. Blume[1], A. N. Rabokon[1], Y. V. Pirko[1], E. B. Cahoon[2], Y. B. Blume[1]; [1]Institute of Food Biotechnology and Genomics, Kyiv, UKRAINE, [2]University of Nebraska, Lincoln, NE.

Different species from the genus *Camelina* could be considered as promising sources for oil production. One of them, cultivated species of false flax (*C. sativa* L. Crantz.) have been the focus of many investigations to date, but other representatives of this genus are underused despite their potential utility as a germplasm donors for *C. sativa* genetic improvement. In addition, a limitation on broader use of *C. sativa* as a genetic model and for gene editing is its hexaploid nature. In this study, DNA profiling of six *Camelina* species (*C. microcarpa*, *C. rumelica*, *C. hispida* var. *grandiflora*, *C. Alyssum*, *C. laxa and C. sativa*) was conducted basing on assessment of γ-tubulin intron length polymorphism. Because only two copies of γ-tubulin gene are represented in a diploid genome, ploidy can also be evaluated with this method. PCR was performed using degenerate primers, and amplification products were analyzed electrophoretically in a non-denaturing acrylamide gel. Among seven studied *C. microcarpa* accessions obtained from USDA (http://www.ars-grin.gov/), two samples (PI650134, PI650135) possessed atypical γ-tubulin intron patterns. *C. microcarpa* had 4 amplicons of 507 bp, 528 bp, 557 bp, 620 bp. The PI650134 accession contained four amplicons, two being similar to *C. rumelica* - 510 bp and 578 bp, as well as 553 bp and 700 bp fragments. The PI650135 accession had two fragments only - 507 bp and 600 bp, which are unique compared to other studied *Camelina* species. Molecular genetic analysis using SSR markers confirmed differences among the six camelina species. Previously, Galasso et al. (2018) described accessions characterized by atypical genetic profiles based on β-tubulin intron length polymorphism. Brock et al. (2019) described the PI650135 accession as a separate species *C. neglecta*. γ-Tubulin intron profiles of *C. Alyssum and C. sativa* were very similar to *C. microcarpa*, which could be

explained by their common origin. In *C. rumelica,* two fragments of 510 bp and 578 bp were found, while *C. hispida* possessed high number of fragments (about 10) of 498-956 bp length. Together, these results provide evidence of high polymorphism of this species. Based on our findings, we can conclude that *C. neglecta and C. rumelica* are diploid species and, as such, their use could simplify transformation or genome editing of the hexaploid *C. sativa*.

P356/B364

A Functional Intronic Minisatellite VNTR 2-1 in Human Telomerase Gene Regulation.

X. Zhu, T. Xu, C. Dugger, J. Zhu; Washington State University, Spokane, WA.

Abstract Telomerase is critical for telomere maintenance in human stem cells and cancer cells but silenced in most somatic cells. Intronic regions of the human telomerase gene (hTERT), but not those of the mTert gene, play an important role in hTERT expression. Here we demonstrated that, VNTR 2-1, a 42bp/unit minisatellite located in the hTERT intron2 acts as an enhancer element that regulates hTERT promoter activity. Our data showed that 2-32 VNTR 2-1 repeats were able to induce the luciferase activity of pGL3 reporter vectors; and histone mark H3K4me2 was detected on its endogenous locus in K562 cells indicating the potential location of enhancers. By searching from public ChIP-seq database, several bHLH family transcription factors were found bind to the genomic region of hTERT VNTR 2-1 that possibly through interaction with the Ebox motifs. Consequently, we hypothesized that VNTR 2-1 contains functional *cis*-regulatory elements that recruit transcription factors (TFs) to facilitate human-specific regulation of the telomerase gene. To test this hypothesis, we first verified the functional role of Ebox clusters presented in VNTR 2-1 repeats using reporter assay. The Ebox mutation constructs lost over 90% of luciferase activity compare to the WT VNTR 2-1 constructs. Because there were numerous publications verified the interaction of bHLH family proteins with Ebox motifs, two bHLH TFs, USF1 and MNT, were selected for further study. As shown by the qRT-PCR and hTERT BAC reporter, USF1, dimerized with USF2 can upregulate hTERT expression whereas MNT repressed this activity. This is consistent with their general role in gene transcription. Future experiments will focus on identifying new transcription factors and validating their functions toward hTERT expression. This research will gain the understanding of genomic repetitive sequence as well as the molecular mechanisms of telomerase regulation. Key words: VNTR, hTERT regulation, intronic enhancer, transcription factors

P357/B365

Deletion of the CDK Mediator Subunit Cdk8 Exhibits a Memory Effect on *HAP4* Expression.

P. Peterson, Z. Liu; University of New Orleans, New Orleans, LA.

The transcription factor Hap2/3/4/5 is a master regulator of respiratory gene expression and mitochondrial biogenesis in *Saccharomyces cerevisiae*. The activity of this complex is largely dependent on the protein level of Hap4, which is regulated in part by the Mediator complex, a highly conserved transcriptional coactivator that interacts with RNA polymerase II. In yeast, the 25 subunits of Mediator are divided into four modules that play differential roles on gene expression. While the Head, Middle, and Tail modules have been shown to positively regulate transcription, evidence suggests that the CDK module is a negative regulator of gene expression. Mutants of the CDK module subunits Med12, Med13, Cdk8, and CycC have induced expression of *HAP4*. Deletion of Cdk8 exhibits a "memory" effect on *HAP4* expression. When a *HAP4-lacZ* reporter gene is introduced to *cdk8Δ* mutants, there is a low induction (LI) of *HAP4* expression compared to wild type. However, when the *cdk8Δ* gene deletion is introduced

into wild-type cells already carrying the *HAP4-lacZ* reporter gene, there is a high induction (HI) of *HAP4* expression. The "memory" effect of *HAP4* expression in *cdk8Δ* is also found in *med12Δ and med13Δ,* but not in CycC mutant cells. *HAP4* expression in the *cdk8Δ* LI and HI strains remains stable after many generations, with a very low frequency of conversion from the high to low induction phenotype, but not the reverse. The "memory" effect is also maintained in the diploid strains when crossed with either wild-type or *cdk8Δ* deletion strain. Similar results were found for *med12Δ and med13Δ* mutants after crossings*. To* address the mechanism responsible for maintaining "memory", we introduced gene mutations involved in histone modification and chromatin remodeling, namely, *htz1Δ, gcn5Δ, and ldb7Δ*, *in to cdk8Δ* LI and HI strains. *gcn5Δ and ldb7Δ* lead to reduced *HAP4-lacZ* expression in HI and LI *cdk8Δ* mutants to a similar extent. Deletion of the histone H2A variant *HTZ1 in* HI *cdk8Δ* strain led to the low induction phenotype. In LI *cdk8Δ* strain, *htz1Δ* did not change the low induction phenotype of *HAP4* expression. Interestingly, *htz1Δ in* wild-type strain resulted in a low induction of *HAP4-lacZ* expression. Our results suggest that this novel "memory" phenotype of altered *HAP4* expression due to *cdk8Δ* is epigenetic and the result of changes in chromatin structure.

P358/B366

Nuclear Actin in Transcription by RNA Polymerase II.

S. Kyheröinen, T. Viita, M. Sokolova, M. Vartiainen; University of Helsinki, Helsinki, FINLAND.

Actin is a protein that exists in cells both as monomers and as filaments. Although widely known as a major component of the cytoskeleton, actin also localizes to the nucleus, where it has important roles especially related to gene expression. Actin is a part of several chromatin remodeling complexes and takes part in pre-mRNA processing. Intriguingly, actin has also been linked to transcription in various ways and nuclear actin levels appear to be actively regulated to sustain maximal transcription. Actin co-purifies with all three RNA polymerases and has been suggested to interact with positive transcription elongation factor b (P-TEFb) essential in pause-release of Pol II. However, the biochemical details of these interactions are not known and this work focuses on characterizing them using a variety of tools. Our ChIP-seq results show a co-occupancy of actin and Pol II on transcription start sites of most transcribed genes as well as on the gene bodies of highly expressed genes and current experiments are focusing on the biochemical details of the possible interaction between actin and whole Pol II. Interestingly, our mass spectrometry screen for nuclear actin binding partners contained P-TEFb and a set of general transcription factors. Further characterization of mass spec hits showed that Cdk9, the kinase subunit of P-TEFb, binds actin monomers directly in biochemical experiments and inhibits actin polymerization and this applies to the whole P-TEFb complex as well. Actin and Cdk9 also interact in co-immunoprecipitation experiments. As most of P-TEFb is in cells bound to an inhibitory complex 7SK snRNP, ongoing experiments are now assessing the possibility that actin could help releasing P-TEFb from the inhibition, thus allowing it to act in the pause-release. In conclusion, these results support the positive role of nuclear actin in transcription.

P359/B367

Investigating the Coordination of Global Transcriptional Scaling with Cell Size and Growth.

M. P. Swaffer[1], G. Marinov[1], H. Zheng[2], W. Greenleaf[1], R. Reyes[2], J. Skotheim[1]; [1]Stanford University, Stanford, CA, [2]McGill University, Montreal, QC, CANADA.

Cell size varies widely amongst cell types or environmental conditions, and during the life cycle of a proliferating cell its size will increase, on average, twofold. However, how the basic biosynthetic process of the cell, such as transcription, adapt to account for changes in volume has remained poorly understood. More specifically, it was first described in the 1970s that as cell increase in size the rate of RNA-synthesis per gene increases in proportion to cell size - this size-scaling of RNA-synthesis ensures RNA and protein concentrations are kept constant and is likely critical for maintaining biochemical reaction rates and setting the cellular growth rate. Despite the apparent importance of this phenomenon, the molecular basis of this size-scaling control has remained unexamined. Using a combination of ChIP-seq, chromatin-proteomics, and super-resolution (PALM) single-molecule imaging, we have determined that the RNA polymerases occupancy per gene increases across the genome as cell size increases. Furthermore, this increase is not correlated with any major change in histone occupancy or chromatin accessibility. Consistent with this, most histone modifications measured are unchanged with the exception of those downstream of the elongating polymerase. Nearly all transcription factors examined, including the major subunits of the RNAPII Pre-Initiation complex (PIC), increase their fractional occupancy on the genome in proportion to size, concomitant with the increased polymerase occupancy. Given that we have also observed that the amount of polymerase and transcription-factor molecules per cell is strongly correlated with cell size, we considered whether a critical subunit of PIC was limiting for transcription such that as the amount of this factor increases so would global transcription rates. To test this idea, we have measured polymerase occupancy after local perturbation of the nuclear concentrations to PIC components. Based on these data we propose a working model where global transcription rates are set via the combinatorial amount of multiple different PIC subunits - each of which is partially limiting.

P360/B368

Coordination of Protein Homeostasis with Cell-volume in Budding Yeast.

K. Claude, D. Bureik, K. M. Schmoller; Helmholtz Zentrum München, München, GERMANY.

In proliferating cells, protein homeostasis is tightly coordinated with cell-volume and most proteins are kept at a constant, cell-volume independent concentration. While well suited for most proteins, a constant concentration imposes a problem for DNA-binding proteins such as histones, which on the contrary are required at a constant amount. Indeed, using live-cell fluorescence microscopy, we find that in budding yeast the histone concentration decreases with increasing cell-volume. This raises the question of how cells achieve to produce histones in proportion to DNA content even though total protein production increases with cell-volume. To identify the cell-volume dependence of histone transcript concentrations, we controlled cell-volume through inducible expression of the G1/S inhibitor Whi5. Using RT-qPCR, we find that for control genes the mRNA concentration relative to total RNA stays constant with increasing cell-volume. In contrast, the relative concentration of histone mRNA decreases in inverse proportion to cell volume. Next, we asked whether histone promoters are sufficient to establish the cell-volume-dependence of histone homeostasis. Using RT-qPCR and flow cytometry, we find that histone promoters driving expression of a fluorescent reporter result in a decrease of reporter

mRNA concentration with increasing cell-volume, as opposed to the *ACT1* promoter, which leads to a constant, cell-volume independent, mRNA concentration. In conclusion, we find that histone transcription is limited by the DNA template, which is in contrast to the production of other proteins such as Act1, where transcription is limited by the transcriptional machinery. In addition, such a mechanism also explains the differential ploidy dependence of transcription driven by histone and control promoters. Thus, our work identifies a novel regulatory mechanism that enables cells to couple histone production to ploidy rather than cell size.

P361/B369

Function of the IR Cluster Located in the Upstream of the *Oct3/4 Ge*ne.

Y. Yamamoto[1], O. Miura[2], T. Ohyama[1]; [1]Dept. Biol., Waseda University, Tokyo, JAPAN, [2]Res. Inst. For Sci. An d Eng., Waseda University, Tokyo, JAPAN.

Many studies have been carried out to understand the function of inverted repeat (IR) sequences that read the same from 5' to 3' in either strand. IRs are also referred to as palindromes. The function of IRs, however, is still elusive. The mouse *Oct3/4* gene, which is known as a key gene for pluripotency, has a cluster of six IRs in ~1.5 - ~2 kb the upstream. Each of them has a potential to transform into a cruciform. It is known that expression of the *Oct3/4* gene is regulated by its proximal promoter (PP), proximal enhancer (PE), and distal enhancer (DE). Considering that the DE harbors the IR cluster, this cluster may play some important role in the *Oct3/4* expression. In order to substantiate this hypothesis, applying the CRISPR/Cas9-based genome editing to the mouse genome in the ES cells, the IRs in the cluster were replaced with mirror repeat sequences that retain the sequences of the repeat unit in the respective IRs. In the resulting cells, these mutations slightly decreased the *Oct3/4* expression, while the transcription levels of the noncoding RNAs originated from the DE (i.e., DE-ncRNAs) were increased. In addition to this, expression of the *Sox2*, *Klf4*, *Nanog*, and *Esrrb* genes showed a similar change to that of the DE-ncRNAs expression. These results suggest that the IR cluster has a positive effect on the *Oct3/4* expression and a negative effect on the expression of the *Sox2*, *Klf4*, *Nanog*, and *Esrrb* genes through the expression of the DE-ncRNAs. In this meeting, we will discuss the putative function of the IR cluster.

P362/B370

Development of CRISPR Tool Cell Lines for Targeted Gene Expression Study.

S. Kumari, S. Philip, D. Douglas, W. Shu, J. Huuskonen; ATCC Cell Systems, Gaithersburg, MD.

Developing technologies for targeted disruption of gene expression will provide powerful tools for studying gene function. To date, various methods for achieving loss-of-function (LOF) outcomes have been developed, including approaches employing RNA interference (RNAi) and CRISPR (clustered regularly interspaced short palindrome repeats)/Cas9 mediated gene perturbation (Nature Biotech (2016) 34(6): 631-634). In mammalian cells, RNAi is the predominant method for programmed knockdown of mRNAs, but its utility is limited by confounding off-target effects (Nat. Methods (2006) 3:777-779). The RNA-guided CRISPR-associated nuclease Cas9 provides an effective means of introducing targeted LOF mutations in the genome. Cas9 can be programmed to induce DNA double strand breaks (DSBs) at specific genomic loci through guide RNAs (gRNA), which when targeted to coding regions of genes, can create frame shift indel mutations resulting in a LOF allele (N Engl J Med (2019) 380(25): 2475-2477). In addition to the use of the nuclease activity of Cas9, the CRISPR-Cas9 technology can also be repurposed as a sequence-specific, non-mutagenic gene regulation tool. Coupling of the

engineered nuclease-deficient Cas9 (dCas9) to a transcriptional repressor domain can robustly silence expression of endogenous genes with high specificity, resulting in 'CRISPR interference' (CRISPRi) (Cell (2013) 152(5): 1173-1183). Here we report the creation of Cas9 expressing HEK293 and CRISPRi A549 cell lines, in which the Cas9 or KRAB-dCas9 expression cassette was integrated into AAVS1 safe harbor locus. The integration of knock-in allele was confirmed at genomic and translational levels in both cell lines. When gRNAs targeting p53 and RFP genes were delivered into HEK-293 Cas9 cells, DNA DSBs at intended sites were detected using T7E1 assay and Sanger sequencing, and the expression of p53 and RFP proteins was significantly disrupted. In A549 CRISPRi cells, gRNAs targeting p53 and SETD9 promoter regions repressed p53 and SETD9 gene transcription approximately 75% and 65%, respectively. In p53 gRNA expressing virus infected A549 CRISPRi single cell clones, approximately 95% p53 transcription repression was detected. Taken together, our data suggest that these CRISPR Tool cell lines are valuable tools that greatly simplify the study of human gene function and provide potential applications for precise gene knockout and knockdown in human cells.

P363/B371

Digestive Enzyme Genes of a Sundew, *Drosera Adelae*: Mechanisms Underlying the Adhesive Trap-specific Gene Expression.

N. Arai, Y. Ohno, T. Ohyama; Dept. Biol., Waseda University, Tokyo, JAPAN.

Carnivorous plants have adapted themselves to the nutrient-deficient habitats. They can obtain nitrogen and phosphate, which are necessary for amino acid and nucleotide syntheses, from insects. *D. Adelae* is a carnivorous plant with an adhesive trap, which secretes viscous digestive fluid from the glandular tentacles on the surface of the leaves. In the digestive fluid, there are many proteins that are induced by wounding and pathogen attack in ordinary plants. Therefore, *D. Adelae* is thought to make use of the defense-related proteins for self-defense and carnivory (Okabe *et al.*, 2005). Recently, we explored expression mechanisms of digestive enzymes in the fluid and suggested that the S-like RNase gene *da-I* is regulated by glandular cell-specific demethylation of its promoter (Nishimura *et al.*, 2013, 2014).In the current study, focusing on five digestive enzyme genes, *Cysp1*, *Glu1*, *Hel1*, *Chi1* and *Tlp1*, we examined the relationship between their expression and promoter methylation. The result showed that most of these genes are exclusively expressed in a glandular cell-specific manner, but methylation profiles differ among these genes. For *Cysp1* and *Glu1*, the promoters were unmethylated only in glandular cells like *da-I*. However, for *Chi1* and *Tlp1*, the promoters were unmethylated in all organs. Interestingly, the gene encoding the DNA demethylase DEMETER, which induces genome-wide demethylation in endosperm in Arabidopsis and rice (Kawashima and Berger, 2014), was also highly expressed in the glandular cells of *D. Adelae*. Accordingly, it seems that *D. Adelae* makes some of the defense-related genes be constitutively expressed via unmethylation in a glandular cells-specific manner for carnivory.

Genomic an notation of 45,600 Bp Region of 3l Chromosome in D. *Takahashii*.

E. N. White, 66621, T. Sadikot; Washburn University, Topeka, KS.

Drosophila melanogaster, the common fruit fly, is one of the most versatile model organisms in biology, used for a wide range of research centered around cellular mechanisms of complex eukaryotes. In this project we use the D. *melanogaster* genome as a reference to identify and annotate coding regions in Drosophila *takahashii*. This project is part of a collaborative effort of the Genomics Education

Partnership (GEP). Here we use conservation-based analysis and various online tools such as the Drosophila melanogaster genome browser, Flybase, Gene Model Checker and Gene Record Finder to analyze a 45,600 base pair segment of chromosome 3L in *D. takahashii* labeled contig 42. The BLAST of D. *melanogaster* indicates the presence of genes ADP-ribosylation factor GTPase activating protein 3 (ArfGAP3), Maelstrom (mael), lethal(3)04053 (l(3)04053), CG32454, CG14451, CG11367, CG32452, CG14450, CG8745, Aminotransferase class-III (Oat) and CG11241 genes in the contig. The analysis of the *D. takahashii* sequence supports the BLAST results for the aforementioned genes except for CG8745 and Oat which are found in a different region in D. *melonogaste*r. Discrepancy in exon number and placement was resolved using the small exon finder and protein BLAST analysis to select the most conserved model. The results and the data collected from this research will be submitted for review and inclusion to the GEP data repository.

P365/B373

Transcriptomic an alysis of Novel Mycobaacteriophage Herbertwm.

T. James, G. Solini, S. Paudel, M. Saha, M. Forsyth; College William & Mary, Williamsburg, VA.

The genus *Mycobacterium* contains over 190 species and is responsible for significant morbidity and mortality in humans and other animals. In addition to well-studied human pathogens such as *Mycobacterium tuberculosis, leprae,* and*abscessus*, the genus includes many non-tuberculosis environmental species that dwell in the soil and water supply, species that may serve as useful models for the pathogenic species. With the recently reported successes in phage therapy, there has been an increased interest in expanding the diversity of phages that infect hosts within the *Mycobacterium* genus. The goal of this project was to identify phages that infected *Mycobacterium aichiense,* a host for which there are currently no reported bacteriophages. Using standard methods to isolate phages from soil samples, we isolated approximately 50 phages infecting this host from local soil samples. All of the phages had consistently low titers and required optimization of DNA isolation techniques. Ten isolates were sequenced. In each case, sequencing resulted in a ~50 kb phage that may represent a new subcluster within the a cluster of mycobacterial phages; this sequence corresponds to a prophage in the *M. Achiense* genome that we called Herbert WM. Surprisingly, in each sample, there was also a 11 kb "phagelet" that shared little identity with the 50 kb HerbertWM prophage. The phagelet encodes 20 genes including a terminase, a serine-threonine kinase, a head-to-tail adaptor, a head-to-tail stopper and 16 hypothetical proteins of unknown function. While all the isolates contained both the prophage and the phagelet, the stoichiometry of the two phages differed among the various samples. In order to investigate this novel "phagelet" further, we performed RNA-Seq analysis at different time points following infection of the host, including: a time point before phage was added to the sample; and then at 0, 5, 15, 30, 60, and 120 minutes following infection. This analysis revealed, somewhat surprisingly, that in addition to expression of the repressor, many prophage genes were expressed at low levels even in the absence of infection with the phagelet. Phagelet genes were expressed as early as t=5 minutes post infection and continued to increase throughout the time periods analyzed with the few structural genes being expressed late in infection. Prophage (Herbert WM) genes did not significantly upregulate until t=60 min. This represents the first instance of satellite-like phage in the mycobacterial genus, one that may provide valuable tools for manipulating and understanding mycobacterial genomes.

P366/B374

Developing Tools to Detect Translation of the 3' Untranslated Regions of Messenger RNAs.

A. V. DePass[1], A. Karasik[2], N. R. Guydosh[2]; [1]Quinnipiac University, Hamden, CT, [2]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.

Upon viral infection multiple host response mechanisms are initiated, such as the activation of Ribonuclease L (RNase L). The canonical role of RNase L is to cleave host and viral mRNAs. However, activated RNase L is also known to bind to ribosome termination/recycling factors ATP Binding Cassette subfamily E member 1 (ABCE1) and Eukaryotic Release Factor 3 (eRF3) indicating its potential role in ribosome recycling and termination. When ribosome recycling is impaired, ribosomes can bypass the canonical stop codon and translate the 3' Untranslated Region (3'UTR) of mRNAs. Prior ribosome profiling data from our lab suggests that RNase L interferes with ribosome recycling, and potentially triggers 3'UTR translation. Here we have developed 3'UTR reporters to investigate 3'UTR translation in RNase-L activated cells and detect myc-tagged 3'UTR peptides by Western Blot. We observe translation events within the 3'UTRs of non-activated cells, establishing the utility of these reporters. Future studies may investigate changes in 3'UTR translation within RNase-L activated cells.

The Complete Chloroplast Genome of *Lagenaria Siceraria* (mol.) Standl.

F. O. AWALA, B. A. Odogwu, I. O. AGBAGWA, B. C. Ndukwu; University of PORT HARCOURT, PORT HARCOURT, NIGERIA.

Lagenaria siceraria (Mol.) Standl. commonly known as calabash plant in West Africa, is a highly utilized aesthetic crop because it exhibits the widest variations in fruit shape. However, the phenotypic variation of the plant's fruit shape is continuous and difficult to quantify, with polymorphic and numerous landraces exhibiting diversity in fruit shapes. To decipher these variation, a study on the complete chloroplast genome of the species was carried out. A total of 44 sequences of *L. siceraria* stored in the National Center for Biotechnology Information (NCBI) genebank was extracted and annotated using GeSeq program in CHLOROBOX. The organellar genome map of the species is a circular molecule of about 157,145 base pairs. The chloroplast genome has two inverted repeats regions a and B (IR_A and IR_B) of 25,910bp that contain the rRNA genes and a few other duplicated genes. These repeats are seperated by two single-copy sequences, one small and one large (of 8,735bp and 17,974bp respectively) that contain the bulk of the tRNA and protein-coding genes, with an overall Guanine-Cytosine content of 37.7%. There are a total of 131 genes in the genome, including 86 protein-coding genes, 37 tRNAs genes and 8 rRNAs genes. Also, the intergenic and untranscribed region such as photosystem II and tRNA genes were highly variable in the chloroplast genome of *Lagenaria siceraria*., All aligned sequences showed that *L. siceraria* chloroplast genome possesses high sequence similarity, which is an indication that it is conservative, although it possess some region of divergence. Coding regions has been recorded to be more conserved than the non-coding regions; hence the ribulose bisphosphate carboxylase gene (rbcL) and Acetyl-coenzymeA carboxylase gene (accD) found in the species are coding regions which has been reported to be divergent in plastome which may be linked to the variations in the fruit shape of the crop. This study therefore holds potential in the improvement of L*. siceraria*, which will enhance the utilization and demand of the crop in sub-Sahara region. Keywords: Chloroplast, Genome, Gene expression, *Lagenaria siceraria* (Mol.) Standl.

Transcription Factor Foxa1 Clusters Dna through Wetting-mediated Capillary Forces.

T. Quail, S. Golfier, D. Oriola, J. Brugues; Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, GERMANY.

Direct interactions between enhancers and promoters are necessary for the activation of gene regulatory programs in vivo. However, how transcription factors, co-factors, and general transcriptional machinery work in concert to physically bring DNA together in space and time remains unclear. Here, we used super-resolution TIRF to image the interactions of single-molecules of linearized lambda-phage DNA and Forkhead Box Protein A1 (FoxA1). We discovered that FoxA1 wets DNA, generating capillary forces that reel-in DNA into clusters on the order of 20 KB in a DNA tension-dependent manner. To understand the source of this reeling-in force, we imaged pairs of DNA molecules that were bound spatially proximal to each other, and we found that these DNA molecules exhibited “zipping”, consistent with a mechanism where FoxA1 minimises its surface area due to surface tension effects, and, consequently, generates capillary forces. We proposed that the origin of these capillary forces is a combination of FoxA1 self-interactions and FoxA1-DNA adhesion. To test this theory, we generated a C-terminal truncation of FoxA1, a disordered region that we thought may play a role in FoxA1 self-interaction. FoxA1ΔCTD did not cluster DNA, suggesting that FoxA1-FoxA1 interactions are relevant for capillary force generation. This reveals that transcription factors could display a range of behaviors depending on their structure. To investigate this, we used Tata-Box Binding protein (TBP), a general transcription factor, and linker histone H1, a chromosomal architecture protein structurally similar to FoxA1. We found that TBP wets DNA, forming droplets that translocate along the strand, though was unable to reel-in DNA. However, H1 reeled-in DNA with stronger capillary forces, consistent with its known compacting activity. We propose that capillary-force-induced DNA clustering is a novel mechanism that may play a fundamental role in DNA organization in the cell nucleus.

RNA Localization and Transport

P369/B377

Localized RNA Translation as a Modifier of Protein Properties and Function.

A. N. Gasparski, K. Moissoglu, S. Mili; National Cancer Institute, NIH, Bethesda, MD.

The localization of RNA transcripts to particular subcellular compartments is a mechanism used to localize numerous transcripts in polarized cells. RNA localization plays a critical role in several processes, including cell migration, synaptic plasticity and embryonic axis specification, and is deregulated in cancer metastasis and many neurological diseases. In most cases, localized RNAs are believed to be locally translated, which can lead to an increase in protein concentration at these locations. However, recent evidence has indicated that translation can have additional consequences on the function of the encoded proteins. Some potential mechanisms include interactions between nascent proteins and RNA-bound factors, which can direct the released protein to distinct fates, or the co-translational assembly of proteins into complexes. This study investigates the hypothesis that RNA localization affects the encoded protein’s function by restricting translation to specific subcellular regions. To test this hypothesis, we use as a model the localized Net1 RNA, which is concentrated at peripheral protrusions and encodes a Rho family GTPase activator. We have developed a method that allows us to specifically mislocalize the Net1 RNA from protrusions and force it to adopt a perinuclear distribution. Interestingly,

when the Net1 transcript is mislocalized in MDA-MB-231 cells, RhoA signaling is decreased concomitant with a reduction in cell migration speed and invasion. These results are consistent with the model that local production of Net1 affects the function of the encoded protein, and thus alters the regulation of downstream cellular physiological processes.

P370/B378

Mitochondrial Volume Fraction Controls Translation of Nuclear-encoded Mitochondrial Proteins.

T. Tsuboi[1], M. Viana[2], F. Xu[1], S. Rafelski[2], B. Zid[1]; [1]University of California, San Diego, La Jolla, CA, [2]University of California, Irvine, Irvine, CA.

Mitochondria are dynamic in their size and morphology, yet must also precisely control their protein composition according to cellular energy demand. We have found that cells are able to use mitochondrial morphology to post-transcriptionally coordinate protein expression with metabolic demands through enhanced mRNA localization to the mitochondria. As yeast switch to respiratory metabolism they increase their mitochondrial volume fraction, this drives the localization of nuclear-encoded mitochondrial mRNAs to the surface of the mitochondria. Through artificial tethering experiments, we show that this mitochondrial localization is necessary and sufficient to increase protein production to levels required during respiratory growth. Furthermore, we find that this mRNA sensitivity to mitochondrial volume fraction is driven by the speed of translation of the ORF. This points to a mechanism by which organelle volume fraction provides feedback to regulate organelle-specific gene expression through mRNA localization while potentially circumventing the need to directly coordinate with the nuclear genome.

RNAs Are Transported on Microtubules and Localized to the Sarcomere in Skeletal Muscle.

L. T. Denes, E. T. Wang; University of Florida, Gainesville, FL.

RNA localization and local translation of proteins is a critical mechanism by which cells specialize subcellular compartments. Specialized cells with complex cyto-architecture, such as neurons and muscle, have evolved complex mechanisms to ensure proper localization of RNA and local translation of encoded proteins in diverse regions of the cytoplasm. Muscle cells face unique challenges to appropriately distribute RNA. They are large syncytia of thousands of nuclei containing in their common cytoplasm an intricate, force-generating cytoskeletal apparatus that restricts diffusion of gene products. Despite literature describing localized RNAs in muscle, the majority of work in the RNA localization field has focused on neurons. As such, the mechanisms, trans factors, and cis elements involved in localizing RNAs and translational activity in skeletal muscle are poorly understood. In this study, we characterize the localization of known and novel localized RNAs in mouse muscle and assess RNA transport and translation regulation in live muscle cells. We imaged single molecules of RNA in *in vivo* skeletal muscle, finding that many are associated with components of the muscle sarcomere and that the microtubule cytoskeleton is required for efficient RNA distribution from the myo-nuclei. We then used live-cell RNA and nascent peptide tracking in cultured myotubes to interrogate the mechanistic underpinnings of observed in *vivo* localization patterns for target RNAs. We find that translating and non-translating mRNAs are actively transported and associate with the sarcomere in an in *vitro* muscle development paradigm. We additionally sought to characterize the full sarcomere-localized transcriptome. To this end, we utilized a proximity biotinylation approach to label sarcomere Z-lines in myotubes in *vitro*. We

are adapting this method to isolate sarcomere RNAs from in *vivo* muscle and will use RNAseq to identify the full repertoire of sarcomere localized transcripts. This dataset will power bioinformatics analyses that will identify candidate localization-directing cis elements for further evaluation. The results of these efforts will increase our understanding of post-transcriptional gene regulation in basic biology, as well as clarifying the role of RNA localization and local translation in the assembly and maintenance of the muscle sarcomere.

The Polo-like Kinase (PLK-1) Merges the Parental Genome Into A Single Nucleus by Promoting Lamina Disassembly during Mitosis In *C. Elegans* Embryos. G. Velez Aguilera[1], S. Nkombo Nkoula[1], L. Van Hove[1], D. Paouneskou[2], J. Link[2], B. Ossareh-Nazari[1], N. Joly[1], V. Jantsch[2], L. Pintard[1];
[1]Institut Jacques Monod – CNRS – University of Paris, Paris, FRANCE, [2]Department of Chromosome Biology, Max F. Perutz Laboratories , University of Vienna, Vienna, AUSTRIA.

After fertilization, the haploid gametes of egg and sperm are replicated into separate pronuclei surrounded by a nuclear envelope but before the first zygotic division, the nuclear envelopes disassemble, allowing both sets of chromosomes to be incorporated into a single nucleus in daughter cells after mitosis. Here we show that the polo-like PLK-1 phosphorylates the single C. elegans lamin LMN-1 to promote lamina disassembly during mitosis and to merge the parental chromosomes into a single nucleus. We demonstrate that expression of non-phosphorylatable versions of LMN-1 prevents Lamina depolymerization during mitosis, which is sufficient to induce the formation of embryos with a paired nuclei phenotype, containing either the maternal or paternal chromosomes, in each daughter cell at the two-cell stage. Finally, we reconstitute in vitro the assembly of lamin filaments and their depolymerization by PLK-1 and demonstrate the importance of LMN-1 phosphorylation sites in this process. Our findings indicate that PLK-1 is a key regulator of the lamin dynamics in C. elegans and possibly also in other organisms.

P372/B381

Effect of Hiv-1 Infection on the Distribution of the Transmembrane Nucleoporin Pom121.
F. Farzam[1], M. El-Mousawi[1], A. Joseph[2], S. Flemming[1], D. Grunwald[1]; [1]University Massachusetts Med School, Worcester, MA, [2]MustangBio, Worcester, MA.

Over the last decade it became evident that nucleoporins are integrally linked to the life cycle of the HIV-1 genome. Recently an N-terminal truncated form of the nucleoporin POM121C was reported to inhibit HIV-1 replication[1] and earlier it was shown that the knockdown of POM121 inhibited HIV-1 replication at the nuclear import step[2]. Our group had data from a HeLa cell line with an integrated HIV-1 test genome, which carried the BGlg RNA aptamer binding site[3], that showed how POM121 (labeled with tdTomato) relocates within the nuclear envelope and that a sub-fraction of POM121 colocalizes with the viral full-length RNA. Conducting multi-channel imaging experiments with our home-built state of the art microscope, this time using Jurkat, and primary human T-cells infected with pNL4-3-GFP HIV-1 virus (NIH AIDS reagent 11100), we observed progressive changes in the distribution of POM121. Starting from its normal abundance within well-spaced nuclear pores at time zero, POM121 separated into aggregates later in the infection cycle. We show that cells showing this phenotype are

not apoptotic using an an nexin V-Alexa647 co-stain[4] (Biolegend 640912). Our data point towards a new mechanism for at least a sub-class of HIV-1 full length genomes during cell nuclear export that provide further insight into how the HIV virus manipulates the host cells transport machinery, possibly to arm itself for the next round of infection. [1] Saito, H., Takeuchi, H., Masuda, T., Noda, T., Yamaoka, S., 2017. N-terminally truncated POM121C inhibits HIV-1 replication. Torsin Regulation of Lipid Metabolism in Nuclear Membrane Remodeling and Disease.

J. Jacquemyn, A. Carapinha Cascalho, J. Swerts, S. Fernàndez Gallego, J. Foroozandeh, P. Verstreken, **R. E. Goodchild**; VIB/KU Leuven, Leuven, BELGIUM.

Torsins are atypical AAA+ proteins of the endoplasmic reticulum (ER) and nuclear envelope (NE). Their loss causes vesicle-like structures to accumulate in the NE which label for some nucleoporins. The human torsinA gene is also responsible for at least two different neurological diseases: 1) a recessive congenital syndrome and 2) a dominantly-inherited dystonia. We previously showed that fly *dTorsin* regulates the lipid metabolic enzyme, LIPIN, that converts phosphatidic acid (PtdA) into diacylglycerol (DAG) (Grillet, *et al*, Dev Cell (2016). Now, via a mini screen, we genetically define a pathway that functionally links torsin to LIPIN. This includes that the nuclear membrane defects of torsin loss are rescued by RNAi against these genes, while gene overexpression induces their appearance. We also examined the disease relevance of LIPIN dysregulation. This identified excess LIPIN-mediated PtdA conversion to DAG in 1) dystonia patient iPSC-derived neurons, 2) the brains of dominant TorsinA-dystonia mice and 3) three mouse models of recessive TorsinA disease. Further, using *Lipin1* gene knock-out mice, we demonstrated that LIPIN dysregulation contributes to neurodegeneration, abnormal motor behaviors, and poor survival of torsinA disease mice. In conclusion, these data show that torsin loss affects the cell via a pathway that controls PtdA to DAG metabolism. This includes the classic nuclear membrane defects of torsin loss, as well as disease-like pathology and symptoms in torsinA disease model mice.

P376/B385

TorsinA Is a Multi-tool AAA+ ATPase within the Nuclear Envelope That Acts through Distinct Functional Assembly States.

K. Hur, J. Hennen, C. A. Saunders, A. Schoenhofen, J. D. Mueller, **G. Luxton**; University of Minnesota, Minneapolis, MN.

Mutations in the *TOR1A*gene, which encodes the nuclear envelope-localized AAA+ ATPase torsinA, cause a spectrum of poorly understood neurological diseases including DYT1 dystonia and severe arthrogryposis. While torsinA function is required for nuclear-cytoskeletal coupling and nuclear pore complex (NPC) biogenesis, the molecular mechanism(s) underlying how torsinA mediates these functions and their relationship to human*TOR1A*disease pathogenesis remain unclear. Here, we determined the functional assembly state of torsinA in the nuclear envelope of living cells using fluorescence fluctuation spectroscopy. Because AAA+ proteins generally function as homo-hexameric molecular chaperones that structurally remodel their substrates, we expected to observe homo-hexamers of torsinA in the nuclear envelope. In contrast, the in *vivo*homo-oligomerization of torsinA was limited to a homo-trimer. Unexpectedly, the deletion of its membrane-associating N-terminal domain (NTD) resulted in the assembly of torsinA homo-oligomers larger than expected for a homo-hexamer. By measuring the assembly states of constructs containing torsinA monomers that were covalently linked into artificial dimers, trimers, tetramers, pentamers, and hexamers, we revealed that torsinA polymerizes following the rate limiting step of dimerization at discreet sites within the nuclear envelope. Next, we investigated the physiological relevance of torsinA polymerization by testing its role during nuclear-cytoskeletal coupling and NPC biogenesis. Interestingly, we found that torsinA polymerization was required for nuclear-cytoskeletal coupling but dispensable for NPC biogenesis. Moreover, we determined that membrane-association was critical for NPC biogenesis but detrimental to nuclear-cytoskeletal coupling. In fact, nuclear-cytoskeletal coupling was prevented when the NTD was converted into a transmembrane domain or when a previously described proteolytic cleavage event that selectively removes the NTD was inhibited. Finally, we showed that the ability of torsinA to hydrolyze ATP was not important for NPC biogenesis, whereas it was essential for nuclear-cytoskeletal coupling. Taken together, our results suggest that torsinA is a multi-tool AAA+ protein that acts via different functional assembly states to execute distinct functions within the nuclear envelope. We propose that torsinA functions as a soluble polymeric chaperone to promote proper nuclear-cytoskeletal coupling, whereas it mediates NPC biogenesis as a lower-order homo-oligomer by potentially remodeling the inner nuclear membrane.

Cytoplasmic Capes in the Nuclear Envelope Are Closely Associated with Non-Canonical RNA Export and Receive Proteins from the Endosome System.

F. Mattie[1], P. Kumar[2], K. Browder[3], **C. Thomas**[1]; [1]Pennsylvania State University, Univesity Park, PA, [2]Government College for Women Trivandrum, Kerala, INDIA, [3]Genentech, South San Francisco, CA.

It is increasingly clear that nuclear-cytoplasmic communication is not limited to nuclear pores, with both proteins and RNA having alternative routes between the cytoplasm and nucleoplasm. We have previously characterized large invaginations of the nuclear envelope in the *Drosophila* larval salivary gland, known as ‘cytoplasmic capes’, which are enriched for the immature, membrane-bound EGF receptor ligand mSpitz and encapsulate endosome-related organelles containing ubiquitylated proteins.

Closely associated with these structures are groups of perinuclear vesicles strongly resembling those seen at sites of mega-RNP export *via* a budding mechanism. Here, through knockdown of key endosomal regulators, we demonstrate that mSpitz delivery to capes requires passage through the endosomal system despite the immediate connection between the nuclear envelope and the ER. Using an improved in *situ* hybridization technique, we also show that capes are closely associated with sites of RNP export as well as the dFrizzled2 receptor C terminal fragment, a core component of this export pathway. Video microscopy of glands in intact larvae indicates that cytoplasmic capes are stable structures that persist for at least 90 minutes without conspicuous growth. We further show that cytoplasmic capes appear with the growth of the salivary gland rather than its developmental stage. Finally, we show that the large F-actin binding protein βH-spectrin, which modulates endosomal trafficking, as well as its partner α-spectrin are required for cape formation. Cytoplasmic capes therefore represent an interesting subspecialization of the nuclear envelope where endosomal trafficking and RNP export are closely associated.

Mechanism of Nucleotide Binding to TorsinA.

N. Kendrick, A. O. Olivares; Vanderbilt University, Nashville, TN.

The loss of nuclear envelope (NE) integrity leads to several diseases including muscular dystrophy, cardiomyopathy, dystonia, and cancer. Dysfunction in NE protein homeostasis results in changes to NE structure and may drive this loss, though the mechanistic basis for maintaining NE protein folding and assembly remains unclear. TorsinA (TorA) belongs to the AAA+ (ATPases Associated with various cellular Activities) family of protein unfoldases, which couple the chemical energy from nucleotide hydrolysis to mechanical work used in protein unfolding and quality control. Several studies demonstrate a role for TorA in regulating NE protein assembly though a mechanistic basis understanding of how TorA couples its ATPase activity to its cellular function is unclear. We have measured steady state ATPase activity of full-length TorA in the presence and absence of its cofactor LAP1 in *vitro*. We find that TorA does not need LAP1 to bind and hydrolyze ATP, in contrast to previous studies. In addition, the TorA-LAP1 interaction does not increase TorA ATPase activity at saturating ATP concentrations, but the interaction increases TorA ATP binding affinity. Our data define a novel role for LAP1 in regulating TorA ATPase activity and provide a framework for understanding how this enigmatic enzyme couples nucleotide binding and hydrolysis to mechanical work.

P377/B386

The Sun1 Splicing Variants Sun1_888 and Sun1_916 Differentially Regulate Nucleolar Structure.

M. Hieda, E. Satomi, M. Ueda; Ehime Prefectural University of Health Sciences, Ehime, JAPAN.

The nucleolar structure is highly dynamic and strictly regulated in response to internal cues, such as metabolic rates, as well as to external cues, such as mechanical forces applied to cells. Although the multi-layered nucleolar structure is largely determined by the liquid-like properties of RNA and proteins, the mechanisms regulating the morphology and number of nucleoli remain elusive. The linker of the nucleoskeleton and cytoskeleton (LINC) complex comprises inner nuclear membrane Sad1/UNC-84 (SUN) proteins and outer nuclear membrane-localized nesprins. We previously showed that depletion of SUN1 proteins affects nucleolar morphologies. This study focuses on the function of SUN1 splicing variants in determining nucleolar morphology because the functional differences among SUN1 splicing

variants remain unknown. An RNA interference strategy showed that the dominantly expressed variants, SUN1_888 and SUN1_916, were crucial for nucleolar morphology but functionally distinct. In contrast, depletion of nesprin-1 or nesprin-2 did not affect nucleolar morphology or numbers. In addition, depletion of either SUN1_888 or SUN1_916 altered the chromatin structure and affected the distribution of histone modifications. Based on these results, we propose a model in which the LINC complex plays a role in modulating nucleolar morphology and numbers via chromatin.

Destabilization of the Linc Complex Alters Spindle Orientation and Apico-basal Polarity in Glandular Epithelia.

V. Narayanan[1], Q. Zhang[2], T. Lele[2], D. Conway[1]; [1]Virginia Commonwealth University, Richmond, VA, [2]University of Florida, Gainesville, FL.

Destabilization of the LINC Complex Alters Spindle Orientation and Apico-basal Polarity in Glandular Epithelia Vani Narayanan[1], Qiao Zhang[2], Tanmay P. Lele[2], Daniel E. Conway[1] [1]Department of Biomedical Engineering, Virginia Commonwealth University, Richmond, VA, 23284 [2]Department of Chemical Engineering, University of Florida, Gainesville, FL 32611 the nuclear LINC (linker of the nucleoskeleton and cytoskeleton) complex, that serves as a bridge between the nuclear lamina and cytoskeleton, has recently emerged as another critical structure and mechanosensitive region of the cell. Mutations associated with the LINC complex components has its implications in cancer, but it remains unclear how cell-level changes translate into tissue-level malignancy. We hypothesized that decoupling the nucleus from the cytoskeleton would affect formation and homeostasis of the epithelium. To investigate the role of the LINC complex in epithelial cells, we developed an MDCK II cell line expressing inducible dominant negative (DN) KASH, a peptide that disrupts the endogenous nesprin-SUN interactions and blocks nuclear-cytoskeleton interactions. Phenol-free reduced growth factor reduced Matrigel™ (Corning) was used for all 3D cell-culture experiments. (DN) KASH induced acini exhibited asymmetric cell division over a period of 24 hours resulting in disrupted lumen morphology. Additionally, we observed that decoupling the nucleus from the cytoskeleton affected mitotic spindle orientation in 2D monolayers grown on transwell permeable supports and resulted in stratification when allowed to grow over an extended period of time. To investigate whether polarity disruption followed or preceded asymmetric cell division as a result of LINC disruption, the (DN) KASH induced acini were observed at varying time points post induction. An increase in altered polarity was observed over a period of 48, 72 hours and 7 days, respectively. To elucidate cellular proliferation, disruption in polarity and cell survival in the luminal space, LINC disrupted acini were studied for β1-integrin expression. Acinar lumenal filling was accompanied with increased expression of β1-integrin confirming altered polarity with LINC complex disruption and suggesting the possibility of an over-compensatory mechanism involving focal adhesions. Furthermore, blocking proliferation via aphidicolin (a reversible inhibitor of nuclear DNA replication) prevents lumen occlusion, indicating that cell division is required for acinar lumen collapse. Taken together, our results indicate that nucleo-cytoskeletal coupling is necessary for cells to sense, respond to mechanical cues and maintain normal cellular function on a tissue scale.

P379/B388

Determining the Regulatory Role of LINC Complex in Smad Signaling and in Expression of Inner Nuclear Membrane Protein MAN1 in the Presence of TGF-β.

I. Jalilian, E. Carley, R. Stewart, P. Lusk, M. King; Yale University, New Haven, CT.

Transforming growth factor (TGF)-β plays a central role in health and disease. The TGF-β pathway acts through Smads, a family of transcription factors that are activated by phosphorylation in the cytoplasm and translocate into the nucleus to modulate gene expression. Post-translational modifications, trafficking and functional regulation of Smads has been the subject of numerous studies. For instance, it has been shown that MAN1, an inner nuclear membrane specific protein, negatively regulates Smad-dependent TGF-β signaling. Our recent work demonstrated that SUN2, a component of the linker of nucleoskeleton and cytoskeleton (LINC) complex, influences Smad localization and gene regulation, suggesting that mechanical signals transmitted by LINC might also influence Smad signaling. Despite these studies, however, it remains to be elucidated how, in the presence of TGF-β, nuclear envelope (NE)-associated proteins and the LINC complex act together to regulate Smad signaling. In this study we provide new insight into how, in the presence of TGF-β1, the LINC complex affects localization of activated Smads (phosphoSmad2/3 and Smad4), the NE localization and total expression level of MAN1, and the expression of Smad target genes. Here we take advantage of primary wild types (WTs) and *Sun2*$^{-/-}$ mouse embryonic fibroblasts (MEFs). Cells, plated in conditions to engage their integrins (fibronectin-coated surfaces), were treated with TGF-β1 (10 ng/ml) for 45 minutes. Fluorescent microscopy demonstrates that, in response to TGF-β1, the nuclear translocation of activated Smads occurs in both the presence and absence of SUN2. However, in contrast to WTs, *Sun2*$^{-/-}$ MEFs show higher levels of nuclear phosphoSmad2/3 and Smad4 even in the absence of TGF-β1. We also observe an increase in the pool of MAN1 at the NE in both WTs and *Sun2*$^{-/-}$ MEFs after TGF-β1 stimulation, but this is more profound in *Sun2*$^{-/-}$ MEFs. Western blot analysis of MAN1 confirms that, in response to TGF-β1, expression of MAN1 increases in *Sun2*$^{-/-}$ MEFs compared to WT MEFs. Although the effect of these changes on gene expression in these model cell lines is still under investigation, our previous work suggests that Smads inefficiently regulate their target genes in *Sun2*$^{-/-}$ cells despite the elevated levels of nuclear Smads. Our results show that SUN2 plays a critical role in the expression and localization of MAN1, an established negative regulator of TGF-β signaling. Our data also suggest that, in addition to soluble factors, mechanotransduction through LINC complex influences the nuclear aspects of TGF-β and Smad signaling, likely through regulation of MAN1.

P380/B389

The Giant KASH Protein ANC-1 Functions with and Without LINC Complexes to Position Nuclei and Other Organelles.

H. Hao, S. Kalra, L. Jameson, L. Herrera, N. Cain, D. Starr; University California-Davis, Davis, CA.

Nesprin-1 and 2 are outer nuclear membrane KASH proteins that interact with SUN proteins to form Linker of nucleoskeleton and cytoskeleton (LINC) complexes to position nuclei. LINC is important for many cellular and developmental processes; defects in LINC lead to disease. We use the *C. elegans* hypodermis as a model because it contains 139 syncytial nuclei that are normally evenly spaced apart. In *C. elegans*, ANC-1 is an ortholog of Nesprin 1 and 2 that is over 8500 residues with a conserved N-terminal calponin homology (CH) domain that binds actin and a C-terminal KASH domain that interacts with SUN protein UNC-84. Mutations in *anc-1* or *unc-84* disrupt nuclear anchorage. In our working model, ANC-1 tethers nuclei to the actin cytoskeleton. However, our new genetic data do not fit with the model. First, *anc-1(null)* mutants have much more severe nuclear anchorage defects than *unc-84(null)* or *anc-1(Δkash)* mutants, suggesting an unknown, LINC-independent role of ANC-1. Second, CRISPR deletion of the N-terminal CH domains had no nuclear anchorage defects, indicating that a

shorter isoform, *anc-1b*, without the CH domain is sufficient to position nuclei in the hyp7. In support of this, early stop codons and RNAi targeted against the first 1500 residues of *anc-1* do not cause nuclear anchorage defects and we isolated a cDNA representing *anc-1b*. Interestingly, CRISPR-mediated deletion of the large repeats in the middle of ANC-1 or the N-terminal residues of ANC-1b caused severe nuclear anchorage defects, implicating an essential role for the cytoplasmic domains of ANC-1 in nuclear positioning. Using CRISPR editing, we show that GFP::ANC-1b localizes to the nuclear envelope and what appears to be the ER. In addition, mitochondria and lipid droplets are also mislocalized in *anc-1(null)* mutants. We hypothesize that the cytoplasmic domains of ANC-1 regulate the global cytoskeleton and *anc-1* mutants disrupt the positioning of nuclei, mitochondria, lipid droplets, and other organelles. Finally, deletion of both the transmembrane domain and the KASH domain caused significantly more severe nuclear anchorage defects compared with *anc-1(Δkash)*, indicating that targeting ANC-1 to membranes is important for its LINC-independent function. In summary, we propose a new role for the giant KASH protein ANC-1 in organizing the cytoplasm to position multiple organelles.

P381/B390

How FHOD1 Interacts with Nesprins to Mediate Nuclear Movementhow Fhod1 Interacts with Nesprins to Mediate Nuclear Movementhow Fhod1 Interacts with Nesprins to Mediate Nuclear Movementhow Fhod1 Interacts with Nesprins to Mediate Nuclear Movement.

R. S. M. Lim, V. E. Cruz, **T. U. Schwartz**; Massachusetts Institute of Technology, Cambridge, MA.

Linker of nucleoskeleton and cytoskeleton (LINC) complexes form bridges across the nuclear envelope to connect nucleoskeleton and cytoskeleton for force transmission. LINC complexes are composed of KASH proteins traversing the outer nuclear membrane, and SUN proteins crossing the inner nuclear membrane. While the SUN-KASH interaction is structurally understood in principle, neither tethering to the cytoskeleton nor the nucleoskeleton is resolved. Here we present the crystal structure of FHOD1 interacting with a specific spectrin repeat within Nesprin2. The structure reveals a novel type of engagement, including a highly conserved charge network. We were able to use the structural information to find at least one additional spectrin repeat that can also interact with FHOD1. With this data we can start to unravel the details of the engagement of the LINC complex with the actin cytoskeleton.

P382/B391

The KASH Protein UNC-83 Serves as a Cargo Adapter at the Nuclear Envelope for Microtubule Motors and Activates Kinesin-1.

E. Gregory[1], S. Niwa[2], K. Chiba[1], A. Paparella[1], R. McKenney[1], **D. Starr**[1]; [1]University California, Davis, CA, [2]Tohoku University, Sendai, JAPAN.

Many intracellular cargos move along microtubules using a combination of kinesin-1 and dynein motors. The *C. elegans* KASH protein UNC-83 is targeted to the outer nuclear membrane, where it serves as a cargo adapter to recruit both kinesin-1 and dynein motors to nuclei. Nuclei migrate towards the plus ends of microtubules using primarily kinesin-1 motors in *C. elegans* embryonic hyp7 cells. However, in *C. elegans* larval P cells, nuclei move toward the minus ends of microtubules, favoring dynein. It is unknown how nuclei regulate the decision between using kinesin-1 or dynein motors to move nuclei in opposite directions at different times in development. In our model, different isoforms of UNC-83, alternatively expressed in hyp7 or P cells, favor kinesin or dynein, respectively. Specifically, our previous

genetic data suggest that a short *unc-83c* isoform is sufficient for kinesin-driven nuclear migration in hyp7 cells, but a longer *unc-83a/b* isoform is required for dynein-driven movements in P cells. We hypothesize the short *unc-83c* isoform activates kinesin-1 and/or inhibits dynein, while the longer *unc-83a/b* isoform inhibits kinesin-1 and/or activates dynein. We are using a combination of in *vivo* developmental genetics and in *vitro* microtubule motor assays to test our model. Purified full-length kinesin-1/KLC-2 tetramers have no motor activity in our TIRF assays. However, the addition of the cytoplasmic domain of UNC-83c robustly activates kinesin-1 in our microtubule motor assays. To test the role of UNC-83c in *vivo,* we engineered a mutation using CRISPR/Cas9 into the EWD motif of UNC-83. EWD motifs are thought to mediate interactions with kinesin light chains. *unc-83(EWD-GSA)* mutant animals have a severe hyp7 nuclear migration defect, suggesting they are not capable of activating kinesin-1. We are currently using CRISPR/Cas9 genome editing to express *unc-83* isoforms in reciprocal tissues. We are deleting domains unique to *unc-83a/b in* P cells and adding the *unc-83a/b* unique regions under control of the *unc-83c* reporter in hyp7 cells. Our combination of in *vitro and* in *vivo* approaches is expected to shed light on the molecular mechanisms of how microtubule motors of opposite directionality are regulated on a single cargo.

***Drosophila* Emerins Control Linc Complex Localization and Transcription to Regulate Myonuclear Position.**

T. R. Mandigo, B. D. Turcich, A. J. An derson, M. R. Hussey, E. S. Folker; Boston College, Boston, MA.

Mispositioned nuclei are a hallmark of skeletal muscle disease. Although mispositioned nuclei have long been a recognized marker of ongoing muscle repair, recent data suggests a more complicated relationship. Sets of proteins have evolved, and are conserved throughout eukaryotes, to facilitate the transmission of force between the cytoplasm and the nucleus and enable nuclear movement. Intriguingly, many of the genes that encode these proteins are mutated in patients with the muscle disease Emery-Dreifuss muscular dystrophy (EDMD), suggesting that disruptions in nuclear movement and position may contribute to disease progression. Furthermore, the genes mutated in patients with EDMD regulate nuclear movement in various cell types suggesting that their function during nuclear movement has been conserved. Yet how these genes are coordinated to move nuclei is not known. Here we demonstrate that the disruption of EDMD-linked genes caused at least two distinct phenotypes. These different phenotypes are based in opposing effects on the amount of the KASH-domain protein Klarsicht that is localized to the nucleus. The levels of Klarsicht in the nuclear envelope are differentially affected by the opposing activities of two separate emerin proteins, Bocksbeutel and Otefin. When Bocksbeutel is disrupted, Klarsicht protein localization is disrupted and nuclei fail to separate from one another. When Otefin is disrupted, Klarsicht transcription is increased and nuclei separate into the center of the muscle fiber. Furthermore, loss of Otefin is able to rescue the nuclear positioning phenotypes caused by loss of Bocksbeutel. These data indicate that Klarsicht levels in the nuclear envelope are a critical determinant of nuclear position. Additionally, these levels are controlled by two opposing emerin activities that are divided between Bocksbeutel and Otefin.

Investigation of Actin Binding Domains of Nesprin.

R. Behler, J. Zahn, R. Volodarsky, X. Aura, S. Solmaz; Binghamton University, Vestal, NY.

Nuclear mechanotransduction is essential in a wide range of biological functions including nuclear movement, nuclear positioning, cell polarization, and chromatin organization. Genetic mutations of KASH family proteins, to which Nesprin 1 belongs cause human diseases including Emery-Dreifuss muscular dystrophy (EDMD). Nesprin 1 is a component of LINC complexes responsible for transferring nucleo-cytoskeletal forces, and recruits actin through its calponin homology domains. Here, we purified and characterized the actin-recruiting calponin homology domains of human Nesprin 1. Circular dichroism spectroscopy wavelength scans confirm that these domains are mostly alpha-helical. The formation of dimers and monomers was confirmed by multi-angle light scattering. The interaction of Nesprin 1 and actin was confirmed through actin co-sedimentation assays. Our data provide mechanistic insights into actin recruitment and bundling though the calponin homology domains of Nesprin 1.

P385/B394

Structural an alysis of Different Linc Complexes Reveals Distinct Binding Modes.

V. E. Cruz, E. F. Demircioglu, **T. U. Schwartz**; Massachusetts Institute of Technology, Cambridge, MA.

Linker of nucleoskeleton to cytoskeleton (LINC) complexes are molecular tethers that span the nuclear envelope (NE) and physically connect the nucleus to the cytoskeleton. LINC complexes are composed of KASH proteins traversing the outer nuclear membrane, and SUN proteins crossing the inner nuclear membrane. They mediate mechanical force transmission across the NE in processes such as nuclear anchorage, nuclear migration, and homologous chromosome pairing during meiosis. Humans have several SUN- and KASH-containing proteins, yet it is poorly understood what governs their proper engagement. To investigate this question, we solved high resolution crystal structures of human SUN2 in complex with the KASH-peptides of Nesprin3, Nesprin4, and KASH5. In comparison to the published structures of SUN2-KASH1/2 we observe alternative binding modes for these KASH peptides. While the core interactions between SUN and the C-terminal residues of the KASH peptide are similar in all five complexes, the extended KASH-peptide adopts at least three conformations. The much improved resolution of the new structures allows for a more detailed analysis of other elements critical for KASH interaction, including the KASH-lid and the cation loop region.

P386/B395

The Actin Binding Domain of Nesprin-2G Is Required for Lumen Formation in Mammary Epithelial Acini.

K. L. Mui[1], T. P. Lele[2], D. E. Conway[3], G. G. Gundersen[1]; [1]Columbia University, New York, NY, [2]University of Florida, Gainesville, FL, [3]Virginia Commonwealth University, Richmond, VA.

The linker of nucleoskeleton and cytoskeleton (LINC) complex connects the nucleus to the cytoskeleton and plays key roles in diverse aspects of cell behavior from positioning the nucleus to regulating cytoskeletal dynamics. The LINC complex is comprised of an outer nuclear membrane nesprin and an inner nuclear membrane SUN protein to form a complex in the perinuclear space through the binding of their KASH and SUN domains, respectively. Studies of the LINC complex have established roles for them in mesenchymal cells, but there are few studies examining them in epithelial cells. Previously, we

showed with dominant negative approaches that disrupting the LINC complex in 3D normal breast epithelia acini, prevented both the formation and maintenance of acini with hollow lumens (Zhang, Q. et al., Current Biology, 2019). Here, we used shRNA approaches to identify the specific LINC complexes involved. Knockdown of nesprin-2, SUN1 or SUN2, but not nesprin-1, prevented the formation of acini with hollow lumens, and concomitantly increased proliferation and apoptosis. Therefore, distinct components of the LINC complex are critical in the development and homeostasis of mammary epithelial tissue. To determine the specific cytoskeletal linkages that are involved in lumen formation, we next re-expressed different fragments of nesprin-2G in knockdown cells. While the N-terminal fragment of nesprin-2G bearing F-actin-binding calponin homology domains was sufficient to rescue lumen formation, the C-terminal fragment containing the microtubule-interacting domain failed to do so. These data show that nesprin-2G interaction with F-actin is required for 3D acini formation and a normal balance of proliferation and apoptosis in the acini. As actin anchors the nucleus in other systems, we hypothesize that disrupting nuclear anchorage may be required for normal acini formation.

P387/B396

Nuclear Size Changes Caused by Local Motion of Cell Boundaries Dilate Chromatin and Intranuclear Bodies.

A. Katiyar, V. J. Tocco, Y. Li, V. Aggarwal, R. B. Dickinson, T. P. Lele; University of Florida, GAINESVILLE, FL.

The mechanisms by which mammalian nuclear shape and size are established in cells, and become abnormal in disease states are not understood. Here, we tracked motile cells that underwent systematic changes in cell morphology as they moved from 1-D to 2-D micro-patterned adhesive domains. Motion of the cell boundaries during cell motility caused a dynamic and systematic change in nuclear volume. Short time scales (~ 1 h) distinguished the dilation of the nucleus from the familiar increase that occurs during the cell cycle. Nuclear volume was systematically different between cells cultured in 3D, 2D and 1-D environments. Dilation of the nuclear volume was accompanied by dilation of chromatin, a decrease in the number of folds in the nuclear lamina, and an increase in nucleolar volume. Treatment of 2D cells with non-muscle myosin-II inhibitors decreased cell volume, and proportionately caused a decrease in nuclear volume. These data suggest that nuclear size changes during cell migration may potentially impact gene expression through the modulation of intra-nuclear structure.

P388/B397

Cytoplasmic Volume and Limiting Nucleoplasmin Scale Nuclear Size during *Xenopus Laevis* Development by Altering Chromatin Organization.

P. Chen, M. Tomschik, K. Nelson, J. Oakey, J. C. Gatlin IV, D. L. Levy; University of Wyoming, Laramie, WY.

A basic question in cell biology is how the size of the nucleus is regulated with respect to cell size. During early *Xenopus laevis* embryogenesis, there are dramatic reductions in both cell and nuclear sizes. This reproducible scaling of nuclear size provides a robust system with which to characterize and identify mechanisms of nuclear size regulation. To test if the volume of embryonic cytoplasm is limiting for nuclear growth, we used microfluidic technology to encapsulate gastrula stage *X. laevis* extract and nuclei in droplets of defined volume and shape. We found that cytoplasmic volume and composition, but not cytoplasmic shape, contribute to nuclear size scaling. To identify cytoplasmic components limiting for nuclear growth, we biochemically fractionated *X. laevis* egg extract and identified the

histone chaperone nucleoplasmin (Npm2) as a putative nuclear size-scaling factor. Nuclear size increased in extract droplets supplemented with Npm2 protein, and embryos microinjected with Npm2 exhibited larger nuclei at gastrulation. Consistent with Npm2 being a nuclear-size scaling factor, per cell amounts of nuclear Npm2 and histone H2B decrease over development. Chromatin staining and micrococcal nuclease digestion assays showed that Npm2 increases chromatin compaction and nucleosome packing while decreasing the amount of euchromatin. We propose that Npm2 drives nuclear growth by altering chromatin organization. To further investigate how chromatin organization might influence nuclear size, we studied nuclei assembled de novo in *X. laevis* egg extract. Nuclei treated with DNase or MNase were still import-competent but failed to expand and properly localize lamins to the inner nuclear membrane, suggesting that nuclear import is not sufficient for nuclear growth. We are currently testing the model that chromatin stiffness produces intranuclear forces that contribute to nuclear growth. In summary, we propose that reductions in cell volume with concomitant decreases in the amounts of Npm2 and nuclear histones contribute to developmental nuclear size-scaling by affecting chromatin organization.

P389/B398

RanGAP Targeting to the Nuclear Envelope Is Essential for Development in *Drosophila*.

S. Chen, M. Lyanguzova, K. Plevock Haase, H. Lee, A. Arnaoutov, M. Dasso; National Institutes of Health, Bethesda, MD.

The Ran GTPase is critical for nuclear-cytoplasmic transport, nuclear envelope (NE) assembly, and mitotic spindle formation. These processes are driven by gradients of GTP-bound Ran (Ran-GTP) and GDP-bound Ran (Ran-GDP). During interphase, Ran's chromatin-bound nucleotide exchange factor, RCC1, maintains high levels of Ran-GTP within nuclei. Conversely, Ran's GTPase activating protein, RanGAP, resides in the cytoplasm and promotes Ran-GTP hydrolysis, so that Ran-GDP is predominant in the cytosol. In fungi, RanGAP is diffusely distributed throughout the cytosol. However, multicellular organisms localize RanGAP to the NE. In vertebrates, RanGAP becomes SUMOylated, facilitating its association to the nucleoporin RanBP2 on the cytoplasmic face of the nuclear pore complex (NPC).We used cultured mammalian cells and *Drosophila to* investigate the functional consequences of RanGAP localization in metazoans. We used CRISPR/Cas9 gene editing to mutate human RanGAP (hRanGAP) in DLD-1 cells, preventing its SUMOylation and NPC targeting. Surprisingly, this change had no impact on cell viability and caused no obvious perturbations of nuclear transport or mitosis. The mechanism of *Drosophila* RanGAP (dRanGAP) targeting at the nuclear envelope had not been reported. We found that while dRanGAP associates to the NPC through binding to dRanBP2, the targeting mechanism is distinct from mammals to the extent that it occured via a direct association between dRanGAP and dRanBP2 without involvement of SUMOylation. We identified the domains in both proteins that mediate their binding and used CRISPR/Cas9 gene editing to generate dRanBP2 mutants (dRanBP2^{short}) that abolish dRanGAP anchorage to NPCs through a 23-amino-acid deletion. Homozygous RanBP2^{short} mutants exhibited no apparent growth defects as larvae. However, they died as pupae without gas bubble expulsion or eversion of the cephalic complex. This developmental arrest was rescued by a direct fusion of dRanGAP to dRanBP2^{short}, indicating that recruitment of dRanGAP to dRanBP2 per se was necessary for the pupal ecdysis sequence during development.Collectively, our results indicate that while the localization of RanGAP to the NE is widely conserved in multicellular organisms, the targeting mechanisms are not. Further, we find a previously unreported requirement for this localization in critical

tissue developmental processes, and we are currently working to understand the precise molecular role of dRanBP2-dRanGAP interaction during metamorphosis.

Nuclear Lamina and Laminopathies

P390/B399

Erk1/2 Phosphorylation of FHOD Connects Signaling and Nuclear Positioning Alternations in Cardiomyopathy Caused by Lamin A/C Gene Mutations.

S. An toku, W. Wu, L. Joseph, J. P. Morrow, H. J. Worman, G. G. Gundersen, 10026; Columbia University Coll Phys & Surg, New York, NY.

Lamin a and C, encoded by *LMNA*, are components of the nuclear lamina and contribute to the physical and biochemical properties of the nucleus. Mutations in *LMNA* cause striated muscle diseases including muscular dystrophy and dilated cardiomyopathy with a high risk of cardiac sudden death. Expression of muscle disease-causing lamin a variants leads to upregulation of ERK1/2 activity in hearts of humans and mice and inhibition of ERK1/2 ameliorates disease symptoms in mice. In a fibroblast model system, expression of muscle disease-causing lamin a variants disrupts nuclear positioning. We now show that striated muscle cells from *Lmna*$^{H222P/H222P}$ mice, which mimic human myopathies caused by *LMNA* mutation, have mis-positioned nuclei. In binucleated cardiomyocytes, the two nuclei were closer in *Lmna*$^{H222P/H222P}$ mice than in wild type mice and were not equidistantly spaced. In multinucleated skeletal muscle fibers, peripheral nuclei were clustered in *Lmna*$^{H222P/H222P}$ mice in contrast to the equidistant distribution in wild type mice. Using a fibroblast model, we found that muscle disease-causing lamin a variants inhibit actin-dependent nuclear movement and increase ERK1/2 phosphorylation of FHOD1/3, members of the formin family of actin regulators that bind nesprin-2 and at least for FHOD1 play a role in nuclear movement. Phosphomimetic forms of FHOD1/3 failed to rescue defective nuclear movement in FHOD1-depleted fibroblasts, whereas unphosphorylatable forms rescued the nuclear movement defect in fibroblasts expressing a muscle disease-causing lamin a variant. ERK1/2 phosphorylation of FHOD1/3 inhibited their F-actin bundling activity without affecting their actin polymerization activity. Phosphorylation of FHOD3, the major isoform in cardiomyocytes, was increased in hearts from *Lmna*$^{H222P/H222P}$ mice and reduced in mice treated with drugs that inhibit ERK1/2. Our results identify FHOD1/3 as the link between upregulated ERK1/2 activity and nuclear mis-positioning in muscle disease caused by *LMNA* mutations. They further suggest that nuclear mis-positioning may contribute to cardiac and skeletal muscle pathology.

P391/B400

Different Impact of Emerin in Skeletal and Cardiac Muscles from *Lmna*$^{H222P/H222P}$ Double Mutant Mice.

E. Wada, M. Kato, K. Yamashita, H. Kokuba, Y. K. Hayashi; Tokyo Medical University, Tokyo, JAPAN.

Laminopathies are tissue-selective diseases that affect differently in organ systems. Mutations in nuclear envelope proteins, emerin (*EMD*) and lamin A/C (*LMNA*) genes, cause clinically indistinguishable myopathy called Emery-Dreifuss muscular dystrophy (EDMD) and limb-girdle muscular dystrophy. Several murine models for EDMD have been generated; however, emerin-null (Emd) mice do not show obvious skeletal and cardiac muscle phenotypes, and Lmna$^{H222P/H222P}$ mutant (H222P) mice show only a mild phenotype in skeletal muscle when they already have severe cardiomyopathy. Thus, the underlying molecular mechanism of myopathy due to nuclear envelopathy is still unclarified. We generated double

mutant (Emd-/-/Lmna$^{H222P/H222P}$; EH) mice to characterize muscle involvement and to elucidate roles of interactions between emerin and lamin A/C in skeletal and cardiac muscles. As H222P mice, EH mice grow normally and have breeding productivity. EH mice did not have morphological abnormalities in different organ systems, such as kidney, lung and reproductive organs; however, they showed gradual body weight loss after 18 weeks of age associated with progression of cardiomyopahty. EH mice showed severer muscle involvement compared with that of H222P mice which was an independent of cardiac involvement at 12 weeks of age. Nuclear abnormalities, reduced muscle fiber size and increased fibrosis were prominent in skeletal muscle from EH mice. Muscle phenotypes were aggravated in an age-dependent manner. Both H222P and EH mice had similar cardiac abnormalities at 30 weeks of age which indicates that emerin has been implicated to contribute to skeletal or cardiac muscle in a manner different to that of lamin A/C. Roles of emerin and lamin A/C in satellite cell function and regeneration of muscle fibers were also evaluated by cardiotoxin-induced muscle injury. Delayed increases in *Myog* and *Myh3* expression were seen in both H222P and EH mice; however, at day 7 after injury, the expression levels of those genes were similar with control and regenerated muscle fiber size was not different. EH mice showed the progression of muscular dystrophy before appearance of cardiac dysfunction similar to EDMD patients. These results indicate that EH mouse is a suitable model for studying skeletal muscle involvement, independent of cardiac function, and roles of interaction between emerin and lamin A/C in different tissues.

P392/B401

An Induced Pluripotent Stem Cell Model of *LMNA*-associated Dilated Cardiomyopathy to Study the Disease Pathogenesis.

M. Maurer[1,2], T. Kirby[2], L. Wallrath[3], I. Benjamin[4], E. McNally[5], J. Lammerding[1,2]; [1]Meinig School of Biomedical Engineering, Cornell University, Ithaca, NY, [2]Weill Institute for Cell and Molecular Biology, Ithaca, NY, [3]Department of Biochemistry, University of Iowa, Iowa City, IA, [4]Medical College of Wisconsin, Milwaukee, WI, [5]Feinberg School of Medicine, Northwestern Medicine, Chicago, IL.

The *LMNA* gene encodes the intermediate filament proteins Lamins a and C, which form the nuclear lamina: a meshwork inside of the inner nuclear membrane that gives the nucleus structural support and modulates the organization of chromatin and other nuclear proteins. *LMNA* mutations cause numerous diseases, termed laminopathies, including dilated cardiomyopathy (*LMNA*-DCM) and muscular dystrophies. *LMNA*-DCM involves dilation of the left ventricle and thinning of the ventricle walls, which weakens the heart. On the cellular level, *LMNA*-DCM and skeletal muscle laminopathies are characterized by structural defects resulting from mechanically weakened nuclei that cannot adequately respond to mechanical forces, and by disrupted signaling pathways; however, the precise molecular mechanisms underlying the disease pathology remain unknown. In vitro models of *LMNA*-DCM are lacking, because primary cardiomyocytes are challenging to isolate and short-lived in culture. Thus, we aimed to develop an induced pluripotent stem cell-derived cardiomyocyte (iPSC-CM) model with *LMNA*-DCM patient-derived cells to study the cellular pathology. We found that *LMNA*-DCM iPSC-CMs have increased nuclear deformities compared to healthy controls, including abnormal nuclear shape and nuclear envelope blebbing, recapitulating defects found in cardiac tissue of laminopathic models. Furthermore, using a nuclear rupture reporter system, in which a GFP is fused to a nuclear localization signal (NLS-GFP), we observed nuclear rupture in *LMNA*-DCM iPSC-CMs, indicated by NLS-GFP spilling into the cytoplasm. Nuclear rupture exposes nuclear material, including chromatin, to the cytoplasm and can cause DNA damage. Accordingly, we found that *LMNA*-DCM iPSC-CMs had increased levels of

γH2AX, a marker of double stranded DNA breaks. In conclusion, our work demonstrates that patient-derived iPSC-CMs serve as a valuable in vitro model of *LMNA*-DCM. Ongoing work is aimed at investigating the functional effects of disrupted nucleo-cytoskeletal force transmission and structural damage to nuclei, as well as altered signaling pathways and DNA damage, in hopes of finding potential treatment avenues for *LMNA*-DCM.

P393/B402

The Use of Emerin-null and EDMD-causing Emerin Mutant Myogenic Progenitors to Elucidate the EDMD Mechanism.

A. Iyer[1], J. Holaska[2]; [1]University of the Sciences, Philadelphia, PA, [2]Cooper Medical School of Rowan University, Camden, NJ.

Mutations in the gene encoding emerin (EMD) cause Emery-Dreifuss muscular dystrophy (EDMD1), an inherited disorder characterized by progressive skeletal muscle wasting, irregular heart rhythms and contractures of major tendons. Emerin is a ubiquitously expressed integral inner nuclear membrane protein. The skeletal muscle defects seen in EDMD are caused by failure of muscle stem cells to differentiate and regenerate the damaged muscle. However, the underlying mechanisms remain poorly understood. RNA-sequencing performed on differentiating wildtype (WT) and emerin-null ($EMD^{-/y}$) myogenic progenitors revealed 1,945 genes were differentially expressed during the transition from differentiation day 0 to day 1 (transcriptional reprograming for myogenic commitment) between WT cells and $EMD^{-/y}$ cells. Pathways enriched in differentially expressed genes were identified using multiple bioinformatics platforms. TGF-β, IGF-1, p38 and ERK MAPK, JAK-STAT, VEGF, FGF, YAP/TAZ, cell cycle, integrin signaling, stem cell differentiation, muscle development and growth hormone signaling pathways were highly enriched in differentially expressed genes. We created stable myogenic progenitors expressing WT emerin and each EDMD-causing missense emerin mutant in an $EMD^{-/y}$ background to test if these mutant progenitors exhibited impaired myogenic differentiation. We also posited similar transcriptional reprograming defects would be seen in the EDMD emerin mutants. Importantly, WT emerin expression rescued $EMD^{-/y}$ differentiation. All EDMD mutant myogenic progenitors failed to rescue $EMD^{-/y}$ myogenic differentiation. RNA-sequencing using the DNBseq platform was done during differentiation of $EMD^{-/y}$ progenitors expressing WT emerin and each EDMD-causing emerin mutant (S54F, Q133H and Δ9599) and a control emerin mutation (M179) to identify changes in the transcriptional program contributing to their impaired differentiation. We anticipate these studies will further refine the molecular pathways implicated in EDMD1, which will be confirmed using small molecule inhibitors or activators of these pathways.

P394/B403

Defining the Sun1 Protein Interactome in Muscle Differentiation.

M. Cook[1], A. Chojnowski[1], H. Werner[1], E. Wong[1], T. Nguyet[1], S. Winder[2], C. Stewart[1]; [1]IMB, A*STAR, Singapore, SINGAPORE, [2]The University of Sheffield, Sheffield, UNITED KINGDOM.

The nuclear lamina is composed of A- and B-type lamins, which are intermediate filaments that assemble into a complex, insoluble meshwork beneath the inner nuclear membrane (INM). This, together with other nuclear envelope (NE) proteins, have diverse functions in genome tethering, transcriptional regulation and nuclear positioning. The latter can be attributed to a NE-spanning group of proteins known as the LINC complex. INM SUN-domain proteins interact with their outer nuclear

membrane counterparts, KASH-domain proteins, in the perinuclear space. Together, the LINC assembly provides an uninterrupted mechanical connection anchoring the nuclear lamina to the cytoskeleton. Sun1 is crucial in several developmental processes as well as being implicated in muscle-wasting disorders both as a causative and disease modifying component. *Lmna*, encoding lamins a and C, is widely expressed in somatic cells, yet mutations give rise to a range of tissue-specific diseases, including muscular dystrophies, for reasons not fully understood. Interestingly, loss of Sun1 in *Lmna* mutant mouse lines suppresses many of the *Lmna*-associated disease phenotypes. One possible explanation is that the nucleoplasmic protein interactions of Sun1 change in a tissue-specific manner, in response to the *Lmna* mutation present, to elicit disease phenotypes. To elucidate the Sun1 protein interactome, we used 2C-BioID, a proximity biotinylation proteomics procedure. It improves on the original BioID method by using a two component (FKBP-FRB) system to both enhance the correct localisation of the fusion protein and reduce false positives acquired through non-specific biotinylation. Here, details of the validation of the 2C-BioID system, as well as an *ex vivo* study using a FRB-Sun1 bait during myoblast differentiation are presented.

P395/B404

Disrupting the Nesprin-1 KASH Domain Suppresses Pathology of Lamin A/C Loss in the Heart.

E. Leong, N. Khaing, E. S. M. Wong, W. Hong, **Y. Lee**, B. Burke, C. L. Stewart; Institute of Medical Biology, Singapore, SINGAPORE.

Mutations in the nuclear envelope (NE) proteins lamin A/C, encoded by *LMNA*, result in a variety of diseases, of which the most predominant is dilated cardiomyopathy (DCM). Among other NE proteins are the SUN and KASH domain proteins that form the LINC (Linker of Nucleoskeleton and Cytoskeleton) complexes. In the LINC complex, SUN-KASH domain interactions anchor 1 of 6 KASH domain proteins, including Nesprin-1, to the NE. In addition to *LMNA*, *SYNE1*, that encodes Nesprin-1, has been reported to be mutated in DCM. To investigate Nesprin-1 function, we used CRISPR/Cas9 to direct deletions to the 3' end of the murine *Syne1* gene, generating a frameshift mutation in the last coding exon of the KASH domain. As expected, in cells derived from homozygous *Syne1*^{Kfs} (KASH frameshift) mice, Nesprin-1 was dispersed from the NE. Consistent with another previously described *Syne1* mutant mouse line, but differing from 2 other independently derived lines, no obvious phenotypic defects were observed in our *Syne1*^{Kfs} homozygotes. To elucidate potential interactions between *Syne1* and *Lmna* in DCM, we crossed our *Syne1*^{Kfs} mice with *Lmna* mice where *Lmna* had either been globally deleted or where *Lmna* was inducibly ablated in cardiomyocytes. *Lmna* global knockout mice die within 3 weeks after birth but survive for up to 6 weeks on a homozygous *Syne1*^{Kfs} background. In contrast, loss of function of the closely related *Syne2* gene does not rescue global deletion of *Lmna*. In mice, in which tamoxifen-induced Cre/lox recombination resulted in deletion of *Lmna* in cardiomyocytes, death occurs within a month due to acute heart failure. On a homozygous *Syne1*^{Kfs} background, cardiomyocyte-specific *Lmna* null mice survive for at least 6 months following tamoxifen-induced deletion. This demonstrates that disrupting Nesprin-1-containing LINC complexes in cardiomyocytes ameliorates the pathological effects of the *Lmna* deletion. We propose that cytoskeletal forces transmitted by the LINC complex impinge on stress-sensitized *Lmna* mutant nuclei to cause DCM, and dispersal of these forces by mislocalization of Nesprin-1 relieves *Lmna* null nuclei from cytotoxic mechanical stress. We are investigating which cytoskeletal elements may contribute to this force transmission by immunofluorescence analysis to examine the NE localization of candidate proteins in *Syne1*^{Kfs} cardiomyocytes.

P396/B405

Defining Substrate Requirements for Cleavage of Farnesylated Prelamin a by the Integral Membrane Zinc Metalloprotease ZMPSTE24.

K. M. Wood[1], T. D. Babatz[1], E. D. Spear[1], O. W. Mossberg[1], K. Odinammadu[1], W. Xu[2], S. Michaelis[1]; [1]Johns Hopkins School of Medicine, Baltimore, MD, [2]Southern University of Science and Technology, Shenzhen, CHINA.

The zinc metalloprotease ZMPSTE24 is critical for human health. ZMPSTE24 mediates proteolytic maturation of prelamin A, the farnesylated precursor of the nuclear scaffold protein lamin A. Uncleaved, permanently farnesylated prelamin a accumulates when ZMPSTE24-dependent processing of prelamin a is disrupted by mutations in the genes encoding either the prelamin a substrate or the protease (*LMNA* or *ZMPSTE24,* respectively). This accumulation causes the premature aging disease Hutchinson Gilford Progeria Syndrome (HGPS) and other related progeroid disorders. Defective prelamin a cleavage may also play a role in physiological aging, since ZMPSTE24 activity may diminish as we age. ZMPSTE24 is an integral membrane protease with a novel structure, distinct from other membrane proteases. Its seven membrane spans form a hollow chamber enclosing an interior catalytic site with narrow side portals through which the substrate accesses the chamber. Interestingly, prelamin a is the only known mammalian substrate for ZMPSTE24; however, the basis of this specificity remains unclear. To define the requirements for recognition of farnesylated prelamin by ZMPSTE24, we used a humanized yeast system. We performed a comprehensive mutagenesis scan of the eight residues in prelamin a flanking the ZMPSTE24 cleavage site (TRSY/LLGN), mutating them to encode all other 19 possible residues. These studies allow us to generate a heatmap of cleavage efficiency that indicates the importance of residues in the P1' and P2' positions, just C-terminal to the cleavage site and begins to define a consensus motif with potential predictive value to identify other ZMPSTE24 substrates. In yeast, as in mammalian cells, the C-terminal 41 amino acids of prelamin a contain sufficient information for ZMPSTE24 cleavage. We have analyzed the 23-residue long region N-proximal to the cleavage site, as well as the 14 residues between the cleavage site and the farnesylated Cys, by generating a series of alanine substitutions, alanine additions, and deletions in prelamin A. This work indicates a surprising flexibility in the features required for recognition of prelamin a by ZMPSTE24. This flexibility must be reconciled with ZMPSTE24's selectivity for prelamin A. We expect that elucidating the substrate requirements of ZMPSTE24 could provide insight into integral membrane protease function and have valuable therapeutic implications for both progeroid disorders and healthy aging.

P397/B406

Role of E3 Ubiquitin Ligase RNF123 in Pathophysiology of Laminopathies.

R. Khanna; CSIR- Centre for Cellular and Molecular Biology, Hyderabad, INDIA.

Lamin A/C is a type V intermediate filament protein present underneath the inner nuclear membrane in metazoan cells and plays an important role in maintaining the structural integrity of the nuclear lamina. A-type lamins associate with the other nuclear proteins, such as lamin B1, emerin, retinoblastoma (pRb), PCNA, and lamina-associated polypeptide (LAP) 2α to perform essential nuclear functions, such as chromatin organization and tethering of heterochromatin to the nuclear periphery, cell cycle progression and differentiation, and effective DNA damage repair. Hence, mutations in metazoan nuclear lamina proteins, mainly lamin A/C cause rare tissue-specific genetic disorders, collectively termed as laminopathies. The hallmarks of laminopathic cells include increased nuclear fragility, DNA

damage, and defective cell differentiation. Here, we identified the upregulation of a RING domain-containing E3 ubiquitin ligase RNF123 in cells expressing laminopathic mutations. We also observed that RNF123 interacts with lamin a and lamin B1, and lamin-binding proteins, such as pRb, LAP2α, and emerin. Overexpression of RNF123 increased the proteasomal turnover of these nuclear proteins, an effect that was reversed upon the downregulation of this ligase. Increased proteasomal degradation of these nuclear proteins disturbs the homeostatic nuclear functions and possibly alters nuclear structure and function, thereby predisposing cells to fragile nuclei, increased DNA damage, and altered cell cycle kinetics. Laminopathic cells also show similar phenotypes, suggesting that increased ubiquitination and proteasomal turnover of nuclear proteins due to upregulation of E3 ligase RNF123 contributes to cellular pathophysiology observed in laminopathic cells.

P398/B407

Power Law Relationships in Expression Profiles Link Lamin-B to Proliferation and Poor Survival and Link Fibrosis to Prolonged Survival.

M. Vashisth, 19104, S. Cho, J. Irianto, Y. Xia, R. Wells, D. Discher; University of Pennsylvania, Philadelphia, PA.

Within organelles, cells, or tissues including tumors, spatiotemporal relationships between component molecules generally reflect principles that range from stoichiometric interactions or co-regulated genes to fractal organization. Such physico-chemical concepts are applied here in scaling analyses of key structural factors in the extracellular matrix and nucleus of liver, lung, and breast tumors in the Cancer Genome Atlas (TCGA) and in single cell RNA-Seq data. The nuclear filament LMNB1 exhibits systematic power laws with proliferation genes that are always high in tumors and predict poor survival. The strongest scaling is consistent with a lamina surrounding a rapidly replicating, fractal genome, and in *vitro* studies likewise show LMNB1 scales with and modulates cell cycle. The main fibrosis collagens *COL1A1 and COL1A2* also scale with each other, stoichiometrically, and with genes in a common fibrotic program across cancers. For liver tumors, the fibrotic genes surprisingly predict prolonged survival when liver tumors are more fibrotic than adjacent tissue. Basement membrane factors *COL4A1 and COL4A2* exhibit surface-to-volume type scaling with *COL1A1*, but noisy data generally frustrates such weak scaling. Single cell RNA-Seq data nonetheless exhibits scaling that underscores a simple means of validating expression data based on physicochemical principles.

P399/B408

How to Compartmentalize: the Role of Lamin C in Re-establishing Genome Organization After Cell Division.

V. Hoskins[1], X. Wong[2], T. Luperchio[1], M. Gordon[1], K. L. Reddy[1]; [1]Johns Hopkins University, SOM, BALTIMORE, MD, [2]Immunos, Singapore, SINGAPORE.

The contents of the eukaryotic nucleus are highly organized for functional efficiency. This can be seen on a variety of levels within the nucleus from protein-DNA hubs that perform particular roles, such as DNA damage repair, to higher organization of the chromatin itself. Recent studies using the chromosome conformation capture technique HiC have identified two types of 3D organization: areas of local self-interaction called topologically associated domains (TADs) and long-range genome-wide self-interactions that divide the genome into a (active) and B (inactive) compartments. Recently, we have shown that the B compartment and Lamin Associated Domains (LADs) represent the same functional

regions of the genome, including a shared sub-domain structure and boundaries. LADs are largely inactive regions of chromatin that are proximal to the meshwork of lamins that underlie the nuclear membrane and are marked by specific repressive histone modifications. Recently, we and others have demonstrated that, at the single cell level, LADs, along with TADs and A/B compartments are lost during mitosis and the chromosomes are reorganized and undergo large scale compaction. All genome organization is reestablished after mitosis during G1, but a great deal is still unknown about how this dynamic reorganization happens. Using the m6Atracer system, which allows us to image LADs in live cells, we have observed that LAD self-association occurs early in G1 prior to LAD establishment at the lamina. All of the LADs within a chromosome form 1-2 aggregates during early G1 and the nonLADs/A compartment of the chromosome form an exterior layer around these aggregates. These aggregates then make their way to the nuclear lamin over the course of several hours where they become anchored. How these aggregates are formed remains largely unknown but we have evidence showing that lamin C may be play a critical role in anchoring the LAD aggregates at the nuclear periphery.

P400/B409

Protein Kinase C Activity Alters Lamin B1 Dynamics Differently in Induced Pluripotent Stem Cells and Germ Layer Cells.

C. Wesley, D. Levy; University of Wyoming, Laramie, WY.

Cellular differentiation is fundamental to the growth and development of multicellular species. There are many changes in the composition of organelles and cellular structures during differentiation that are not well understood. We have been focusing on the nuclear lamina. While expression levels of lamins and lamina-associated proteins are known to vary in different tissues, the exact nature and possible significance of these changes during the differentiation process are not yet fully understood. In this study, we analyze some of the basic changes that occur in the nuclear lamina as human induced pluripotent stem cells (iPSCs) differentiate into cells of the three main germ cell layers. We have previously observed that the lamin B1 dynamics in each of these cell types vary significantly. In particular, iPSCs and mesoderm laminas have significantly higher lamin B1 dynamics than laminas of the endoderm or ectoderm, suggesting that there are innate structural differences in the laminas of these cells. To begin to address the mechanistic basis for these differences, we measured lamin B1 dynamics in response to altered PKC activity. We observed by lamin B1 FRAP analysis that PKC activation decreases the rate of fluorescence recovery in iPSCs by ~60% while PKC inhibition increases the rate of fluorescence recovery over 2.5-fold. Furthermore, PKC activation increases the total fluorescence recovery in mesoderm cells by ~10% while inhibition decreases total fluorescence recovery by ~30%. These data suggest that PKC-dependent nuclear lamin dynamics are altered in early differentiation. To address how these changes in lamin dynamics might affect the composition of the nuclear lamina, we are currently characterizing the lamin B1 interactome in stem and differentiated cells by co-immunoprecipitation and mass spectrometry.

P401/B410

Simplified Method for the Identification of Proteins, Rna and Dna at the Nuclear Envelope.

J. R. Tran; Carnegie Inst Washington, Baltimore, MD.

The nuclear lamina (NL) is a stable proteinaceous interface between the genome and the rest of the cell. This structure has garnered considerable interest due to the finding of diseases caused by NL

components and the lethal phenotype of most null animal models. Historically, the study of NL has proved difficult, partly due to the biochemical nature of the NL. This has led to a proliferation of surrogate methods that employ the proximity tagging strategy. Here, we describe a fast, robust and simplified method to identify proteins, RNA, and DNA associated with the NL. This method uses the Ascorbate Peroxidase (APEX) enzyme linked to Lamin B1. The discrimination between protein, RNA and DNA is based entirely on the application of RNase, DNase or protease after purification. We demonstrate that the method identifies many proteins previously known to be at the NL, in addition to new protein components. We show that RNA species associated with the NL are largely spliced and that association with the NL is related primarily to expression level. Finally, we show that lamina-associated domains (LADs) can be readily mapped and do not change with cell cycle stage. This simplified method should be a valuable tool for the study of the basic and medical aspects of the NL.

P402/B411

Emerin and Nuclear Structure of Invasive Breast Cancer Cells.

A. Liddane[1,2], I. Mercier[1], J. Holaska[2]; [1]University of the Sciences, Philadelphia, PA, [2]Cooper Medical School of Rowan University, Camden, NJ.

Dysmorphic nuclei are commonly used for diagnosis and prognosis of many different types of cancer. However, the underlying mechanism regulating these structural changes is poorly understood. It is becoming clear nuclear envelope proteins play an important role in regulating nuclear size and structure in cancer. Altered expression of nuclear lamins were found in many cancers and higher mean levels of lamins were associated with better clinical outcomes. The nucleus is the largest organelle in the cell with a diameter between 3-10 um. Nuclear size can greatly impact the cell's ability to migrate due to its large size and rigidity. Recent studies showed nuclear size, stiffness, and deformability is regulated by expression of nuclear envelope proteins, including emerin and other nuclear lamina proteins. Here we began to test emerin's role in nuclear size and stiffness and its effect one the invasiveness of breast cancer cells. Here we show the invasive breast cancer cell lines, MDA-231 and MDA-157 had a 1.4 to 1.7-fold smaller nuclei than normal breast tissue cells. These breast cancer cell lines had 1.4 to 1.8-fold decrease in emerin expression when compared to normal breast cells. Overexpression of emerin in invasive cancer cells increases nuclear size by 1.4-fold. Emerin expression also impairs their migration through 8 um pores. Emerin mutants that specifically inhibit binding to selected partners were tested for rescue in nuclear size and migration. Emerin mutants specifically disrupting binding to HDAC3, actin, or lamin a failed to rescue nuclear size. Emerin mutants specially disrupting binding to transcription regulators or BAF rescued nuclear size and migration. Thus, we concluded that interaction of emerin with the nucleoskeleton plays a significant role in regulating nuclear structure during cancer cell transformation, with chromatin interactions via HDAC3, surprisingly, also contributing to nuclear structure. These results align with previous studies showing both the lamins and chromatin contribute to nuclear structure. iRFP and GFP-EMD co-expressing cell lines were made to monitor metastases formation in mice. Each emerin mutant was co-expressed with iRFP to test if the functional interactions with the nucleoskeleton or chromatin (via HDAC3) is important for metastasis.

P403/B412

Histone Acetyltransferase Inhibition Rescues Emerin-null Myogenic Differentiation.

K. A. Bossone[1,2], J. A. Ellis[1,2], J. M. Holaska[2]; [1]University of the Sciences, Philadelphia, PA, [2]Cooper Medical School of Rowan University, Camden, NJ.

Emery-Dreifuss Muscular Dystrophy (EDMD) is a disease characterized by skeletal muscle wasting, contractures of major tendons, and cardiac conduction defects. Compromised skeletal muscle regeneration is predicted to result from impaired muscle stem cell differentiation. Mutations in the gene encoding emerin cause EDMD1. We previously showed emerin-null myogenic progenitors fail to properly exit the cell cycle, exhibit decreased myosin heavy chain expression, and have decreased myotube formation. Treatment with theophylline, a HDAC3 activator, rescued myotube formation in differentiating emerin-null myogenic progenitors. This suggested emerin activation of HDAC3 activity to reduce H4K5 acetylation is important for myogenic differentiation. Pharmacological inhibitors of histone acetyltransferases targeting acetylated H4K5 (Nu9056, L002) were used to test if the increased acetylated H4K5 was responsible for inhibiting emerin-null myogenic differentiation. Nu9056 and L002 rescued emerin-null myogenic progenitor differentiation. Treatment with SRT1720, which targets the NAD^+-dependent deacetylase SIRT1, showed no significant change in myotube formation. Thus, we conclude emerin regulation of HDAC3 activity to affect H4K5 acetylation dynamics is important for myogenic differentiation. Targeting H4K5ac dynamics represents a new strategy for ameliorating the skeletal muscle wasting seen in EDMD. The widely used COPD drug theophylline, which activates HDAC3 and rescues emerin-null differentiation, is a prime candidate for future testing.

P404/B413

Rescue of DNA Damage After Constricted Migration Reveals a Mechano-regulated Threshold for Cell Cycle.

C. R. Pfeifer, Y. Xia, K. Zhu, J. Irianto, D. Liu, K. Pannell, E. J. Chen, L. J. Dooling, M. P. Tobin, M. Wang, I. L. Ivanovska, L. R. Smith, R. A. Greenberg, D. E. Discher; University of Pennsylvania, Philadelphia, PA.

Migration through 3D constrictions can cause nuclear rupture and mis-localization of nuclear proteins, but damage to DNA remains uncertain as does any effect on cell cycle. Here, myosin-II inhibition rescues rupture and partially rescues the DNA damage marker γH2AX, but an apparent block in cell cycle appears unaffected. Co-overexpression of multiple DNA repair factors or antioxidant inhibition of break formation also exert partial effects, independent of rupture. Combined treatments completely rescue cell cycle suppression by DNA damage, revealing a sigmoidal dependence of cell cycle on excess DNA damage. Migration through custom-etched pores yields the same damage threshold, with ~4μm pores causing intermediate levels of both damage and cell cycle suppression. High curvature that is rapidly imposed by pores, probes, or small micronuclei consistently associates nuclear rupture with near-instantaneous dilution of lamin-B, whereas dilution of lamin-A is time-dependent, consistent with lamin-A's proposed viscous properties. Lamina dilution associates with nuclear rupture based on entry from cytoplasm of chromatin-binding cGAS (cyclic-GMP-AMP-synthase) as well as loss of repair factors. The cell cycle block caused by constricted migration is nonetheless reversible, with a potential for DNA mis-repair and genome variation.

P405/B414

Mutant Lamins Cause Nuclear Envelope Rupture and DNA Damage in Skeletal Muscle Cells.

T. Kirby[1], A. Earle[1], G. Fedorchak[1], P. Isermann[1], J. Patel[1], S. Iruvanti[1], S. Moore[2], G. Bonne[3], L. Wallrath[2], J. Lammerding[1]; [1]Cornell University, Ithaca, NY, [2]University of Iowa, Iowa City, IA, [3]Sorbonne Université, Center of Research in Myology, Association Institute of Myology, Paris, FRANCE.

Mutations in the human *LMNA* gene, which encodes the nuclear envelope proteins lamins a and C, cause autosomal dominant Emery-Dreifuss muscular dystrophy, congenital muscular dystrophy, limb-girdle muscular dystrophy, and other diseases collectively known as laminopathies. The molecular mechanisms responsible for these diseases remain incompletely understood, but the muscle-specific defects suggest that mutations may render nuclei more susceptible to mechanical stress. Using three mouse models of muscle laminopathies, we found that *Lmna* mutations caused extensive nuclear envelope damage, consisting of chromatin protrusions and transient rupture of the nuclear envelope, in skeletal muscle cells *in vitro* and in *vivo*. The nuclear envelope damage was associated with progressive DNA damage, activation of DNA damage response pathways, and reduced viability. Intriguingly, nuclear envelope damage resulted from nuclear movement in maturing skeletal muscle cells, rather than actomyosin contractility, and the nuclear damage was reversed by either depletion of kinesin-1 or disruption of the Linker of Nucleoskeleton and Cytoskeleton (LINC) complex. Depletion of kinesin-1 or LINC complex disruption reduced DNA damage, indicating that DNA damage is the result of nuclear envelope damage. Furthermore, LINC complex disruption rescued myofiber function and viability, indicating that the myofiber dysfunction is the result of mechanically induced nuclear envelope damage. The extent of nuclear envelope damage and DNA damage in the different *Lmna* mouse models strongly correlated with the disease onset and severity in *vivo*, and inducing DNA damage in wild-type muscle cells was sufficient to phenocopy the reduced cell viability of lamin A/C-deficient muscle cells, suggesting a causative role of DNA damage in disease pathogenesis. Corroborating the mouse model data, muscle biopsies from patients with *LMNA* associated muscular dystrophy similarly revealed significant DNA damage compared to age-matched controls, particularly in severe cases of the disease. Taken together, these findings point to a new and important role of nuclear envelope rupture and DNA damage as pathogenic contributors for these skeletal muscle diseases.

P406/B415

Rescue of Migration-induced Nuclear Rupture by Myosin-II Inhibition Depends on Lamin-A.

M. P. Tobin, C. R. Pfeifer, D. E. Discher; University of Pennsylvania, Philadelphia, PA.

During tumor growth and metastasis, cancer cells squeeze through micron-sized pores, invade basement membrane barriers, and enter blood capillaries. Such migration through rigid micropores has been shown to cause nuclear lamina and envelope rupture, which may result in increased DNA damage due to mis-localization of DNA repair factors. Reduction of actomyosin force can rescue migration-induced nuclear rupture, but it remains unclear whether this rescue depends on levels of lamin-A, a main nucleoskeletal protein which stiffens and strengthens the nucleus but is down-regulated in multiple cancers, including lung and breast cancers. Given that lamin-A suppression down-regulates actomyosin contractility but can also increase migration rate of the softer nuclei, we investigated whether lamin-A levels modulate the potential effects of actomyosin inhibition on nuclear rupture in constricted migration. Here, wild-type (WT) and lamin-A knockdown (KD) U2OS human osteosarcoma cells were migrated through 3 μm or 8 μm pores. Compared to WT, lamin-A KD cells exhibited much less nuclear

envelope rupture—as indicated by nuclear bleb formation—after 3 μm pore migration. Meanwhile, myosin-II inhibition *via* blebbistatin reduced migration-induced nuclear rupture among both WT and lamin-A KD cells; however, the fold-decrease in nuclear rupture was lower for KD versus WT. Thus, when lamin-A is knocked down, myosin-II inhibition only partially rescues migration-induced rupture, suggesting that lamin-A might play a role in the rescue mechanism. The results imply that tumors with low lamin-A (e.g. lung and breast) will not show more nuclear rupture and more damage in *in vivo* migration, and that recent reports of higher DNA damage in model tumors with low lamin-A could reflect nuclear rupture because of a stiff microenvironment.

P407/B416

Dyt1 Dystonia Patient-derived Fibroblasts Have Increased Deformability and Susceptibility to Damage by Mechanical Forces.

N. K. Gill[1], C. Ly[1], P. H. Kim[1], C. A. Saunders[2], L. G. Fong[1], S. G. Young[1], A. C. Rowat[1], **G. Luxton**[2]; [1]University of California, Los an geles, Los an geles, CA, [2]University of Minnesota, Minneapolis, MN.

DYT1 dystonia is a neurological movement disorder that is caused by a loss-of-function mutation in the *DYT1*/*TOR1A*gene, which encodes torsinA, a conserved luminal ATPases-associated with various cellular activities (AAA+) protein. TorsinA is required for the assembly of functional linker of nucleoskeleton and cytoskeleton (LINC) complexes, and consequently the mechanical integration of the nucleus and the cytoskeleton. Despite the potential implications of altered mechanobiology in dystonia pathogenesis, the role of torsinA in regulating cellular mechanical phenotype, or mechanotype, in DYT1 dystonia remains unknown. Here, we define the deformability of mouse fibroblasts lacking functional torsinA as well as human fibroblasts isolated from DYT1 dystonia patients. We find that the deletion of torsinA or the expression of torsinA containing the DYT1 dystonia-causing ΔE302/303 (ΔE) mutation results in more deformable cells. We observe a similar increased deformability of mouse fibroblasts that lack lamina-associated polypeptide 1 (LAP1), which interacts with and stimulates the ATPase activity of torsinA in *vitro*, as well as with the absence of the LINC complex proteins, Sad1/UNC-84 1 (SUN1) and SUN2, lamin A/C, or lamin B1. Consistent with these findings, we also determine that DYT1 dystonia patient-derived fibroblasts are more compliant than fibroblasts isolated from unafflicted individuals. DYT1 dystonia patient-derived fibroblasts also exhibit increased nuclear strain and decreased viability following mechanical stretch. Taken together, our results establish the foundation for future mechanistic studies of the role of cellular mechanotype and LINC-dependent nuclear-cytoskeletal coupling in regulating cell survival following exposure to mechanical stresses.

The Exocyst Complex Is Required to Maintain Mammalian Nuclear Architecture.

L. E. Adams, B. K. Dean, C. Horton, I. Jourdain, H. R. Dawe; University of Exeter, Exeter, UNITED KINGDOM.

The highly-conserved exocyst complex plays key roles in vesicle transport and establishment of polarity. It predominantly localises to sites of active cell growth. However, there is emerging evidence that the exocyst functions in other cellular contexts. Here, we show that the exocyst is also present in the nucleus, where it influences multiple aspects of nuclear architecture. The exocyst exhibits both perinuclear and nucleoplasmic localisations in mammalian cells by immunofluorescence. Further investigation by immuno-electron microscopy reveals that exocyst members localise to both the inner

and outer faces of the nuclear envelope, as well as to electron-dense regions within the nucleoplasm. GFP-TRAP analysis of multiple exocyst subunits identifies potential interactions with proteins of the inner nuclear envelope and nuclear lamina, further reinforcing the idea of a nuclear function of the exocyst. To investigate the nuclear effects of reduction of the exocyst, we used both CRISPR-mediated gene editing and siRNA against three individual exocyst subunits. Reduction in exocyst protein expression results in abnormal nuclear morphology, and disrupted organisation of the inner nuclear envelope and lamina. We demonstrate by immunofluorescence and electron microscopy that heterochromatin distribution is also altered. We conclude that the exocyst is required for correct nuclear architecture, and that this role likely has wider implications for gene expression and DNA repair.

Mechanobiology of Endocytic Vesicle Formation an alyzed by Sla2 Force Sensors.

M. Abella, L. An druck, G. Malengo, M. Skruzny; Max Planck Institute for Terrestrial Microbiology, Marburg, GERMANY.

Mechanical forces exerted by multiprotein machines are indispensable for many vital cellular processes. One of the best-studied examples is membrane reshaping during clathrin-mediated endocytosis, a principal vesicle trafficking route responsible for molecular uptake, signaling, and membrane homeostasis. During endocytosis, a small region of the plasma membrane reshapes from a flat sheet to a closed vesicle. This reshaping requires mechanical force, which is provided by multiple endocytic proteins and actin polymerization. Several theoretical models have been already proposed to describe force requirements during endocytosis (Lacy et al., 2018). However, to mechanistically understand force-dependent endocytic vesicle formation, applied forces need to be analyzed in vivo to report real force values and to delineate roles of involved proteins, and physical constraints.To achieve that, we used FRET (Förster Resonance Energy Transfer) tension sensors (Freikamp et al., 2016), which allow the measurement of pN forces in vivo, and inserted them into the yeast Hip1R protein Sla2. Sla2 is part of the essential Sla2-Ent1 (Hip1R- epsin 1-3 in human) protein linker transmitting force of polymerizing actin cytoskeleton to the plasma membrane (Skruzny et al., 2012, 2015). We followed forces transmitted over Sla2 in real time by measuring FRET changes of Sla2 force sensors during individual endocytic events. Using sensors of different force sensitivity, we estimated the maximal force applied on Sla2 to be higher than 9 pN. Next, we analyzed the role of individual endocytic factors and physical cues in force-dependent steps of endocytosis. We increased the size of the actin meshwork at the endocytic site by deleting the negative WASp regulator Bbc1, which caused the lessening of the force transmitted prior to vesicle scission. We also counteracted the high turgor pressure of yeast cytoplasm by increasing the medium osmolarity and observed an overall decrease in the force required for membrane invagination. Finally, current experiments monitor endocytic force requirements under conditions of altered plasma membrane tension and temperature. We believe that our data will form a base of comprehensive, experimental-based biomechanical model of endocytic vesicle formation, which could be also highly valuable for understanding of other force-dependent membrane reshaping processes in the cell.

Complimentary Action of ENTH and IDP Domains in Epsin Supports Clathrin-mediated Endocytosis in High Membrane Tension Condition.

J. G. Joseph, V. Yee, A. P. Liu; University of Michigan, an n Arbor, MI.

Cells live in and adapt to constantly changing physical environment and how changes in membrane tension regulate various cellular processes is a fundamentally important question. Epsin is an adaptor protein in clathrin-mediated endocytosis that aids in membrane bending. Two main domains in epsin, a N-terminal ENTH (epsin N-terminal homology) domain and a C-terminal IDP (intrinsically disordered protein) domain, have been shown to promote membrane bending via two distinct molecular mechanisms. ENTH domain insert its H0 alpha helix into the lipid bilayer to initiate membrane curvature while IDP domain causes membrane bending via steric repulsion. In this present work, we show that cells treated with a hypo-osmotic solution to increase membrane tension show an increase fraction of short-lived CCPs, suggesting a defect in clathrin assembly. However, overexpressing epsin rescues the stability of CCPs under hypo-osmotic shock. The recruitment of epsin increases in CCPs with elevated membrane tension by either increasing the area of cell spreading or by osmotic shock. Epsin gets recruited prior to clathrin to CCP nucleation sites and reaches the tension dependent maxima before clathrin assembly. However, masking the N-terminus of ENTH with EGFP or deletion of ENTH in epsin, delays recruitment of epsin to CCP nucleation site. Cells expressing ENTH-deleted epsin no longer have elevated recruitment of epsin at high tension. Moreover, the removal of H0 alpha helix in ENTH is responsible for the loss of tension sensitivity. ENTH domain, while necessary for tension sensitivity of epsin is not necessary for epsin puncta formation. However, deletion of AP2 binding and clathrin binding sites in IDP domain renders epsin cytosolic and without the ability to recruit to membrane. Further, IDP domain itself is sufficient for increasing stability of CCPs as expressing the IDP domain of epsin reduces the population of short-lived pits when recruited to CCPs. We conclude that H0 alpha helix in ENTH domain of epsin acts as a tension sensor and IDP domain acts as a tether stabilizing CCP complex. Our work reveals the complimentary action of ENTH and IDP domains of epsin allow it to support CME in high tension conditions.

P411/B421

ESCRT-dependent Protein Sorting Is Required for the Viability of Clathrin-mediated Endocytosis Mutants and the Maintenance of Plasma Membrane Protein Composition.

K. Hoban, S. Y. Lux, J. Poprawski, Y. Zhang, J. Shepherdson, P. Castiñeira, S. Pesari, D. C. Prosser, C. Norris, B. Wendland; Johns Hopkins University, Baltimore, MD.

Endocytic trafficking from the plasma membrane (PM) regulates many processes, including lipid and protein turnover, signaling, and nutrient uptake. During clathrin-mediated endocytosis (CME), adaptors bind to cytoplasmic regions of transmembrane cargo proteins, and many of these endocytic adaptors are also directly involved in the recruitment of clathrin. This clathrin-associated sorting protein family of adaptors includes the yeast epsins, Ent1/2, and AP180/PICALM homologues, Yap1801/2. Mutant strains lacking these four adaptors, but expressing a single epsin N-terminal homology (ENTH) domain necessary for viability (4Δ+ENTH), exhibit endocytic defects, such as cargo accumulation at the plasma membrane (PM). This CME-deficient strain provides a sensitized background ideal for revealing cellular components that interact with clathrin adaptors. We performed a mutagenic screen to identify alleles that are lethal in 4Δ+ENTH cells, a genetic interaction known as synthetic lethality, using a colony-

sectoring reporter assay. After isolating candidate synthetic lethal genes by complementation, we confirmed that mutations in *VPS4* lead to inviability of a 4Δ+ENTH strain. Vps4 mediates the final step of endosomal sorting complex required for transport (ESCRT)-dependent trafficking, and we found that multiple ESCRT components are also essential in 4Δ+ENTH cells, including Snf7, Snf8, and Vps36. Deletion of *VPS4* from an *end3*Δ strain, another CME mutant, similarly resulted in inviability, and upregulation of a clathrin-independent endocytosis pathway rescued 4Δ+ENTH *vps4*Δ cells. Loss of Vps4 from an otherwise wild-type background caused multiple cargoes to accumulate at the PM due to an increase in Rcy1-dependent recycling of internalized proteins to the cell surface. Additionally, *vps4*Δ *rcy1*Δ mutants exhibited deleterious growth phenotypes. Together, our findings reveal the previously unappreciated effects of disrupted ESCRT-dependent trafficking on endocytic recycling and the PM.

Unveiling the Dynamics of Intracellular Neonatal Fc Receptor-ligand Interactions in Primary Macrophages by Fluorescence Fluctuation Spectroscopy (FFS) and FLIM-FRET Microscopy.

A. Pannek[1], A. M. Verhagen[2], S. K. Dower[2], E. Hinde[1], P. A. Gleeson[1]; [1]The Department of Biochemistry and Molecular Biology, Bio21 Molecular Science and Biotechnology Institute, the University of Melbourne, Melbourne, AUSTRALIA, [2]CSL Limited, Research, Bio21 Molecular Science and Biotechnology Institute, Melbourne, AUSTRALIA.

The neonatal Fc receptor (FcRn) is an MHC class I-like molecule expressed in several tissues, which interacts with the serum proteins IgG and albumin. FcRn binds endocytosed IgG and FcRn in a pH-dependent manner within intracellular endosomes. The ability to interact with FcRn under acidic conditions allows the sorting of IgG and albumin into endosomal recycling pathways and contributes to their high serum concentrations and uniquely long half-life. However, the molecular basis of the underlying trafficking events in the FcRn-dependent recycling system, especially for albumin, have yet to be resolved. Recent studies by our laboratory suggest that tubular transport carriers emerging from newly formed macropinosomes mediate a fast, FcRn-dependent recycling of albumin in bone marrow-derived macrophages (BMDMs). To characterize the intracellular interaction between albumin and FcRn in living cells and resolve the spatiotemporal dynamics of the albumin-FcRn recycling system in BMDMs, a multiplexed biophysical approach to fluorescent microscopy was established. Fluorescence fluctuation spectroscopy (FFS) of single fluorescent-labelled albumin molecules revealed a higher fraction of immobile albumin molecules within endosomal structures in the presence of FcRn compared to FcRn KO macrophages. To investigate the intracellular distribution of this interaction, the binding of a FcRn-mCherry fusion protein with A488-labelled albumin was spatially mapped using the phasor approach to FLIM-FRET. The presence of the FcRn fusion protein leads to a significantly reduced fluorescent lifetime of Alexa488-albumin molecules (2.5 ns) when compared to the absence of FcRn (3.3 ns). A FLIM-FRET time course following endocytosis of Alexa488-albumin demonstrated a gradual increase in the fraction of albumin molecules undergoing FRET from 20% to 70% during the first 15 minutes after endocytosis. Furthermore, this increase in FRET – which indicated high albumin-FcRn interaction – was observed within tubular transport carriers emanating from endosomal compartments. Collectively, these data unveil the spatiotemporal kinetics of FcRn-ligand binding and recycling. The approaches used give novel insights into the highly dynamic trafficking of albumin and FcRn within endosomal structures and also have wide applicability for the investigation of other intracellular ligand-receptor interactions.

P413/B423

Caveolae Stabilization by Ehd2 Is a Crucial Factor in Lipid Uptake and Obesity.

C. Matthäus[1], I. Lahmann[1], S. Kunz[1], W. Jonas[2], A. Schürmann[2], C. Birchmeier[1], O. Daumke[1]; [1]Max-Delbrueck-Centrum Fuer Molekulare Medizin, Berlin, GERMANY, [2]Experimental Diabetology, German Institute of Human Nutrition, Potsdam, GERMANY.

Caveolae are membrane invaginations of 50 - 80 nm in size that are ubiquitously found in endothelial cells, adipocytes or fibroblasts. In addition to their function in transporting molecules across the cell membrane, caveolae are also involved in lipid metabolism, signal transduction and mechanoprotection. Besides caveolin and the cavin protein families, the dynamin-related ATPase Eps15 homology domain-containing protein 2 (EHD2) localizes to caveolae, particularly to their necks, therefore attaching them to the membrane. By combination of electron microscopy and tomography and TIRF imaging, we found that loss of EHD2 in vivo resulted in increased detachment and mobility of caveolae in adipocytes or fibroblasts. Furthermore, we found an increased fatty acid uptake and consequently enlarged lipid droplets in cells and tissue lacking EHD2. Detailed analysis of the fatty acid uptake mechanism revealed an involvement of the fatty acid transporter CD36 that partially localizes within the caveolar membrane structures. Obese patients and obesity mouse models further revealed downregulation of EHD2 and consequently increased detachment of caveolae from the plasma membrane. In summary, the observed results suggest that the EHD2-dependent stability of caveolae to the plasma membrane is a crucial factor in cellular lipid uptake.

P414/B424

A New Approach to Reconstruct Dynamics from Static Super-Resolution Images Reveals Structural Rearrangements of Proteins during Endocytosis.

P. Hoess[1], Y. Wu[1], M. Mund[2], J. Deschamps[1], M. Kaksonen[2], J. Ries[1]; [1]Cell Biology & Biophysics Unit, European Molecular Biology Laboratory, Heidelberg, GERMANY, [2]Department of Biochemistry, University of Geneva, Geneva, SWITZERLAND.

Clathrin-mediated endocytosis (CME) is a crucial cellular pathway that is involved in the uptake of molecules, membrane homeostasis and regulation of signalling. Budding yeast is a well-established model organism to study CME because of its easy genetics and the regular progression of CME. During CME in yeast, a protein machinery comprising more than 50 different proteins drives the invagination of the plasma membrane. One important part of the machinery is the actin network which provides the force for membrane invagination against the turgor pressure. Currently, the field is beginning to understand the architecture of the actin network and the function of its individual proteins involved in force generation. However, for example the nanoscale movement and orientation of the actin filaments is not fully understood and the mechanism by which actin crosslinkers function is postulated from modeling. To further elucidate the mechanisms of force generation we want to determine the spatial distribution of different endocytic proteins during membrane ingression with 10-20 nm resolution by dual-color high-throughput single-molecule localization microscopy (SMLM). The high resolution reached by SMLM requires acquisition times of several minutes which is why the cells have to be fixed prior to imaging. The fixation stops each endocytic site at a random time point along the endocytic timeline, hence dynamic information is lost. To overcome this problem, we developed an algorithm to reconstruct the endocytic time points of individual static snapshots by correlating them to temporally resolved data from living cells. For this we image the protein of interest in one color alongside with a

reference structure in a second color. We then use multi-dimensional features of this reference structure like height and intensity distribution to sort the individual snapshots temporally and align them spatially. We then calculate a running average of the sorted snapshots and combine different datasets to visualize the rearrangement of the different proteins. We have first results showing that our approach is able to spatially align the individual snapshots and sort them temporally based on geometric features of the reference structure. In a next step we are working on reproducing rearrangements of proteins of interest known from live-cell and electron microscopy. Finally, we will reconstruct the nanoscale rearrangement of key proteins of the endocytic machinery.

P415/B425

Metabolic Regulation of Adherens Junction Protein Trafficking in Rab11a Recycling Endosomes.

P. Gajwani, L. Wang, A. Ray, P. Toth, A. Karginov, J. Rehman; University of Illinois, College of Medicine, Chicago, IL.

Background: Vascular injury disrupts endothelial adherens junctions (AJs), which leads to increased vascular permeability, fluid accumulation in tissues and the influx of inflammatory cells. Following injury induced by inflammation or by other AJ-disrupting stressors, selected AJ proteins such as VE-cadherin and β-catenin are internalized and subsequently recycled back to the surface, thus restoring an intact barrier. Several mechanistic mediators of AJ recycling and trafficking have been identified but little is known about the metabolic regulation of this process. We recently identified the glycolysis regulatory enzyme PFKFB3 as an essential mediator of the endothelial response to injury. Here, we examine the role of PFKFB3 in regulating subcellular ATP production and its role in the trafficking of adherens junction proteins during acute injury as well as during its resolution. **Methods and Results:** to determine whether PFKFB3 regulated endothelial barrier restoration, we performed a transendothelial electrical resistance (TER) assay using Human Lung Microvascular Endothelial Cells (HLMVECs). PFKFB3 inhibition led to a 91% reduction in the rate of recovery following permeability induced by calcium chelation ($p<0.0001$), a non-inflammatory means of disrupting AJ integrity. Inhibition of PFKFB3 also markedly reduced surface levels of VE-cadherin following injury, indicating a key role of glycolysis in regulating the trafficking of VE-cadherin. Surprisingly, PFKFB3 inhibition did not affect the interaction between VE-cadherin and β-catenin as assessed by a proximity ligation assay, nor did it appear to affect the localization of these complexes at the cell junctions. We thus hypothesized that AJ proteins are trafficked to the plasma membrane in endocytic vesicles but are unable to fuse with the plasma membrane due to reduced regional ATP levels. In support of this hypothesis, we found that forced membrane targeting of PFKFB3 led to a 10% increase in ATP levels at the cell membrane ($p<0.005$), and subsequently a 22% increased rate of barrier restoration ($p<0.05$). Additionally, PFKFB3 inhibition led to accumulation of the recycling endosome marker Rab11a at cell junctions, which colocalized with VE-cadherin/β-catenin complexes. **Conclusions:** These findings show that spatial regulation of ATP production by PFKFB3 is necessary for the restoration of endothelial AJs following injury, indicating the importance of compartmentalized modulation of ATP levels and providing a better understanding of the metabolic regulation of AJ disassembly, trafficking and re-assembly. Modulating compartment-specific glycolysis could lead to the development of novel therapeutic approaches in which endothelial barrier function is acutely compromised.

P416/B426

Synuclein Regulates AP2-recruitment to the Membrane.

K. J. Vargas, J. R. Morgan; Marine Biological Laboratory, Woods Hole, MA.

α-Synuclein is a presynaptic protein whose mutation and aggregation is associated with several neurodegenerative disorders, including Parkinson's disease. It is highly expressed in the presynaptic compartment where it associates with synaptic vesicles. Recent studies indicate that α-synuclein regulates clathrin mediated synaptic vesicle endocytosis under physiological and pathological conditions. However, the molecular mechanism by which this occurs remains unknown. Here, we show that α-synuclein binds to isolated synaptic membranes in an ATP-dependent manner, similar to the clathrin adaptor protein AP2. In contrast, other endocytic proteins, such as clathrin heavy chain and the large GTPase dynamin-1 bind to synaptic membranes independently of ATP. This suggests that α-synuclein and AP2 share a common synaptic membrane recruitment pathway. To test this, we performed a membrane recruitment experiment using control and α-synuclein immunodepleted cytosol as a source of protein. After α-synuclein immunodepletion, the recruitment of AP2 to synaptic membranes was significantly reduced. These results suggest that α-synuclein participates in the recruitment of AP2 to the membrane, one of the key steps in the initiation of clathrin coated pits. Our next step will be to explore the localization of AP2 and α-synuclein, in subdomains of synaptic clusters in the lamprey giant axons. Finding the mechanism by which α-synuclein regulates clathrin-AP2 dependent synaptic vesicle endocytosis is important because it will allow us to understand the physiological function of α-synuclein in the synapse and how this function could be affected in pathological conditions, creating opportunities for the design of new therapeutic approaches.

P417/B427

Visualizing the Cellular Route of Entry of a Cystine-knot Peptide with Xfect.

X. Gao; GENENTECH, South San Francisco, CA.

Cyclotides or cyclic cystine-knot peptides have emerged as a promising class of pharmacological ligands that modulate protein function. Interestingly, very few cyclotides have been shown to enter into cells. Here we studied the cellular behavior of EETI-II, a model acyclic cystine-knot peptide. We uncover that EETI-II is efficiently uptaken via an active endocytic pathway to early endosomes in mammalian cells, eventually accumulating in late endosomes and lysosomes. Notably, co-incubation with a cell-penetrating peptide (Xfect) enhanced the cellular uptake and altered the trafficking of EETI-II, leading to its evasion of lysosomes. Internalized EETI-II subsequently accumulates in intracellular Xfect-induced detergent-resistant membrane compartments which appear to lack characteristic endosomal or lysosomal markers. Our results demonstrate the feasibility of modulating the subcellular distribution and intracellular targeting of cystine-knot peptides, and underscore the need for the development of effective tools to enhance the cytosolic delivery of cystine-knot peptides.

P418/B428

Potential Role for Snx17 in Coupling Receptor Cargo to Endosomal Fission Machinery.

K. Dhawan, N. Naslavsky, S. H. Caplan; University of Nebraska Medical Center, Omaha, NE.

Following endocytosis, receptors internalized to sorting endosomes (SE) are sorted to different pathways, in part by sorting nexin (SNX)proteins. Notably, SNX17 interacts with a multitude of receptors

in a sequence-specific manner to regulate their recycling. However, the mechanisms by which SNX17-labeled vesicles that contain sorted receptors bud and undergo vesicular fission from the SE remain elusive. Recent studies suggest that a dynamin-homologue, EHD1, catalyzes fission and releases endosome-derived vesicles for recycling to the plasma membrane. However, the mechanism by which EHD1 is coupled to various receptors and regulates their recycling remains unknown. Herein, we seek to characterize the mechanism by which EHD1 couples with SNX17 to regulate the recycling of SNX17-interacting receptors. *Our central hypothesis is that SNX17 couples receptors to the EHD1 fission machinery.* Co-immunoprecipitations and in vitro assays provide evidence that EHD1 and SNX17 directly interact. In addition, SNX17 and EHD1 partially co-localize on endosomes. Moreover, SNX17-containing endosomes are larger in EHD1-depleted cells compared to wild-type cells, suggesting that EHD1 depletion impairs SNX17-endosomal fission. This study helps clarify our current understanding of endocytic trafficking, by providing significant new insight into one of the least characterized trafficking steps—endosomal fission.

Stabilin-2 Is a Major Clearance Receptor for Bacterial Lipopolysaccharides in the Liver.

F. Cabral[1], L. P. Ganesan[2], M. Rajaram[2], E. N. Harris[1]; [1]University of Nebraska, Lincoln, NE, [2]The Ohio State University- Department of Internal Medicine, Columbus, OH.

Lipopolysaccharides (LPS) is a membrane lipid commonly associated with Gram negative bacteria and induces rapid inflammation by immune cells. The liver is the primary clearance organ of LPS in blood which commonly originates from the gut flora. Previous reports indicate that both Kupffer cells and hepatocytes bind and internalize LPS by scavenger receptor B1 (SR-B1) which has a slow internalization turnover rate. In contrast, blood-born LPS is cleared very rapidly by liver sinusoidal endothelial cells (LSECS) to prevent or mitigate a swift inflammatory response. Here, we provide evidence that Stabilin-2 is the primary scavenger receptor for LPS which undergoes rapid endocytosis and recycling within 11 minutes. LPS was modified with 4-hydroxyl-N-methylbenzimidine and radiolabeled with carrier-free ^{125}I using the Chloramine T method. The modification did not affect LPS-mediated activation of RAW264.7 macrophages. To assess specific endocytosis of LPS by the Stabilin receptors, one microgram/mL ^{125}I-LPS was incubated with HEK293 cells stably expressing either Stabilin-1 or Stabilin-2 receptors. Only Stabilin-2 cells showed robust internalization of ^{125}I-LPS over Stab1 cells and empty vector control cells that do not express any Stabilin receptor. Liver sinusoidal endothelial cells (LSECs) were also isolated and purified from mouse livers from the wildtype C57BL/6J strain and genetically modified strains as follows: Stabilin-1 KO, Stabilin-2 KO, and Stabilin-1/-2 double KO. Our preliminary results suggest that the single KO strains of the Stabilins decreased uptake of LPS and the double KO had a substantial decrease in LPS internalization. A decrease in LPS uptake was also correlated with increased cytokine production from bone marrow derived macrophages in the KO mouse lines. These data demonstrate that LPS is rapidly eliminated from circulation in part by the Stabilin receptors to mitigate activation by macrophages.

P420/B430

Clathrin Lattices Are a Dynamic Signaling Platform for the Egf Receptor in Human Cells.

M. A. Alfonzo Mendez, 20892, K. A. Sochacki, 20892, J. W. Taraska, 20892; National Heart, Lung, and Blood Institute, NIH, Bethesda, MD.

Clathrin-mediated endocytosis (CME) is key to internalize solutes, lipids, and integral proteins from the plasma membrane of eukaryotic cells. It is well known that classical CME occurs through the assembly of clathrin-coated pits which invaginate to form clathrin-coated vesicles. Additionally, clathrin can assemble as flat honey-comb like structures called flat clathrin lattices (FCLs) or plaques. FCL biogenesis and its potential roles in cell signaling, however, remains elusive. Here we used quantitative fluorescence and electron microscopic imaging to show that clathrin remodels in response to external signals such as the Epidermal Growth Factor (EGF). Specifically, nanoscale analysis of the plasma membrane show a dramatic increase in plaque-covered areas and plaque size with EGF stimulation. These effects required Epidermal Growth Factor Receptor (EGFR) interactions with EGF and β5-integrin phosphorylation by Src. Remarkably, agonist leads to persistent recruitment of EGFR, β5-integrin and Grb2 into clathrin structures and a corresponding loss of Src and Akt. Our results suggest that clathrin plaques remodel in response to growth factor signals and act as stable platforms capable of clustering and organizing dynamic signaling complexes at the plasma membrane.

P421/B431

Cargo-dependent Recruitment of the Endocytic Adaptor Protein Sla1.

T. Tolsma, **S. Di Pietro**; Colorado State University, Fort Collins, CO.

Selective internalization of integral membrane proteins from the cell surface is mediated by their interaction with endocytic machinery adaptor proteins. Emerging evidence suggests the converse relationship could also be true and, therefore, adaptor protein recruitment to the plasma membrane may depend on binding to endocytic cargo proteins. To test this idea we analyzed the yeast adaptor protein Sla1, which binds membrane proteins harboring the endocytic signal NPFxD via the Sla1 SHD1 domain. Consistent with the premise, point mutation of the SHD1 domain at key residues that disrupt binding to NPFxD caused a reduction of Sla1-GFP recruitment to endocytic sites. As previously reported, deletion of the Sla1 SR region that links Sla1 to Pan1 and End3 uncoupled Sla1-GFP from endocytic sites and resulted in broad recruitment of Sla1-GFP to the plasma membrane. Simultaneous deletion of the SR region and SHD1 point mutation resulted in total loss of Sla1-GFP localization to the plasma membrane indicating that interaction with cargo plays a key role in Sla1 recruitment. FRAP experiments with Sla1-ΔSR-GFP showed quick fluorescence recovery both at endocytic sites and at other locations consistent with a cargo-based recruitment to the plasma membrane. While expression of the SHD1 domain alone could not be detected at the plasma membrane, two and three SHD1 copies in tandem did result in plasma membrane localization suggesting multiple interactions are needed for stable recruitment. Interestingly, a Sla1 fragment containing just the SH3-3 and SHD1 domains also resulted in robust and broad plasma membrane localization. Given that SH3-3 binds ubiquitin, this result indicates the SH3-3-SHD1 fragment is recruited to the membrane via interaction with both NPFxD-containing and ubiquitinated plasma membrane proteins. Consistently, point mutation that impede SH3-3-SHD1 fragment binding to NPFxD or ubiquitin drastically reduced membrane recruitment. Our results also infer that the Sla1 SR region may regulate the interaction of Sla1 with NPFxD-containing cargo, potentially limiting Sla1 recruitment to the plasma membrane outside of endocytic sites. In addition

reduced cargo binding by Sla1 results in enhanced nuclear localization, giving new insight and support into the concept of endogenous nuclear Sla1.

P422/B432

AP-1B Facilitates Endocytosis during Cell Migration.

M. J. Kell, S. An g, L. Pigati, A. Halpern, **H. Fölsch**; Northwestern University, Chicago, IL.

The epithelial cell-specific clathrin adaptor complex AP-1B has a well-established role in polarized sorting of cargos from recycling endosomes to the basolateral membrane (Fölsch, 2015). Here we demonstrate a novel function for AP-1B during collective cell migration of epithelial sheets. We show that the cell-matrix adhesion molecule β1 integrin was dependent on AP-1B and its co-adaptor, autosomal recessive hypercholesterolemia protein (ARH), for sorting to the basolateral membrane. During cell migration, we found that AP-1B colocalized with β1 integrin in focal adhesions. Using stochastic optical reconstruction microscopy (STORM) and live total internal reflection fluorescence (TIRF) imaging we identified numerous AP-1B-coated structures at or close to the plasma membrane in cell protrusions. Using TIRF microscopy on fixed specimens we further found that AP-1B localized to the plasma membrane in areas that are distinct from AP-2 localization and both AP-1B and AP-2 did not show overlapping staining. Moreover, immuno-electron microscopy confirmed AP-1B labeling in clathrin-coated vesicles and pits originating at the plasma membrane in cell protrusions. Taken together, our data establish a novel role for AP-1B in endocytosis. Notably, we found that expression of AP-1B slowed epithelial-cell migration in wound healing assays using gain-of-function and loss-of-function approaches. Importantly, qRT-PCR analysis of human epithelial-derived cell lines revealed a loss of AP-1B expression in highly metastatic cancer cells indicating that AP-1B-facilitated endocytosis during cell migration might be an anti-cancer mechanism. Reference:Fölsch, H. 2015. Role of the epithelial cell-specific clathrin adaptor complex AP-1B in cell polarity. *Cell Logist*. 5:e1074331.

P423/B433

Ultrafast Endocytic Vesicle Trafficking at Synapses.

T. Ogunmowo; Johns Hopkins University Sch Med, Baltimore, MD.

Endocytosis allows a cell to remodel its membrane architecture and membrane protein composition. In most cell types, vesicles are delivered to endosomes for recycling or other processes by a stochastic interplay between active transport (molecular motor-mediated) and passive diffusion. However, trafficking mechanisms at neuronal synapses must be rapid and precise because synaptic vesicles, used for neurotransmission, must be recycled in seconds. Traditionally, synaptic vesicle recycling was thought to involve endocytosis alone, but recent work suggests a two-step system, whereby endocytic vesicles are trafficked to a synaptic endosome for synaptic vesicle regeneration. Strikingly, both endocytosis and endosomal trafficking occur within 1 s following fusion —the kinetics and precision of which cannot be explained by classic transport mechanisms (1-2 minutes). Thus, it is unclear how this ultrafast trafficking occurs at synapses. My preliminary data suggest that actin polymerization and Intersectin-1, a multimodal endocytic adaptor protein implicated in various synaptic functions, are required for the kinetics of post-endocytic trafficking of endocytic vesicles. However, how Itsn1 activity is regulated, what actin-related factors Itsn1 works with, and how nascent actin polymers function during post-endocytic trafficking remains unclear.

P424/B434

Regulation of Actin Polymerization during Clathrin-mediated Endocytosis by the Tda2-Aim21 Complex.

A. Lamb, S. Di Pietro; Colorado State University, Fort Collins, CO.

Clathrin-mediated endocytosis (CME) is a major endocytic pathway that is essential in all eukaryotic cells. The highly conserved process involves the sequential assembly of nearly 60 proteins at endocytic patches along the plasma membrane. These endocytic factors work together to collect cargo into a clathrin-coated pit, invaginate the surrounding membrane, and pinch off the invagination as a vesicle inside the cell. In budding yeast CME, polymerization of actin into a branched network is critical to provide the force necessary for membrane invagination. Recently, our lab identified Tda2 as a novel component of the CME machinery. Unexpectedly, the crystal structure of Tda2 revealed it to be a homodimer and structural homolog to the TcTex1 type dynein light chain, the first of its kind in yeast. Additionally, Tda2 was found to form a stable complex with the little-studied endocytic factor Aim21. Despite these findings, the function of Tda2 in CME has remained largely elusive. Here, we utilized numerous biochemistry and cell biology-based techniques to further elucidate the molecular function of Tda2 during CME in budding yeast. The interaction of Tda2 to Aim21 was mapped to a 16-amino acid sequence of Aim21 near its C-terminus. Two amino acids of Aim21, F533 and W536, were found to be particularly important for the interaction with Tda2. Fluorescence microscopy showed that these hydrophobic amino acids are critical for the localization and function of Tda2. Biochemical techniques demonstrated that the Tda2 homodimer functioned to bring together two copies of Aim21, acting as a dimerization chaperone. In turn, dimerization of Aim21 near its C-terminus proved necessary for its interaction with Actin Capping Protein (Cap1/2), an endocytic factor that binds the barbed-end of actin filaments, preventing addition or loss of actin subunits. Disruption of the Tda2-Aim21 interaction resulted in decreased levels of Cap1/2 at endocytic patches and a prolonged phase of actin polymerization. Thus, this work has shown Tda2 to function as a dimerization chaperone for Aim21 during CME, supporting what others have postulated as the function of dynein light chains in the dynein motor complex. Moreover, the Tda2-Aim21 complex through its interaction with Cap1/2 appears to be an important player in regulating the branched actin network during yeast CME.

α-Arrestin Regulation of Protein Trafficking: Using Evolutionary Rate Covariation to Define Protein Trafficking Regulatory Networks.

K. P. Callahan[1], T. Finkelstein[1], A. Malik[1], D. A. Augustine[1], A. Nikiforov[2], H. Serbin[1], Z. Ferreria[1], N. Clark[1], A. F. O'Donnell[1]; [1]University of Pittsburgh, Pittsburgh, PA, [2]Duquesne University, Pittsburgh, PA.

Alpha-arrestins help cells survive environmental changes by controlling membrane protein trafficking. One hurdle to understanding α-arrestins is that few α-arrestin-cargo pairs have been identified. It is technically challenging to identify membrane cargos due to their transient associations with α-arrestins and their biochemical nature. to identify α-arrestin-regulated cargos, we used Evolutionary Rate Covariation (ERC), which employs sequence-based signatures to identify genes with similar evolutionary histories. We compared ERC values for α-arrestins with cargos across 18 yeast species. Among the top co-evolving proteins were those previously defined as α-arrestin cargos. We are determining if the membrane proteins with the highest ERC values (>0.5) are α-arrestin cargos by assessing their localization and relative protein abundances in wild-type cells versus those lacking the specific α-arrestins. Fluorescence intensity was used to quantify the abundance and/or subcellular distribution of

GFP tagged proteins. Statistically significant changes in GFP abundance or localization between wild-type cells and those lacking α-arrestins demonstrate dependence on these protein trafficking adaptors. This makes them good candidates as new α-arrestin-dependent cargos, which we are confirming by co-localization, bimolecular fluorescence complementation and biochemical approaches. Using ERC and our fluorescence imaging pipeline, we have quantitatively confirmed that 36 integral membrane proteins previously unassociated with α-arrestins display α-arrestin-dependent localization changes. This greatly expands the repertoire of α-arrestin cargo within cells, and raises important functional implications for this family. In conclusion, the ERC approach is a powerful new tool that is able to define protein trafficking regulatory networks, which will undoubtedly be of interest to the cell biology community.

P426/B436

Studying Dynamics and Mechanics of Clathrin-mediated Endocytosis in the Native Tissue Context.

M. Mund, A. Picco, M. Kaksonen; University of Geneva, Geneva, SWITZERLAND.

Clathrin-mediated endocytosis (CME), an essential cellular function in eukaryotes, has been extensively studied using adherent cultured cells. These cells, however, are artificially flat and lack the physiological tissue environment, which influences the mechanical properties of the plasma membrane. Thus, the question how CME is adapted to the functional and architectural diversity of cells and tissues, remains poorly understood. Here, we aim to understand how CME functions in the native tissue context. Generally, we ask whether CME is performed by an adapted machinery and occurs with specific spatiotemporal dynamics in different cells and tissues. We used *Drosophila melanogaster,* which combines the advantages of a versatile genetic toolkit, a comparably small genome and accessibility to a variety of imaging modalities. Using CRISPR we created fly lines where endocytic proteins are endogenously tagged with fluorescent markers. We then used fluorescence microscopy and particle tracking to follow individual endocytic events and measure their dynamics with high spatiotemporal resolution.In our experiments, we imaged intact *Drosophila* pupae, which are non-motile. We focused on the single-layered epithelium at the notum, which is at the very surface and thus well-suited for microscopy. Within this epithelium, individual precursor cells undergo stereotypic divisions to form mechanosensory organs, each consisting of a bristle, socket, neuron and sheath cell. We use this organ as model system to image CME within tissue, throughout cell division and differentiation. This approach allowed us to record individual endocytic events in living fly pupae with a similarly high resolution as in cell culture, allowing us to precisely determine their lifetimes and dynamic trajectories. We find that endocytic events are temporally highly regular, and observed intriguing changes in the dynamics of endocytic events in bristle cells. We hypothesize that in these cells, CME is reprogrammed during development, potentially in response to changing cellular function and architecture. To investigate this question in more detail, we will study how actin and actin-binding proteins contribute to force generation during CME, how changes in membrane tension affect endocytic dynamics, and how CME adapts during differentiation also in the neuron and the socket cell of the mechanosensory organ.

Protein Droplets Catalyze Assembly of Endocytic Vesicles.

K. J. Day[1], G. K. Kago[1], J. B. Richter[2], C. C. Hayden[1], E. M. Lafer[2], J. C. Stachowiak[1]; [1]Biomedical Engineering, University of Texas at Austin, Austin, TX, [2]Biochemistry, University of Texas Health Science Center at San an tonio, San an tonio, TX.

During clathrin-mediated endocytosis, dozens of adaptor and coat proteins assemble into a mesh-like network at the plasma membrane, where they work together to drive vesicle formation. Fcho1 and Eps15 are among the earliest adaptors to arrive at endocytic sites. These initiator proteins are responsible for recruiting, concentrating and organizing downstream components at the membrane surface. However, as the budding vesicle grows, the initiator proteins must also allow dynamic rearrangement of the adaptor network. It is unclear how initiator proteins are able to meet these competing demands. Toward explaining this apparent paradox, we have made the exciting discovery that Fcho1 and Eps15 assemble into liquid protein droplets at membrane surfaces. Droplet assembly requires specific protein domains in Fcho1 and Eps15 that contribute to the ability of the two proteins to form a multivalent network. Further, these droplets exhibited liquid-like properties, including coalescence and dynamic exchange of proteins in and out of droplets. Toward characterizing the phase behavior of these initiators over a range of biochemical conditions, we have modulated protein concentrations, temperature, and crowding conditions to develop a set of phase diagrams. The liquid properties of Fcho1/Eps15 protein droplets can explain how the downstream adaptor network is tightly concentrated yet also dynamic. To test the role of Fcho1/Eps15 liquid assemblies in live mammalian cells, we developed an assay that allows us to tune the strength of initiator protein assembly in real time using light. Specifically, we created a chimeric version of Eps15 that contains a light-inducible oligomerizing domain, Cry2. Application of low light levels drove fluid assembly of the initiator proteins. These fluid assemblies resulted in an increase in endocytic initiation events. In contrast, high light levels drove the formation of solid initiator complexes, which stalled vesicle dynamics. These results indicate that solid assemblies of initiator proteins are unable to release endocytic assemblies. In contrast, more fluid assemblies can serve as strong yet dynamic catalysts. These results suggest that the liquid-like behavior of Fcho1/Eps15 droplets is important for effective catalysis of clathrin-mediated endocytosis in cells.

CMEpi, a Potent and Selective Structure-based Inhibitor of Clathrin-mediated Endocytosis.

Z. Chen, R. Mino, M. Mettlen, P. Michaely, M. Bhave, D. K. Reed, S. L. Schmid; UTSouthwestern Medical Center, Dallas, TX.

Clathrin-mediated endocytosis (CME) is a predominant route of entry into cells via the formation of clathrin-coated vesicles. The major coat proteins are clathrin and AP2. Tools to address CME function, especially a specific inhibitor that works by rapid and well-defined mechanism, are in great demand. Here we revealed that overexpression of N-terminal fragments of the clathrin heavy chain encoding the terminal domain (TD) with or without the distal leg potently and specifically inhibit CME and CCP dynamics, primarily through the interference of AP2 and SNX9 functions. Furthermore, we designed small membrane-penetrating peptide mimics of the binding surfaces on the TD and observed differential inhibitory abilities. A peptide corresponding to the W-box motif binding site was identified as the strongest CME inhibitor, also by the mechanism of inhibiting AP2 and SNX9 functions. This peptide

inhibitor, which we named CMEpi, does not affect other endocytic pathways and even other clathrin-dependent trafficking event, such as AP1-dependent Golgi trafficking.

Regulation of the Yeast Transporter-like Glucose Receptor-mediated Signaling Pathway.

C. K. Lillestolen, R. N. Rodriguez, K. N. Price, B. L. Kenny, J. Kim; Liberty University, Lynchburg, VA.

Defects in glucose sensing are at the root of a number of metabolic disorders. Impaired regulation of blood glucose levels may cause severe metabolic disorders, such as diabetes, and many types of cancer cells depend on a high rate of glucose consumption to maintain their viability. Thus, learning how cells sense and respond to glucose is of great interest and major significance. The yeast *Saccharomyces cerevisiae* senses glucose through two transporter-like glucose receptors (TLGRs) Rgt2 and Snf3, formerly known as glucose sensors. Evidence indicates that TLGRs act as glucose receptors that generate an intracellular signal in response to glucose that induces expression of genes involved in glucose uptake and metabolism. However, the underlying mechanisms are largely unknown. The objective of this study is to test the hypothesis that TLGR signaling activity may be regulated by extracellular glucose concentrations. To achieve this objective, we assessed the cell surface expression of TLGRs using biochemical and cell biological approaches. Several lines of evidence show that TLGRs are endocytosed and degraded in the vacuole in glucose-starved yeast cells and that TLGR turnover is mediated by ubiquitination. TLGRs are mainly localized to the plasma membrane when glucose is present but targeted to the vacuole for degradation when glucose is depleted from the medium. However, TLGR turnover is impaired in cells lacking the End3 protein involved in endocytosis, the Doa4 deubiquitinase and the Rsp5 ligase. It has been postulated that Rgt2 and Snf3 have respectively low and high affinities for glucose. Our results show that Rgt2 is endocytosed and degraded in low glucose-grown cells, whereas Snf3 is downregulated in cells grown in high glucose. Thus, Rg2 is expressed at the cell surface in low conditions, while Snf3 is expressed in high glucose conditions. Consistently, constitutively active TLGRs $Rgt2^{R231K}$ and $Snf3^{R229K}$ are shown not to undergo endocytosis, suggesting that both are endocytosis resistant TLGRs. Taken together, our results suggest that cell surface expression levels of TLGRs are tightly associated with their ability to sense glucose. In conclusion, it has long been hypothesized that TLGRs are expressed constitutively and undergo a conformational change upon glucose binding, leading to activation of the receptors. By contrast, our results show that TLGRs are constantly targeted to the vacuole for degradation and expressed at the cell surface only when the extracellular concentration of glucose is in the range of their respective affinities and suggest a novel mechanism for this glucose sensing and signaling system.

Rock2 Mediated Myosin Contractility Is Required for Internalization of CIE Cargo Proteins.

J. Wayt, 2089; National Institutes of Health, Bethesda, MD.

Endocytosis is an important event that cells utilize to internalize cell surface proteins and fluid into the cell. There are two main forms of endocytosis: clathrin-mediated endocytosis (CME) and clathrin-independent endocytosis (CIE), amongst which CME is the most studied. While CME is important for the internalization of specific surface proteins, bulk trafficking of fluid and membrane occurs primarily in a clathrin-independent manner. While we have established the trafficking itinerary of many classical CIE cargoe proteins, such as CD59 and Major Histocompatibility Complex Class I (MHCI), little is known

about the cellular machinery involved in CIE. To identify proteins essential for the internalization of the GPI-anchor protein CD59 and the cell surface protein MHCI in Hela cells, we designed an siRNA screen utilizing the Dharmacon™ Membrane Trafficking library, which contains siRNA targeting 140 established membrane trafficking genes. Among these candidates was the kinase ROCK2, which upon depletion inhibited internalization of both cargo proteins, a result which was further confirmed using small molecule inhibitors of ROCK2. This phenotype was specific to ROCK2, as knockdown of the homologous protein ROCK1 had no effect on the internalization of either cargo. ROCK2 regulates the phosphorylation and subsequent deactivation of the actin severing protein Cofilin. Knockdown of Cofilin stimulated the internalization of both MHCI and CD59 and resulted in the accumulation of cargo in enlarged vesicles located in a dense actin network at the cell periphery. ROCK2 also positively regulates myosin contractility through the phosphorylation and subsequent activation of myosin light chain (MLC). Inactivation of Myosin II using blebbistatin results in decreased internalization of both cargo, to a similar extent as ROCK2 knockdown. This would suggest that ROCK2 regulation of both MLC and Cofilin is important for CIE cargo internalization. To further characterize Myosin II in CIE, two isoforms of Myosin II (Myo2A and Myo2B) were inhibited and CIE was monitored. Interestingly, internalization of MHCI required Myo2A, while CD59 required Myo2B. There is evidence to suggest that in polarized cells distinct functions of Myo2A and Myo2B are more evident. In polarized Caco-2 cells, we observe that CD59 localizes and internalizes via the apical domain and MHCI internalizes via the basolateral domain. Silencing of Myo2A in polarized Caco-2 cells inhibits MHCI internalization, while inhibition of Myo2B has no effect. This would suggest that CIE in polarized cells also exhibits preferential myosin isoform requirements, and makes polarized cells an intriguing system for gaining insight into differential Myosin II isoform requirements for internalization of CIE cargo proteins.

P431/B441

CLIC Cargo Uptake Is Largely Dependent Upon Microtubule Integrity and Microtubule-Associated Motor Functions.

T. Wang, A. Tiwari, A. K. Kenworthy; University of Virginia, Charlottesville, VA.

Cellular internalization pathways can be categorized, based on their requirement for clathrin components, into clathrin-mediated endocytosis (CME) and clathrin-independent endocytosis (CIE). One major pathway of the CIE group is the clathrin-independent carrier (CLIC) or glycosylphosphotidylinositol-anchored protein enriched compartments (GEECs) mediated endocytosis. CLIC/GEEC is responsible for the internalization of many physiologically important cell surface factors and channels including CD44, CD59, CD147, and MHCI. Yet the mechanisms of CLIC cargo uptake is not very well understood. In recent years, accumulated evidence from our lab and other groups suggests the microtubule network and dynein motors are closely linked to this process, perhaps by facilitating membrane fission and the generation of CLIC/GEEC carriers. Utilizing cell surface receptors CD44 and CD59, we seek to further elucidate the relationship between CLIC uptake, the microtubule network, and dynein motors. We demonstrate that compared to the uptake of transferrin by CME, CD44 and CD59 not only internalize through distinct compartments and components, but CLIC uptake is far more sensitive to microtubule disruption by the drug Nocodazole, suggesting a higher dependency on the integrity of microtubule network. Furthermore, we show that in comparison to CME, the CLIC/GEEC pathway displays higher sensitivity to dynein motor inhibitor Ciliobrevin D, as well as to the overexpression of p50/dynamitin, which acts as a dominant negative construct for the dynein complex. However, we observe the effects of dynein motor inhibition on CLIC uptake is less dramatic than that of

the microtubule disruption, possibly hinting at the involvement of other motors and/or alternative mechanisms. Our data contribute to a growing body of evidence suggesting a complex network of microtubule and motor components collaborating to bring in CLIC cargos, in a mechanism remarkably different from the well-established CME pathway.

P432/B442
Phase Separation in the Early Endocytic Protein Network.
M. Kozak, M. Kaksonen; University of Geneva, Geneva, SWITZERLAND.

Clathrin-mediated endocytosis is a major pathway used by eukaryotic cells to produce transport vesicles from the plasma membrane. In yeast, the assembly of endocytic machinery is an ordered process that involves dozens of different proteins such as clathrin adaptors, coat proteins and actin cytoskeletal proteins. The initiation step of endocytosis is highly redundant, but the exact mechanism that underlies this flexibility is unknown. The early coat is a dynamic network of weak protein-protein interactions. Many early proteins have high turnover rates, and yet their function is to recruit and concentrate cargo and downstream effectors. Ede1, the yeast homologue of mammalian Eps15, is one of the earliest-arriving endocytic proteins. In EDE1 deletion strains, many early proteins become diffuse on the membrane instead of assembling into discrete endocytic sites. This indicates that Ede1 is a key factor in early site formation. However, Ede1 lacks membrane-binding domains and relies on ubiquitinylated cargo and endocytic adaptors for recruitment to the PM. In strains deficient in such adaptors, the Ede1 protein forms bright and long-lived clusters. We show that this phenotype is concentration-dependent and can be mimicked by over-expressing Ede1. We also demonstrate that that these clusters exhibit dynamic properties of liquid droplets and that temperature can modulate their phase behaviour. The droplets also recruit many other endocytic proteins, and can initiate bursts of actin polymerization. In many respects, the droplets resemble genuine endocytic sites. We used the droplet formation as a tool to study the properties of Ede1 and discovered that the phase separation depends on a core region containing a low-complexity sequence and a coiled-coil domain. When we deleted this core region, Ede1 and other early proteins no longer localized to distinct endocytic sites, and initiation was impaired. On the other hand, fusion with the Ede1 core region induced a punctate localization of an otherwise diffuse heterologous membrane associated protein. These results allow us to explain the importance of self-associating Ede1 regions in endocytic initiation. We also propose that the concentration of cargo and adaptors during the early phase of endocytosis might be a phase separation process facilitated primarily by Ede1.

Rab GTPases

Arf-like Gtpase 15 Modulates the Biogenesis of Filopodia.
P. Sharma, S. R. Gangi Setty; IISc, Bangalore, INDIA.

Arf and Arf-like (Arl) GTPases regulate several cellular processes such as intracellular transport, cytoskeletal organization etc. The functions of few Arls have been well studied, but the role of Arl15 in any of these processes remains elusive. Studies have reported that Arl15 may influence the adiponectin levels and is also implicated in metabolic disorders like type 2 diabetes, coronary heart disease, rheumatoid arthritis and childhood obesity. Further, Arl15 is shown to associate with golgi upon insulin

stimulation. In this study, we aim to understand the molecular function of Arl15 in vesicular transport and other cellular processes by using cellular model system. Expression of Arl15 as a GFP/mCherry fusion in several cell types revealed its localization to cell surface, protrusions and tunnel-like nanotubes (TNTs). Consistently, Arl15 in HeLa cells colocalize with PLCdelta-PH (PIP2 binding protein), Fascin (filopodia-specific protein), phalloidin (labels F-actin) and M-Sec (TNT marker). Intracellularly, Arl15 localizes to golgi and a cohort to endocytic-recycling compartments (ERCs). As expected, Arl15 showed colocalization with Rab11/22A (ERC markers) and GM130/Golgin 245 (golgi-tethering proteins). To understand the dynamic association of Arl15 with multiple membranes, several point mutations were carried out as identified in homology analysis with other Arl family members. These mutations include $Arl15^{S2G}$ (myristoylation-positive mutant), $Arl15^{S2A}$ (phospho-dead mutant), $Arl15^{S2E}$ (phospho-mimetic mutant), $Arl15^{T46N}$ (dominant negative mutant), $Arl15^{A86L/A86Q}$ (constitutive active mutant) and $Arl15^{S2G, A86L}$/$Arl15^{S2G, T46N}$ (double mutants). Interestingly, $Arl15^{A86L}$ and $Arl15^{S2G, A86L}$ localize to the cytosol and disengage from the cell surface/filopodia, suggesting $Arl15^{A86L}$ possibly acts as a dominant negative mutant. Next, we tested the role of cortical actin in recruiting Arl15 to the filopodia. Latrunculin a treatment did not alter the cell surface/golgi localization of Arl15. However, golgi fragmentation by using brefeldin-A (targets GBF1, Arf1 GEF) completely abolished the Arl15 localization, similar to Arf1 and other golgi proteins like Grasp-55. These results indicate the Arf1-dependency for Arl15 recruitment to the membranes. In line, over expression of dominant negative mutant of Arf1, $Arf1^{T31N}$ mislocalizes Arl15 to cytosol, suggesting Arf1 GTPase cycle is crucial for the Arl15 localization. Preliminary analysis of Arl15-knockdown in HeLa cells showed defective cell migration and transferrin recycling without affecting the golgi integrity. Overall, this study indicates that Arf1 dependent recruitment of Arl15 possibly regulates the vesicular transport from golgi towards the cell surface for filopodia biogenesis.

P434/B444

Tumor Suppressor Activity of Rab17 Is GTP-dependent.

L. R. Bassaro, M. R. Shaffern, P. L. Tuma; the Catholic University of America, Washington, DC.

We recently found that rab17 regulates the last step of hepatic basolateral-to-apical transcytosis via selective interactions with syntaxin-2 at the apical surface. We further determined that optimal apical vesicle docking/fusion requires rab17 mono-sumoylation and GTP hydrolysis. Studies by others have implicated rab17 as a tumor suppressor in hepatocellular carcinoma (HCC) based on the finding that patient malignant lesions expressed significantly lower levels of rab17 compared with adjacent paraneoplastic tissue. Furthermore, rab17 overexpression in HCC cell lines ameliorated the tumorigenic phenotype while its knockdown enhanced invasiveness. We are examining the mechanisms by which rab17 antagonizes the oncogenic phenotype. Because rab17 overexpression promotes dendrite formation in neuronal cells, we have been monitoring actin-based surface structures in hepatoma cells exogenously expressing wild-type rab17, sumoylation-deficient (K68R), or constitutively GTP- (Q77L) or GDP-bound (N132I) rab17. Consistent with studies in neuronal cells, expression of wild-type rab17 cells led to the formation of filipodia-like protrusions and cell ruffles with rab17 colocalized with syntaxin-2 at the distal tips and in ruffles. Interestingly, expression of either the GTP-bound or sumo-deficient rab17 promoted modest membrane ruffling, blunted protrusion formation and maintained colocalization with syntaxin-2. However, expression of wild type, GTP-bound and sumo-deficient rab17 did not change the surface distributions of Mena, VASP or WDR1. In contrast, GDP-bound rab17 did not distribute to the cell surface nor did it promote changes in cell morphology, but it did lead to loss of VASP cell surface distributions. Despite the formation of actin-based protrusions, cells expressing either wild-type or GTP-

bound rab17 showed impaired migration when monitored by live cell imaging in scratch assays whereas cells expressing GDP-bound rab17 displayed no changes in migration. These results suggest that rab17 expression promotes GTP-dependent protrusion formation which correlates with impaired motility. Based on rab17 colocalization with syntaxin-2, we propose that rab17 antagonizes the oncogenic phenotype by redirecting vesicular cargo to distinct surface domains thereby preventing cellular reorganization required for collective cell migration and invasion.

P435/B445

An Enlarged Rab4-modulated Endosomal Compartment Is the Site of Prolonged Egfr Activation in Breast Cancer Cells.

K. Tubbesing, R. Abini-Agbomson, J. Ward, A. Alena Rudkouskaya, M. M. Barroso; Albany Med Coll, Albany, NY.

Early sorting endosomes are responsible for the proper trafficking and function of membrane-bound receptors, required for iron uptake or signaling regulation, such as transferrin receptor (TfR) and epidermal growth factor receptor (EGFR), respectively. However, the morphology, receptor composition, and signaling of early endosomes remain poorly understood in breast cancer. We have identified a novel population of enlarged early endosomes in breast cancer cells and human tumor xenografts (human breast cancer MDAMB231 and T47D cells) but not in noncancerous epithelial cells (MCF10A). Quantitative analysis of endosomal morphology, cargo sorting, EGFR activation and Rab-GTPase regulation were performed using super-resolution and confocal microscopy followed by 3D rendering image analysis using Imaris software. Results show that aggressive triple-negative MDAMB231 cells have significantly fewer, but much larger EEA1-positive early endosomes compared to MCF10A cells. These large endosomes contain adjacent Rab4 and Rab11 domains and undergo cargo recycling via budding from actin microdomains. Live-cell imaging indicated that endocytic cargo, e.g. EGF and Tf, traffic together via these enlarged endosomes in MDAMB231 cells, but not in MCF10A. Most importantly, these large EEA1-positive MDAMB231 endosomes exhibited prolonged and increased EGF-induced activation of EGFR (p1068) using cell imaging and morphometric analysis. Importantly, knockdown of Rab4 in MDAMB231 cells lead to increased EGF-induced activation of EGFR (p1068), without significant effect on MDAMB231's already large endosomal size. In contrast, Rab4 knockdown increased endosome size but did not affect EGFR signaling activation in MCF10A cells. These results suggest that Rab4 affects endosome size and EGFR signaling differently in breast cancer vs. non-cancerous epithelial cells. Moreover, these results make evident the importance of determining the role of endosomal morphology in the regulation of EGFR signaling in breast cancer cells. In summary, an extensive characterization of early-endosomes in breast cancer cells has identified a Rab4-modulated enlarged endosomal compartment as the site of prolonged and increased EGFR activation. These findings establish the early endosomes as central players in the regulation of cargo trafficking and cell signaling in breast cancer cells.

P436/B446

ALS2 Controls the Intracellular Localization of Small GTPase Rab17 and Regulates Endosome Maturation.

S. ONO[1], K. SATO[1], S. MITSUI[1], A. OTOMO[1], M. FUKUDA[2], S. HADANO[1]; [1]Tokai University School of Medicine, Isehara, Kanagawa, JAPAN, [2]Tohoku University Graduate School of Life Sciences, Sendai, Miyagi, JAPAN.

ALS2, an autosomal recessive form of childhood-onset amyotrophic lateral sclerosis (ALS), is caused by loss-of-function mutations in the *ALS2* gene. The ALS2 protein (ALS2), the product of this gene, acts as a guanine nucleotide exchange factor (GEF) for small GTPase Rab5 and regulates the fusion and maturation of early endosomes in cells. Since ALS2 is relocalized from the cytosol to endosome by macropinocytosis via Rac1-induced membrane ruffles, it has been surmised that loss of ALS2 function results in dysfunctional intracellular membrane trafficking. However, the molecular mechanisms underlying the pathogenesis of ALS2-linked recessive motor neuron diseases are still unclear. In this study, to gain further insight into the ALS2-associated cellular functions, we focused on a novel ALS2-interacting small GTPase Rab17 and investigated the functional relationship between ALS2 and Rab17. First, we examined whether ALS2 could bind to Rab17 and act as a GEF for Rab17. GST pull-down assay revealed that ALS2 preferentially bound to $Rab17^{WT}$ (WT: wild type) and $Rab17^{CN}$ (CN: constitutively negative). However, no observable ALS2-mediated GEF activity on Rab17 was detected by the GDP-dissociation assay. The results suggest that ALS2 does not function as a GEF, but rather acts as a modulator for Rab17. Next, to clarify the Rab17-linked ALS2 cellular function, we observed the intracellular localization of ALS2 and Rab17 in HeLa cells. While Rab17 was mainly localized to Rab11-positive recycling endosomes, it was also colocalized with ALS2 in early endosomal compartments under normal cultured conditions. Further, upon Rac1 activation, Rab17 was relocalized to Rac1-induced membrane ruffles followed by internalization to early endosomes like was ALS2. Remarkably, although Rab17 recruitment to endosomes was not affected by siRNA-mediated *ALS2*-knockdown (KD), loss of ALS2 resulted in enlargement of Rab17-residing endosomes, onto which Rac1, VPS35 and LAMP-1/2 but not EEA1 were colocalized. On the other hand, pulse-chase assay using Alexa594-Tfn or Alexa488-EGF revealed that, under ALS2-deficient conditions, neither Tfn nor EGF was localized to enlarged Rab17-residing endosomes, suggesting that clathrin-mediated endocytosis (CME) was unlikely to account for Rab17 internalization to endosomes. These results suggest that ALS2 regulates the trafficking of Rab17-residing endosomes, which are formed by Rac1 activation, in a CME-independent manner. In conclusion, ALS2 might play a key role in endosome maturation not only by the activation of Rab5 but also by the regulation of Rab17 molecular function, possibly through their interaction, in cells. We are currently investigating the molecular mechanism by which Rab17-residing endosomes can be enlarged in the absence of ALS2.

P437/B447

Tnf Alpha Induced Migration and Integrin Beta 3 Levels Are Regulated by the Rab Endocytic Pathway in Reactive Astrocytes.

J. Díaz[1,2], A. Chamorro[1,2], R. Artigas[3,2], A. Corvalán[3,2], A. Quest[1,2], L. Leyton[1,2]; [1]Universidad de Chile, Santiago, CHILE, [2]Advanced Center for Chronic Diseases (ACCDiS), Santiago, CHILE, [3]Pontificia Universidad Católica de Chile, Santiago, CHILE.

Introduction: Upon injury to the central nervous system, astrocytes generate a pro-inflammatory environment required for neuronal regeneration, and undergo a process called "Gliosis" characterized by hypertrophy, astrocyte migration and increased expression of proteins including glial fibrillar acidic protein (GFAP), syndecan-4 (SDC4), and $\beta_3$integrin. Our previous data indicate that the neuronal protein Thy-1 binds to $\beta_3$integrin to promote cell migration only when astrocytes are reactive. However, the mechanisms implicated in the up regulation of $\beta_3$integrin in astrocytes under pro-inflammatory conditions remain unclear. **Material and Methods:** We performed an in *silico* comparative meta-analysis of gene expression profiles obtained from publicly available microarray datasets of non-reactive vs. reactive astrocytes.Hierarchical clustering comparisons were performed using the MultiExperiment Viewer software and affected signaling pathways were examined with Kyoto Encyclopedia of Genes and Genomes Database. DITNC1 astrocytes were treated with TNF-α for 48hrs to induce reactivity in *vitro and* $\beta_3$integrin levels were measured by Western blot and flow cytometry. GTPase activities were measured using pull-down assays. Astrocyte migration was induced using Thy-1 as a stimulus and evaluated in transwell assays. Results were compared with unpaired t tests of at least three independent experiments with a p value ≤0.05 for significance. **Results: in** the in *silico* comparative meta-analysis we found that Rab endocytic pathways were altered in reactive astrocytes. TNFα treatment changed protein expression associated with the appearance of reactivity markers, such as GFAP, and increased surface levels of $\beta_3$integrin in the DITNC1 cells. This same treatment altered Rabs and Rac1 GTP loading. Thy-1-induced astrocyte migration was also associated with the changes observed in Rab protein levels. **Conclusions:** These studies aid in understanding the molecular mechanisms involving Rab-dependent pathways in astrocyte activation, an important process observed in pathological conditions, such as neurodegenerative diseases e.g.Amyotrophic Lateral Sclerosis and brain injury.

P438/B448

The Amphipathic Motifs of Some Arf Proteins Are Required and Sufficient for Determining Specific Interacellular Localizations.

F. YANG, Clear Wate, Y. GUO; Hong Kong University Sci & Technol, Hong Kong, HONG KONG.

The localizations of Arf family proteins are generally thought to be determined by their corresponding guanine nucleotide exchange factors (GEFs). However, although the GEFs directly interact with the switch domains of Arf proteins, the amphipathic motifs at the N-terminus of Arf proteins are also important for their membrane associations. Here, we analyzed the functional roles of the amphipathic motifs of the Golgi-localized Arf family protein, Arfrp1, the endoplasmic reticulum-localized Arf family protein, Sar1A, and the endosome- and plasma membrane-localized Arf family protein, Arl14. Switching the amphipathic helix motifs among these Arf proteins causes changes of their intracellular localizations. Moreover, we found that the amphipathic helices of Arfrp1, Arl14 and Sar1A are sufficient to bring cytosolic proteins to the Golgi, the endosomes or the ER respectively. The spatial determination

mediated by Arfrp1 helix requires its binding partner Sys1. In addition, the acetylation modification on Arfrp1 helix and the myristoylation modification on Arl14 helix are important for the spatial determination. Interestingly, Sar1A, Arfrp1 and Arl14 are recruited to their specific intracellular compartments independent of GTP binding, suggesting their GTP binding and membrane association are uncoupled. In sum, our results demonstrate that the amphipathic motifs of Arfrp1, Arl14 and Sar1A are required and sufficient for determining specific intracellular localizations. In addition, our study provides novel short motifs that can be used to target cytosolic proteins to specific intracellular compartments.

Regulation of Cell Migration and GTPase Function through Mechanical Control of RNA Localization.

K. Moissoglu, M. Stueland, S. Mili; National Cancer Institute, National Institutes of Health, Bethesda, MD.

Local RNA translation is emerging as a mechanism required to stabilize protrusions and promote persistence and directionality during cell movement. Our work has shown that numerous RNAs are enriched in protrusive regions, and that localization of a subset of them is promoted by increased stiffness of the extracellular matrix. The localization of this group of RNAs is important for efficient cell migration. We have now developed a method to disrupt the localization of specific individual RNAs from this group, including that encoding Rab13, a GTPase involved in vesicle trafficking. Strikingly, preventing the localization of the Rab13 RNA at protrusions is sufficient to disrupt the ability of cancer cells to migrate on 2D surfaces or to invade through Matrigel. Through biochemical and live cell imaging approaches we find that the Rab13 RNA is similarly translated in both the cell body as well as in peripheral protrusions. Interestingly, preventing the targeting of endogenous Rab13 RNA at protrusions leads to the production of less active Rab13 protein. Similar conclusions are reached when exogenous Rab13 is expressed from a mislocalized transcript. These results reveal a novel mechanism controlling Rab13 GTPase function. Specifically, they suggest that translation of GTPases in particular local environments is important for their proper activation and function during cell movement. We are further testing this hypothesis and investigating in detail the underlying mechanisms.

Rab39 and Klp98a Are Required for Furrow Formation during Early *Drosophila* Embryogenesis.

M. Millage, H. Miao, J. T. Blankenship; University of Denver, Denver, CO.

The formation of a plasma membrane furrow is an essential process during development. Furrow formation is necessary for successful cell division and cytokinesis in addition to the ability to create multicellular tissues. Here we explore the role of the Golgi-associated Rab protein Rab39 in furrow formation during early *Drosophila* embryogenesis. Rab39 is one of eight Rab proteins that has been shown to localize to discrete puncta by live imaging in a screen in early *Drosophila* embryos, but its function and pathway have not been well characterized. We demonstrate that Rab39 forms dynamic, tubular structures that colocalize with trans-Golgi markers and that the knockdown of Rab39 using RNA interference causes defects in furrow length and nuclear division during syncytial cycles 10-13. Klp98A, a kinesin 3 family motor protein, produces similar abnormalities when disrupted and colocalizes with Rab39. In the absence of Rab39, Klp98A forms large complexes and accumulates at the Golgi. Additionally, Rab39 and Klp98A dynamics are dependent on microtubule, but not filamentous actin, networks. The Golgi associated tether Golgin245 also shows a strong furrow phenotype in disrupted

embryos and is another potential effector of Rab39. Together, these proteins could represent a novel pathway that mediate membrane trafficking from the Golgi to the plasma membrane to aid in furrow formation.

Role of Rab4 Isoforms in the Regulation of Endocytic Trafficking in Breast Cancer Cells.

R. Abini-Agbomson, K. Tubbesing, M. M. Barroso; Albany Med Coll, Albany, NY.

Cell surface receptors such as the epidermal growth factor receptor (EGFR) and Transferrin Receptor (TfR) are transported from the plasma membrane to the early endosome utilizing clathrin-mediated endocytosis. Rabs are a family of GTPases that control membrane identity, vesicle motility, and proper vesicular trafficking. Rab4, found on early endosomes, ensures that EGFR and TfR are properly sorted and recycled to the cell surface or the lysosome for degradation. However, in cancer cells, the endocytic pathway is highly dysregulated. Our previous work using confocal microscopy followed by 3D rendering software IMARIS demonstrated that endosomes derived from an aggressive triple-negative breast cancer cell line (MDA-MB231) were larger than endosomes observed in noncancerous epithelial cells (MCF10A). These enlarged endosomes showed prolonged and amplified EGF-mediated EGFR activation. Furthermore, Rab4A depletion in MCF10A cells demonstrated similarly enlarged endosomes but did not exhibit increased EGF-mediated signal activation. The purpose of this investigation is to study the role of Rab4, specifically isoforms a and B, on the role of endocytic trafficking of EGFR and TfR in breast cancer cell proliferation, migration, and invasiveness. Current progress in this investigation using a cell line panel real-time polymerase chain reaction (RT-PCR) assay revealed that compared to MCF10A, MDA-MB231 has increased expression of Rab 4B mRNA and decreased expression of Rab 4A mRNA. Similarly, a Luminal a breast cancer cell line (T47D) has increased expression of Rab 4B and decreased expression of Rab 4A mRNA. Compared to the MCF10A cell line, a Luminal-HER2+ cell line (AU565) and a triple-negative breast cancer cell line (MDA-MB 436) has low expression of both Rab 4A and Rab 4B mRNA levels. Future directions for this investigation will involve generating single and dual knockdowns of Rab 4A/B to assess their effect on endosome size, EGFR activation, and associated cell proliferation and invasiveness in a variety of human breast cancer cells (see above). Repeat studies and analyses will be conducted with individual and dual overexpression of isoforms Rab4A/B. By assessing the effect of Rab4 isoforms on the endocytic pathway, the role of endosomal morphology and function in breast cancer can be further elucidated. Furthermore, future advancements can be made towards understanding the process by which cancer cells hijack the endocytic pathway to proliferate and survive especially in unconducive environments. Moreover, understanding the endocytic pathway can provide insights as to why some cancer cells respond to receptor-mediated targeted therapy while others do not respond as well.

P442/B452

Expanding the Realm of Small GTPase Function: Evidence for Rab40b/Cul5 Mediated Rap2 Regulation during Cell Migration.

E. D. Duncan, E. Linklater, R. Prekeris; University of Colorado an schutz Medical Campus, Aurora, CO.

One of the most fundamental questions in cell biology is how cells migrate through three-dimensional (3D) spaces. A defining feature of cell migration is the formation of actin-rich protrusions at the leading edge that are necessary for remodeling of the extracellular matrix (ECM). Extension of these actin-rich

protrusions, known as invadopodia, combined with the targeted secretion of matrix metalloproteinases (MMPs) facilitate degradation of the ECM, allowing cells to migrate and invade through their surrounding environment. However, what remains poorly understood is how cells coordinate MMP secretion and actin polymerization during the formation and extension of invadopodia. Our lab has identified Rab40b as a regulator of invadopodia formation, targeted MMP secretion, and cell migration. Rab40b is unlike any other small GTPase because in addition to the canonical Rab domain, it also contains a Suppressor of Cytokine Signaling (SOCS) domain, a binding motif known to act as a bridge between E3 Ubiquitin (Ub) Ligases and protein substrates. In this study we demonstrate that Rab40b binds to Cullin5 (Cul5), a known E3 Ub Ligase module critical for protein ubiquitylation and degradation. We have also identified Rap2 as a putative substrate of the mammalian Rab40b/Cul5 complex. Importantly, the Rap family of small GTPases, including Rap2, have been linked to the regulation of cell-cell adhesions and actin cytoskeleton dynamics. Here we show that Rab40b/Cul5 binds and regulates Rap2 by mediating its mono-ubiquitylation. Interestingly, we demonstrate that inhibition of Rap2 mono-ubiquitylation leads to endocytic removal from the plasma membrane and rapid lysosomal degradation, thus, terminating Rap2 signaling. Based on our preliminary data, we propose that Rab40b is a dual-functioning Rab GTPase, given its co-regulation of vesicular MMP trafficking as well as Rap2 activity, and such co-regulation plays a key role in driving 3D cell migration and invasion. Results gained from this study will broaden our scientific understanding not only of Rab GTPase function but will also help uncover novel machinery governing cell migration.

P443/B453

Stochastic Activation and Bistability in a Rab GTPase Regulatory Network.

U. Bezeljak[1], H. Loya[2], T. Saunders[3], **M. Loose**[1]; [1]Institute of Science and Technology Austria, Klosterneuburg, AUSTRIA, [2]IIT, Bombay, INDIA, [3]National University Singapore, Singapore, SINGAPORE.

Rab GTPases are the central regulators of intracellular traffic. Their function relies on their conformational change triggered by nucleotide exchange and hydrolysis. While this switch is well understood for an individual protein, how Rab GTPases collectively transition between different states is not known. Here, we combine in vitro reconstitution experiments with stochastic reaction-diffusion modeling to study the non-equilibrium properties of the minimal Rab5 activation network. We find that collective switching of Rab5 relies on a positive feedback and is triggered by intrinsic noise due to low amounts of Rab5[GDP] preexisting on the membrane. We show that this inactive population is not only the source of stochastic behavior of this biochemical circuit, but can act as a control parameter for Rab5 activation.

P444/B454

Determining the Effects of *Legionella Pneumophila* -Side Family Effector Proteins on Host Endocytic Recycling Systems.

S. C. Allgood; University of Delaware, Newark, DE.

Legionella pneumophila is an opportunistic, intracellular pathogen responsible for Legionnaire's disease in humans. Upon infection, *L. pneumophila* forms the *Legionella* Containing Vacuole (LCV) to shield itself from host immune responses. From the LCV, *L. pneumophila* use a T4SS secretion system to secrete over 320 effector proteins into the host cell. It Is able to avoid phagocytosis by interfering with transport of "(ER)-derived vesicles" from ER to Golgi and using those vesicles to coat the outside LCV. These proteins

are essential for targeting normal host pathways to optimize the environment for *L. pneumophila* replication. One pathway that is disrupted after *L. pneumophila* infection is the endocytic recycling pathways. This system can use two distinct recycling pathways, a slow or fast route which use host cell Rab-GTPases to transport endosomes containing proteins and nutrients to the plasma membrane. Rab11a is an essential RabGTPase in the slow recycling pathway, and it works in concert with additional adapter proteins such as FIP1A, which aid in transferrin recycling. The Neunuebel lab has observed defects in transferrin recycling during *L. pneumophila* infection. We have identified an interaction between Rab11a and SidE family proteins. SdeA, a protein in this family, has been shown to ubiquitinate certain RabGTPases. We have found that SdeC interacts with Rab11a and localizes in close proximity to it. Further investigation revealed a stronger interaction between SdeC and Rab11a-FIP1A. This may be through ubiquitination of Rab11a-FIP1A by SdeC. In addition to Rab11a-SdeC interactions, were are interested in exploring the role of a family of Rab adapter proteins known as FIPs in recycling during infection and present data that FIP binding to Rab11 may be disrupted through SdeC. Overall we hope to understand the role of endocytic recycling pathways during intracellular bacterial infection.

P445/B455

Roles and Regulation of the Phosphatidylinositol 4-kinase Pik1 at the *Trans*-golgi Network.

C. M. Highland, J. C. From me; Cornell University, Ithaca, NY.

In eukaryotes, the *trans*-Golgi network (TGN) is a central hub for vesicle-mediated protein trafficking. At the *Saccharomyces cerevisiae* TGN, the small GTPases Arf1 (ARF1 homologue) and Ypt31 (Rab11 homologue) collaborate with an essential pool of phosphatidylinositol 4-phosphate (PI4P) to recruit vesicle coats, transport motors, and tethering proteins to nascent secretory vesicles. The conserved PI 4-kinase Pik1 (PI4KIIIβ homologue) generates PI4P at the TGN, and although its catalytic function is well-characterized, its interactions with other TGN regulatory factors are not. Using a combination of imaging and in *vitro* protein-protein interaction assays, we have found that Pik1 is recruited to the TGN by Arf1. Further, once there, Pik1 helps control recruitment of several downstream Ypt31 effectors, likely through its established binding interaction with Ypt31, to temporally regulate secretory vesicle formation. These results, together with ongoing structural work, paint a clearer picture of the mechanisms by which Pik1 works alongside Arf1 and Ypt31 to choreograph TGN function.

P446/B456

Mechanosensory Dendrite Termination and Refinement in *C. Elegans*.

M. Gallegos, 94542, A. Hosseini, D. Newport, D. Decena, L. Serra, P. Das, C. Ndungu-Case; Cal State University, East Bay, Hayward, CA.

Exuberant axon and dendrite growth followed by stereotyped shortening is common during the development of neural circuits in most animals including humans. Despite the critical importance of this process, the underlying molecular mechanisms remain poorly understood. The posterior mechanosensory neuron (PLM) in *C. elegans* also follow this pattern of growth. PLM initially extends beyond its termination zone leading to overlap with its anterior counterpart, ALM. Its dendrite then retracts such that ALM and PLM divide the animal's body into anterior and posterior sensory domains ensuring proper response to localized touch. Importantly, dendrite termination and stereotyped shortening occurs just below the body surface during early larval development so PLM morphology can be measured in developing animals to identify important genes. Genes identified can then be monitored

at the sub-cellular level by tagging with fluorescent markers. In other words, PLM provides an excellent model for studying neurite termination and stereotyped shortening at sub-cellular resolution. My work first identified two genes conserved from yeast to humans: *sax-1* (an NDR kinase) and *sax-2* (a conserved scaffold protein). Null mutations in either gene lead to PLM overextension. Double mutant analysis indicates they function in the same pathway and a developmental time course comparing WT and *sax-2* mutants reveals a specific defect in the regulated shortening step of PLM dendrite development. More recently, we find that the *sax-1/sax-2* pathway may regulate polarized exocytosis. The *rab-10* GTPase and its GAP, *tbc-4*, also leads to PLM overextension and the *rab-10* null is **not** enhanced in the absence of *sax-1* or *sax-2*. Interestingly, endocytosis may also control PLM dendrite termination. *unc-11,* a worm ortholog of phosphatidylinositol binding clathrin assembly protein (PICALM) also leads to PLM overextension. PICALM functions in clathrin-coated endocytosis and VAMP recycling. Here, double mutant analysis indicates that *unc-11* functions in parallel to *sax-1* and *sax-2*. To better understand how these genes control PLM dendrite morphology, we have been fusing these genes to fluorescent markers using a CRISPR knock-in strategy. In preliminary work, we observe a small number of SAX-2::GFP puncta near the dendrite tip. We anticipate a fuller understanding of the genes that contribute to the establishment and maintenance of neural circuits will help guide rational design of therapies to aid people with spinal cord injuries or neurodegenerative disorders.

The an alysis of Rab32/38 Mediated Membrane Traffic in Macrophage and Osteoclast.

K. Tokuda[1], K. Noda[2], Y. Yamamoto[2], Y. Usami[3], K. Hirose[3], S. Toyosawa[3], M. Fukuda[4], T. Noda[2]; [1]Center for Frontier Oral Science, Graduate School of Frontier Biosciences, Osaka University, Osaka, JAPAN, [2]Center for Frontier Oral Science, Graduate School of Dentistry, Osaka University, Osaka, JAPAN, [3]Department Oral Pathology, Graduate School of Dentistry, Osaka University, Osaka, JAPAN, [4]Laboratory of Membrane Trafficking Mechanisms, Graduate School of Life Sciences, Tohoku University, Miyagi, JAPAN.

Osteoclasts (OCLs) are multinucleated giant cells formed by repeated differentiation and fusion from the bone-marrow macrophages (BMMs). OCLs resorb bone by secreting vesicles and acids containing various proteases and enzymes such as tartrate-resistant acid phosphatase (TRAP) into the resorption pits formed on the bone surface. BMMs and OCLs are characterized of their dynamic inter cellular membrane traffic, however little is known about the underlying this mechanism. To understand the membrane how membrane traffic mechanism is involved in OCLs function, we focused on the Rab protein which is a regulator of membrane traffic. Firstly, we checked expression levels of all Rab proteins in BMMs and OCLs by using DNA microarray analysis. As a result, Rab38 expression levels significantly increased in OCLs. We focused on Rab38 and Rab32 which is paralogue of Rab38. To elucidate the physiological role of Rab32 and Rab38 in OCLs, we created Rab32 and Rab38 double knockout mice (Rab32/38 DKO mice) by using the Crispr/CAS9 system. Rab32/38 DKO mice have a phenotype with red eyes and ivory coat color. Then we analyzed the femur of 8-week-old wild type mice and Rab32 / 38 DKO mice by 3D micro CT analysis. As a result, Rab32 / 38 DKO mice had increased bone mass in femur was observed in the cancellous bone area. We confirmed whether deletion of Rab32 and Rab38 affects differentiation and bone resorption by using primary bone marrow-derived cultures. As a result, Rab32 and Rab38 deletion did not affect differentiation efficiency but decreased TRAP secretion during bone resorption. As a result of immunofluorescence staining in OCLs, Rab32 and Rab38 were co-localized on novel lysosomal like membranous organelles in BMMs and OCLs. Surprisingly this organelle dynamically

engulfed and degraded other organelles such as endosomes and mitochondria during differentiation process toward OCLs. Our findings indicate that Rab32 / 38 positive organelle is a novel lysosome-like organelle in OCLs. In addition, Rab32 / 38 positive organelles was involved in the biosynthesis of TRAP during bone resorption and have interesting properties that are also involved in endocytic pathway. OCLs function in bone resorption should be supported through these pathways.

P448/B458

Evidence That Rab18 and Class II Arfs Regulate Lipolysis and Adipose Triglyceride Lipase Association with Lipid Droplets in Hela Cells.

J. F. Presley[1], S. Yilmaz Dejgaard[2]; [1]McGill University, Montreal, QC, CANADA, [2]Near East University, Nicosia, CYPRUS.

Rab18 is a small GTPase that associates with lipid droplets, endoplasmic reticulum and other membranes of the secretory and endocytic pathways. While it likely has multiple functions on lipid droplets, both anabolic and catabolic, one proposed function is regulation of lipolysis. There is evidence for involvement of Rab18 in autophagy (Biochem. Biophys. Res. Commun 486(3):738-43; 2017) but whether it regulates lipid droplet catabolism via recruitment of cytoplasmic lipase is still unclear. We provide evidence that, in HeLa cells, Rab18 plays a role upstream of the cytosolic lipolytic enzyme adipose triglyceride lipase (ATGL). Furthermore, our evidence implicates elements of the Arf/GBF1 machinery in recruitment of ATGL by Rab18 and suggests a possible role for Class II Arfs. In HeLa cells loaded with 100 µM oleic acid for 24 hrs., we find that Arf4-GFP is specifically accumulated on the subset of lipid droplets associated with cerulean-Rab18 or mCherry-Rab18. This association is lost within 5 minutes of treatment with 5 µg/ml of the drug brefeldin A, which targets GBF1 and other Sec7-domain containing Arf exchange factors. ATGL-GFP is also recruited to lipid droplets, but is lost more slowly after treatment with 5 µg/ml brefeldin A. Loss of ATGL-GFP from lipid droplets is not significant after 5 min. Of BFA treatment, and significant but partial loss ($p < 0.001$) occurs after 1 hr treatment. Loss of detectable association of ATGL-GFP with lipid droplets was found 4 hrs after brefeldin a treatment. When the dominant negative GDP-locked cerulean-Rab18-S22N is overexpressed, GFP-ATGL and Arf4 are lost from the surface of lipid droplets similarly to BFA treatment. These results suggest a role for Rab18 in recruiting ATGL to lipid droplets.

Membrane Fission and Coat Proteins

P449/B459

Membrane Deformation Ability of the an kyrin Repeat and KH Domain-containing Protein 1 (ANKHD1) and Its Involvement in the Early Endosome Enlargement.

M. Kitamata, **S. Suetsugu**; NAIST, Ikoma, JAPAN.

Ankyrin-repeat domains (ARDs) are conserved in large numbers of proteins. ARDs are composed of ankyrin repeats (ANKs). The number of repeats varies among ARDs, and the sequence of ANKs often adopt curved structures reminiscent of the Bin-Amphiphysin-Rvs (BAR) domain, which is the dimeric membrane scaffold for membrane tubulation. BAR domains sometimes have amphipathic helices that enable membrane scission for vesicle formation. However, it is unclear whether ARD-containing proteins exhibit similar membrane deformation and scission properties. We screened the membrane deformation abilities of the highly expressed ARD proteins in vitro. We found that the ARD of ankyrin

repeat and KH domain-containing protein 1 (ANKHD1) dimerizes and efficiently deforms membranes into tubules and vesicles. ANKHD1 contains 25 ANKs that are divided into two groups: the first 15 ANKs and the latter 10 ANKs. The first 15 ANKs can form a dimer, and the latter 10 ANKs enable membrane tubulation and vesiculation. These 10 ANKs had an adjacent amphipathic helix and were predicted to have a curved structure with a positively charged surface, analogous to BAR domains. Mutations in positively charged amino acid residues and the deletion of the amphipathic helix abolished the membrane vesiculation ability. Interestingly, the dimeric 25 ANKs displayed significantly higher vesiculation ability than the 10 ANKs. Knockdown and localization of ANKHD1 suggested its involvement in the negative regulation of early endosome enlargement owing to its membrane deformation ability. These results indicate that ANKHD1 causes vesiculation of the early endosomal membranes in a manner similar to the BAR domain protein.

P450/B460

Septin Recruitment of Contractile Acto-myosin Cages to Vesicle Membranes Drives Regulated Exocytosis in Exocrine Glands of Live Mice.

S. Ebrahim, 20892, M. Weiss, D. Chen, R. Weigert, 20892; NCI/NIH, Bethesda, MD.

The constant remodeling of cellular membranes into various curved configurations is a requisite for myriad biological processes ranging from cytokinesis to intracellular trafficking. To elucidate the molecular machines and processes driving membrane remodeling under physiological conditions, we use the process of regulated exocytosis in the salivary gland of live mice as a model system. In this model, we recently showed that 1) F-actin and non-muscle myosin (NMII) form polyhedral-like lattices around large membrane-bound secretory granules (SGs) undergoing exocytosis, and 2) use contractility and polymerization-forces to push the SG membrane into the plasma membrane (integration), allowing content release into the extracellular space. This study raised new questions regarding how this unique acto-myosin network is both recruited and organized to perform its key function. To address this, we explored the role of septins, which we identified in a screen of purified SGs, as potential candidates, based on their known abilities to sense/generate micron-scale membrane curvature, interact with the actin cytoskeleton and recruit NMII. We found, strikingly, via immunofluorescence and super-resolution microscopy that septins 2, 6 and 7 (SEPT2, SEPT6 and SEPT7) are in fact present on the surface of fused SGs, where they each organize into cage-like lattices. Using transgenic mice expressing GFP-NMIIA, we show that NMIIA colocalizes with the SEPT2 and that pharmacological inhibition of SEPT2 results in a significant decrease in the presence of activated NMII and of myosin light chain kinase (MLCK) on actin-coated fused SGs. Conversely, disruption of F-actin assembly on the SG surface leads to an expansion in SG size without impairing NMII or septin recruitment. Finally, we find that the dynamics of integration and the levels of acto-myosin on the SG surface are both compromised in mice lacking SEPT7 expression in salivary gland secretory cells. Based on our data, we propose that the newly observed septin-lattices: 1) provide a molecular scaffold to recruit and curve acto-myosin filaments populating the surface of SGs, and 2) are needed for the activation of NMII, likely through MLCK-mediated phosphorylation, which ultimately drives SG exocytosis. Finally, the pattern of organization of both septins and NMII on the SG surface provide new structure-function insights into the molecular mechanisms driving membrane remodeling in *vivo*.

The Cryo-em Structure of the Snx-bar Mvp1 Tetramer.

D. Sun[1], N. V. Varlakhanova[1], B. A. Tornabene[1], R. Ramachandran[2], P. Zhang[1], **M. G. J. Ford**[1]; [1]University of Pittsburgh School of Medicine, Pittsburgh, PA, [2]Case Western Reserve University, Cleveland, OH.

Sorting nexins (SNX) are a diverse family of lipid-binding proteins with pivotal roles in trafficking and signaling processes. The SNX-BAR subfamily has critical membrane-remodeling functions, particularly at the endosome. The SNX-BAR minimal module, consisting of a tight association of a PI3P-binding PX domain and a curvature generating BAR-domain, has been shown to be a dimer, formed by an extensive BAR-BAR interface. We use cryo-electron microscopy (cryo-EM) to determine the structure of the full-length SNX-BAR Mvp1 to a global resolution of 4.2 Å. Surprisingly, Mvp1 is an autoinhibited tetramer, consisting of a dimer of dimers, wherein both concave membrane-binding BAR dimer surfaces are sequestered into the interior of the tetramer and the lipid-binding sites of the PX domains are occluded. The N-terminal low-complexity region (~100 residues) of Mvp1 is disordered but plays a critical role in tetramerization, as its removal results in constitutive dimers that exhibit enhanced membrane association in *vivo* and increased membrane binding and tubulation activity in *vitro*. Tetramerization can also be abolished by point mutations within the PP_{II} loop of the Mvp1 PX domain. Membrane binding and remodeling by Mvp1 therefore requires unmasking of the PX and BAR domain lipid-interacting surfaces, which are occluded by tetramerization promoted by the N-terminus. The functional importance of the low-complexity N-terminus in regulation of tetramerization provides an explanation for why existing SNX-BAR crystal structures, generated from minimal PX-BAR constructs, are invariably dimeric. This work reveals a novel tetrameric configuration of a SNX-BAR protein that provides critical insight into SNX-BAR function and regulation.

The Timing and Localization of ESCRTS in Membrane Bending and Scission: Lessons from Studying Single Virions of HIV-1.

D. S. Johnson, M. Bleck, M. S. Itano, **S. M. Simon**; Rockefeller University, New York, NY.

Host cellular proteins that are members of the Endosomal Sorting Complexes Required for Transport (ESCRT) family are involved in many cellular processes that require bending of the membrane away from the cytosol. These include the formation of multivesicular bodies, cell scission at cytokinesis, repair of plasma and nuclear membrane, release of ectosomes and budding of retroviruses. Some hypotheses posit that the ESCRT-IIIs drive the bending of the membrane and some hypotheses posit that ESCRT-IIIs drive the membrane scission. We used the assembly of HIV-1, which occurs on the surface of cells as a model system for high resolution imaging of the timing and localization of the recruitment of ESCRT-III. We have quantified timing, the number and the localization of ESCRT-IIIs in HIV-1 while monitoring membrane bending and scission. The ESCRT-III arrive after the recruitment of the genome, and many minutes after the recruitment of the coat protein Gag and after the initiation of bending of the membrane This recruitment of ESCRT-IIIs is transient. They arrive roughly 60 seconds before scission, are at the site of virion assembly for 40 seconds, and can no longer be detected 20 seconds prior to scission. Using super-resolution microscopy, we find the ESCRT-IIIs are only recruited to the neck of the nascent virion with ~100 molecules recruited, enough to form one or two rings. The results indicate that ESCRT-IIIs play a critical role in the final steps of assembly, but they themselves are not responsible for initiating bending and they may not be providing the force for scission.

P453/B463

The Proppin Wipi1 Promotes Membrane Fission for Protein Exit from Endosomes.

M. De Leo[1], J. Klumperman[2], N. Gopaldass[1], D. Moreau[3], V. Comte-Miserez[1], A. Mayer[1]; [1]University of Lausanne, Epalinges, SWITZERLAND, [2]University Medical Center, Utrecht, NETHERLANDS, [3]University of Geneva, Geneva, SWITZERLAND.

Endosomal and lysosomal compartments exchange material through tubulo-vesicular carriers, which recruit cargo by coat complexes such as retromer, retriever or commander. How these carriers separate from the endosomes is poorly understood. Here, we show that the PROPPIN family protein WIPI1 is required for protein exit from endosomes towards Golgi, lysosomes and plasma membrane. It promotes the formation and fission of endosomal membrane tubules through its two phosphoinositide binding sites. WIPI1 transport activity requires the lipid $PI(3,5)P_2$, one of the two phosphoinositide binding sites of WIPI1, and the formation of an amphipathic α-helix between these lipid binding sites. Inactivation of any one of these three features, which are all critical for the in vitro membrane fission activity of the yeast WIPI1 homolog Atg18, leads to a strong enlargement of endosomal compartments. The organelles then accumulate micrometer-long membrane tubules carrying endosomal markers and cargo proteins. WIPI1 may thus be implicated in membrane fission in multiple endosomal protein exit pathways, suggesting that membrane fission activity may be a general feature of PROPPIN family proteins.

P454/B464

Curvature Induction and Sensing of the F-BAR Protein Pacsin1 on Lipid Membranes Via Molecular Dynamics Simulations.

M. I. Mahmood[1], H. Noguchi[2], **K. Okazaki**[1]; [1]Institute for Molecular Science, Okazaki, JAPAN, [2]Institute for Solid State Physics, Kashiwa, JAPAN.

F-Bin/Amphiphysin/Rvs (F-BAR) domain proteins play essential roles in biological processes that involve membrane remodelling, such as endocytosis and exocytosis. It has been shown that such proteins transform the lipid membrane into tubes. Notably, Pacsin1 from the Pacsin/Syndapin subfamily has the ability to transform the membrane into various morphologies: striated tubes, featureless wide and thin tubes, and pearling vesicles. The molecular mechanism of this interesting ability remains elusive. In this study, we performed all-atom (AA) and coarse-grained (CG) molecular dynamics simulations to investigate the curvature induction and sensing mechanisms of Pacsin1 on a membrane. From AA simulations, we show that Pacsin1 has internal structural flexibility. In CG simulations with parameters tuned from the AA simulations, spontaneous assembly of two Pacsin1 dimers through lateral interaction is observed. Based on the complex structure, we show that the regularly assembled Pacsin1 dimers bend a tensionless membrane. We also show that a single Pacsin1 dimer senses the membrane curvature, binding to a buckled membrane with a preferred curvature. These results provide molecular insights into polymorphic membrane remodelling.

P455/B465

Induced Nanoscale Curvature Localizes Endocytic Machinery and Rescues Clathrin Knockdown.

R. Cail[1,2], S. Dhuey[2], S. Cabrini[2], D. G. Drubin[1]; [1]UC Berkeley, Berkeley, CA, [2]Lawrence Berkeley National Laboratory, Berkeley, CA.

Clathrin-mediated endocytosis (CME), the principal route of receptor internalization in eukaryotes, requires rapid, coordinated membrane restructuring on the scale of 50-100 nanometers to produce spherical vesicles from flat membrane. Here, we have used a combination of electron beam lithography (EBL) and UV-nanoimprint lithography (UV-NIL) to create a set of glass-like nanofabricated substrates, suitable for most optical microscopy techniques, with curved nanoscale features of diameters ranging from 50-1000 nanometers to mimic the stages of CME progression and beyond. We have imaged fluorescently tagged endocytic proteins from distinct stages of CME in SKMEL2 and MDA cells as they undergo endocytosis. We found that proteins from across stages of endocytosis are localized to sites of high curvature and that the lifetimes of early endocytic proteins AP2 and clathrin are shortened significantly as curvature increases. We found that the protein Epsin1, which binds directly to PIP_2 and generates curvature early during endocytosis, strongly localizes to sites of high curvature but does not turn over for the duration of our imaging, indicating it may be dispensable in the presence of induced curvature. The vesicular fission protein dynamin2 exhibits a two-fold increase in turnover rate as curvature increases, indicating that curvature-induced localization of endocytosis corresponds to an increased rate of CME. Together, these data suggest that generation of curvature may be rate-limiting in CME. To test whether exogenous curvature could rescue a defect in endocytosis, we knocked down clathrin using siRNA. Curvature-dependent localization of AP2 occurs in clathrin knockdown cells. We also found that curvature rescues the localization and turnover of dynamin2 in the background of both clathrin knockdown by siRNA and treatment by pitstop2, an inhibitor of CME that halts curvature progression. To test whether exogenous curvature rescues productive endocytosis from clathrin knockdown, we performed transferrin uptake assays and found that the presence of exogenous curvature partially rescues transferrin uptake in the context of 80% depletion of clathrin by siRNA. These data are consistent with clathrin acting as a Brownian ratchet, locking in the energetically costly membrane curvature as CME progresses, and that the presence of induced curvature may bypass this energetically costly step.

Polarity in Development

P456/B467

SGEF, a RhoG-specific GEF, Associates with the Scribble Polarity Complex and Regulates Cell-cell Junctions, Contractility and Lumen Formation in Epithelial Cells.

S. Awadia[1], F. Huq[2], T. R. Arnold[3], S. Goicoechea[1], Y. Sun[4], T. Hou[4], G. Kreider-Letterman[1], P. Massimi[5], L. Banks[6], E. J. Fuentes[4], E. J. Fuentes[4], A. L. Miller[2], **R. Garcia-Mata**[1]; [1]University of Toledo, Toledo, OH, [2]University of Michigan, an n Arbor, MI, [3]University of Michigan, Toledo, MI, [4]University of Iowa, Iowa City, IA, [5]4International Centre for Genetic Engineering and Biotechnology, Trieste, ITALY, [6]International Centre for Genetic Engineering and Biotechnology, Trieste, ITALY.

The canonical Scribble polarity complex is implicated in regulation of epithelial junctions and apical polarity. However, little evidence is available regarding the molecular mechanisms that control its function. Here, we show that SGEF (SH3-containing Guanine nucleotide Exchange Factor), a RhoG-

specific GEF, interacts simultaneously with Scribble and Dlg1, and functions as a bridge that mediates the formation of a ternary complex. Our results show that SGEF is recruited to apical junctions in a Scribble-dependent fashion and functions in the regulation of actomyosin-based contractility and barrier function at tight junctions as well as E-cadherin-mediated formation of adherens junctions. Surprisingly, SGEF does not control the establishment of polarity. However, in 3D cysts, SGEF regulates the formation of a single open lumen. Interestingly, SGEF's nucleotide exchange activity regulates the formation and maintenance of adherens junctions, and in cysts, the number of lumens formed, whereas, SGEF's scaffolding activity is critical for regulation of actomyosin contractility and lumen opening. We propose that SGEF plays a key role in coordinating junctional assembly and actomyosin contractility by bringing together Scribble and Dlg1 and targeting RhoG activation to cell-cell junctions.

Cytokinetic Bridge Triggers *De Novo* Lumen Formation in *Vivo*.

L. I. Rathbun[1], E. G. Colicino[2], S. Coyne[3], N. S. Reilly[4], G. Erdemci-Tandogan[1], A. Garrastegui[1], J. Freshour[1], J. Manikas[1], P. Santra[5], M. Manning[1], J. Amack[5], H. Hehnly[1]; [1]Syracuse University, Syracuse, NY, [2]University of Michigan Medical School, an n Arbor, MI, [3]SUNY Geneseo, Geneseo, NY, [4]University of Rochester, Rochester, NY, [5]SUNY Upstate Medical University, Syracuse, NY.

Multicellular rosettes are polarized, transient epithelial structures that serve as intermediates during the formation of diverse organs. We have identified a unique contributor to rosette formation in zebrafish Kupffer's Vesicle (KV) that requires cell division, specifically the final abscission stage of mitosis. KV utilizes a rosette as a prerequisite before forming a central lumen surrounded by ciliated epithelial cells. Our studies identify that KV-destined cells remain interconnected by cytokinetic bridges that position at the rosette's center, acting as a landmark for directed Rab11 vesicle motility to deliver an essential cargo for lumen formation, CFTR. We found that prematurely severing a bridge using laser ablation or inhibiting abscission using Rab11 optogenetic clustering results in disrupted lumen formation. We present a model in which mitotic cells within the KV rosette strategically place their cytokinetic bridges at the site of future lumen formation, where Rab11-associated vesicles transport CFTR to aid in lumen establishment.

Tracking Stereociliary Bundle Establishment in Utricular Explants of the Mouse Inner Ear.

Y. Tona, D. Wu; NIH/NIDCD, Bethesda, MD.

The orientation of the stereociliary bundle (hair bundle) on the apical surface of sensory hair cells (HCs) determines their directional selectivity. A hair bundle is comprised of a kinocilium, tethered by a staircase of microvilli known as stereocilia. Only when the hair bundle is deflected towards its kinocilium, the tallest rod in the bundle, results in opening of the mechano-transduction channels on the tips of the stereocilia and activates (depolarizes) the HC. Because of this property of the hair bundle, each sensory organ of the inner ear exhibits a defined hair bundle orientation pattern that is tailored for its function. Notably, in each of the two vestibular maculae, the utricle and saccule, hair bundles can be divided into two regions of opposite orientations by a line of polarity reversal (LPR). Previously, we have shown that the LPR is established by the restricted expression of a transcription factor Emx2 to one side of the LPR and thus changes the hair bundles within that region from the default position by 180 degrees. We investigated whether there is a fundamental difference in hair bundle establishment

between Emx2+ and Emx2- HCs by live imaging of embryonic utricular cultures, in which HCs are tdTomato-positive and centrioles are GFP-positive. Hair bundle establishment is thought to be initiated by the mother centriole docking at the apical HC surface to serve as the basis for the kinocilium. After kinocilium formation, it migrates to its destinated position in the periphery before the stereocilia staircase is built around it. We distinguished the two GFP-positive centrioles based on the fact the mother centriole is more apically located than the daughter centriole. Our result showed that the daughter centriole always migrated to the periphery from the center of the HC ahead of the mother centriole, suggesting that the daughter centriole may be guiding the mother centriole to its destinated location. Additionally, we did not find any obvious difference in the trajectory of centrioles to their destinated location between Emx2+ and Emx2- HCs, other than the fact that their final positions are on opposite side of the HC. These results suggest that the cellular machinery that guides directed centriole movements has already been established by downstream effector(s) of Emx2 prior to kinocilium migration to the periphery.

An Unexpected Role for the LGN Homolog AGS3 in Promoting Planar Divisions during Epidermal Morphogenesis.

C. Patino Descovich[1], K. Lough[1], J. Yom[2], D. Spitzer[3], S. E. Williams[1]; [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]National Institute of Allergy and Infectious Diseases, Bethesda, MD, [3]University of California, Berkeley, Berkeley, CA.

Asymmetric cell divisions, whereby progenitor cells divide to give rise to daughter cells that adopt different fates, are an important mechanism to promote cellular diversity. An evolutionarily conserved complex of polarity proteins directs asymmetric cell divisions, including the core scaffolding protein LGN (Gpsm2). The *Drosophila* LGN ortholog Pins plays a key role in both the positioning and orientation of the mitotic spindle in neuroblasts, ensuring the unequal inheritance of fate determinants that induces different daughter cell fates. In basal cell progenitors in developing stratified epithelia, we have shown that LGN localizes asymmetrically to the apical cortex and promotes perpendicular divisions. Epidermal LGN loss leads to elimination of perpendicular divisions, decreased differentiation and impaired barrier function, resulting in neonatal lethality. This highlights the critical importance of maintaining a proper balance between planar (symmetric) and perpendicular (asymmetric) divisions. While the complex of proteins that promotes perpendicular divisions has been well characterized, much less is known about what orchestrates planar divisions. One candidate is the LGN homolog AGS3 (Gpsm1), although whether AGS3 possesses intrinsic spindle orienting activity remains controversial. Surprisingly, our data show that AGS3 does play an important role in spindle orientation in the developing epidermis, and in fact appears to oppose LGN function. Loss of AGS3 increases perpendicular (asymmetric) divisions, while AGS3 overexpression increases the proportion of planar divisions. However, because AGS3 does not appear to be detectable or polarized at the cell cortex in mitotic basal cells—as previously shown in neuronal progenitors—we hypothesize that AGS3 may impact spindle orientation indirectly by competing with LGN for downstream binding partners. Supporting this, we observe that AGS3 knockdown increases LGN cortical intensity, while AGS3 overexpression disrupts LGN cortical localization. Finally, we have recently described a phenomenon termed “telophase reorientation” (https://doi.org/10.1101/668244), in which basal cells that enter anaphase at oblique angles correct to either planar or perpendicular during telophase. Using live imaging of epidermal explants, we show that LGN plays a maintenance role during telophase, promoting perpendicular reorientation. Interestingly,

AGS3 also appears to function during telophase reorientation, as a higher percentage of oblique divisions reorient to perpendicular during telophase upon AGS3 loss. Together, these data suggest that the two vertebrate Pins orthologs play opposing roles in spindle orientation in the developing epidermis.

P460/B471

The Role of Bloc-1 in Planar Cell Polarity.

C. Tower-Gilchrist, 30322[1], V. Faundez[2], P. Chen[2]; [1]Emory University, SON, Atlanta, GA, [2]Emory University, Sch of Med, Atlanta, GA.

Planar cell polarity (PCP) regulates coordinated cellular polarity along an axis parallel to the plane of the tissue. PCP signaling is critical for developmental functions. Defects in PCP can result in mis-orientation of hair cell stereociliary bundles in the cochlear epithelium, deafness and neural tube closure. A key feature of PCP is the asymmetrical location of core PCP proteins, Vangl2 and Frizzled. Previously we showed that Adaptor Protein Complex -3 (AP-3) plays a role in the Vangl2 trafficking and PCP. However, the molecular mechanisms that regulate the sorting of PCP transmembrane proteins is not fully understood. Here, we investigate the role of biogenesis of lysosome-related organelles complex-1 (BLOC-1) in PCP and Vangl2 trafficking. To elucidate the underlying mechanisms of Vangl2 sorting, we evaluated the distribution of Vangl2 in cochlea from loss of function BLOC-1 mice, $Dtnbp1^{sdy/sdy}$ and $Pldn^{pa/pa}$. We observed a reduced membrane localization of Vangl2 in $Pldn^{pa/pa}$. We show notable PCP defects including mis-oriented hair cell sterociliary bundles and extra hair cell rows in these mice. These finding strongly suggest that BLOC-1 mediated endosomal pathways are essential for PCP sorting and membrane targeting of Vangl2.

P461/B472

Hematopoietic Stem Cells Polarise in Contact with Bone Marrow Stromal Cells by Engaging Cxcr4 Receptors.

T. Bessy[1], B. Souquet[1], B. Vianay[1], L. Faivre[2], A. Schaeffer[1], T. Jaffredo[3], J. Larghero[2], L. Blanchoin[1], S. Brunet[1], **M. Thery**[1]; [1]CytoMorpho Lab, Hopital Saint Louis, Paris, FRANCE, [2]APHP, Hopital Saint Louis, Paris, FRANCE, [3]Institut de Biologie Paris Seine, Paris, FRANCE.

Hematopoietic Stem Cells (HSC) are located in the bone marrow, where they regulate the permanent production and renewal of all blood cell types. Their molecular and cellular micro-environment, called the niche, is a potent regulators of HSC proliferation and differentiation. However, the cellular mechanism of HSC interaction with the stromal cells of the niche has not been investigated in details. Here we used microfluidic compartments filled with hydrogels to reconstitute a bone-marrow on a chip as well as microwells to enforce a lasting contact between doublets formed by HSC and individual stromal cells. We found that HSC can become highly polarized in contact with niche stromal cells. They assembled a single, focused and thight anchorage point on the stromal cell from which they adopted the shape of a leaf of a wild cherry tree. As in the case of the immune synapses formed by lymphocytes, the centrosome was located in the proximity of the anchorage point. The entire microtubule network emmanated from the centrosome and appeared to keep the nucleus at a distance. HSC capacity to polarise was cell-type specific since it could be observed on endothelial cells and osteoblasts but not on fibroblasts. In addition, the frequency of polarised cells decreased with the degree of cell differentiation. Finally, we found that although ICAM, VCAM and CXCR4 were present in the anchorage point, only CXCR4 was intrinsically capable to trigger HSC polarisation. Altogether these results revealed a novel

interaction and polarisation mechanism of HSC which might be instrumental in the regulation of their fate.

P462/B473

Glutathione-s-transferase Pi (gstp) 1 and 2 Regulate Neurite Formation in *Vitro* and in *Vivo*.

X. Liu, S. M. Blazejewski, S. A. Bennison, T. H. Smith, K. Toyooka; Drexel University College of Medicine, Philadelphia, PA.

After neurons reach the cortical plate in the developing cerebral cortex, they start polarizing and extending neurites. Neurite initiation and elongation compose the process of neurite formation. This is an important step where neurons build mature structures and form networks with each other. Gstp family proteins are enzymes involved in reductive reactions, and therefore have an essential role in detoxification. Besides the enzymatic activity, Gstp proteins are also involved in cellular signaling. Studies on Gstp have mostly focused on the enzymatic functions, such as in cancer. However, little is known for the functions of Gstp proteins in brain development. In our study, we found that mouse Gstp proteins play important roles in the neurite formation. Knockdown of mouse Gstp1 and 2 in primary cortical neurons using shRNA caused a significant decrease in neurite number at DIV2 after re-plating. Knockdown of Gstp1 and *2 in vivo* by in *utero* electroporation at E15.5 enables us to label layer 2/3 cortical neurons and analyze neurite formation in *vivo*. We found Gstp1 and 2 knockdown caused further morphological defects in *vivo* including widening of apical dendrite at P3. Live imaging showed the polarity of knockdown neurons is disrupted at P0, but this disruption is not persistent at P3. Based on our observations, we conclude that the Gstp1 and 2 are involved in neurite formation, especially the neurite initiation stage. Some interaction partners for Gstp1 and 2 have been identified, for example JNK1 and Akt, and we are intrigued to discover the molecular targets and signaling pathway responsible for the neurite formation defects seen in Gstp1 and 2 knockdown neurons.

P463/B474

***Lgl1* Is Essential for Collective Epithelial Migration by Promoting Integrin Singaling during Mammary Gland Branching.**

D. Gong, 201210[1], R. Ma[1], T. Zhou[1], C. Petritsch[2], Z. Werb[2], P. Lu[1]; [1]Shanghaitech University, Shanghai, CHINA, [2]University of California, San Francisco, CA.

Tissue polarity is a salient feature of epithelial organs and its loss is a hallmark trait of cancer, and *Lgl1* is an important protein in the epithelium to maintain tissue polarity. The use of mammary gland epithelial tissue to study the function of *Lgl1* can further reveal the regulatory mechanism and function of epithelial tissue polarity. Here, we show that *Lgl1* expression is reduced in breast cancer and its extent of reduction correlates with the severity of cancer grades. Consistent with it being a candidate tumor suppressor, *Lgl1* null cells showed higher self-renewal ability in mammosphere- and acinus-forming assays. Surprisingly, conditional removal of *Lgl1* function or transplantation resulted in stunted epithelial branching. Although *Lgl1* null cells could undergo FGF2-mediated ductal elongation, they failed in collective epithelial invasion, an essential step in vertebrate branching. To determine the molecular mechanism of failure in invasion due to loss of *Lgl1*, we discovered that ITGB1 had new interactions with Lgl1 in mice, and *Lgl1* regulates the invasion process by activating the integrin signaling pathway. Therefore, the function of tissue polarity protein Lgl1 may relate to the cellular microenvironment.

Together, our data highlights the importance of tissue polarity and actin dynamics in epithelial organ development and suggests that its loss is an essential step in solid tumor formation.

P464/B475

Linking Symmetry Breaking to Asymmetric Division in the Stomatal Lineage.

A. Muroyama[1], D. Bergmann[2]; [1]Stanford University, Stanford, CA, [2]Stanford University/HHMI, Stanford, CA.

Symmetry breaking is essential to coordinate cellular behaviors to pattern tissues in all multicellular organisms. However, our understanding of asymmetry-generating mechanisms in plants remains limited. Stomata, pores in the leaf epidermis that mediate gas exchange, are patterned by asymmetric divisions of precursor cells. In *Arabidopsis*, symmetry breaking in these cells is initiated by the polarization of BASL and BRX, plant-specific proteins that localize in a cortical crescent. This polarity domain is essential for proper division orientation and differential daughter cell fates. However, the mechanisms that link their polarization to asymmetric division remain unknown. By combining quantitative, long-term time-lapse imaging with pharmacological and genetic perturbations, we have uncovered two novel, cytoskeleton-driven pathways that link symmetry breaking to asymmetric division in plants. In one pathway, precursor asymmetry required mutual inhibition between the polarity crescent and membrane-associated microtubules. We found that anticlinal microtubules, while not required for initial polarization, restrict lateral spread of the polarity domain, conferring robustness. In turn, polarity proteins locally altered microtubule organization by suppressing microtubule stability at the membrane. Local microtubule depletion resulted in microtubule network anisotropy that is propagated through the cell cycle to position the division plane. In a parallel pathway, symmetry breaking at the membrane drives directional nuclear migration before and after division via a two-step "cytoskeletal hand-off" mechanism. We found that BASL and BRX repel the nucleus in a microtubule-dependent manner before division but attract it in an actin-dependent manner following division. This coordinated nuclear movement potentially primes consecutive asymmetric divisions to ensure that daughter cells are properly distributed throughout the leaf epidermis. Taken together, we have uncovered an evolutionarily divergent polarity system that provides a framework to understand how symmetry breaking and asymmetric cell division are coordinated in plants.

Synaptic Cell Biology

P465/B477

The G Protein-coupled Receptor Fshr-1 Regulates Neuromuscular Synapse Structure in *C. Elegans*.

M. Buckley, J. Kowalski; Butler University, Indianapolis, IN.

G protein-coupled receptors (GPCRs) are a class of transmembrane proteins involved in diverse processes across eukaryotes and are common drug targets. In the nervous system, GPCRs are receptors for numerous signaling molecules and can impact neurotransmitter release. Follicle Stimulating Hormone Receptor (FSHR) is a conserved GPCR expressed in *Caenorhabditis elegans* neurons that modulates neuromuscular signaling. In *C. elegans,* a balance of excitatory signals released from cholinergic motor neurons and inhibitory signals released by GABAergic neurons controls muscle contraction. Inhibition of *fshr-1* expression causes reduced muscle contraction and synaptic vesicle accumulation at cholinergic, and to a lesser extent, at GABAergic motor neuron presynapses, suggesting

decreased neurotransmitter release. Yet, the mechanisms by which FSHR-1 signaling impacts synaptic vesicle function are unknown. Active zone (AZ) proteins are located at presynaptic membranes and regulate synapse structure, synaptic vesicle clustering, and neurotransmitter release. As the mammalian FSHR signaling target protein kinase a can regulate the AZ protein RIM, we hypothesized FSHR-1 might regulate synaptic vesicle localization and neuromuscular signaling in *C. elegans* via effects on UNC-10/RIM or other AZ proteins. To test this, we imaged neuromuscular synapses within the dorsal nerve cords of wild type and *fshr-1* loss-of-function mutant worms expressing fluorescently tagged AZ proteins in specific motor neuron classes and quantified relative synaptic AZ protein distribution. Compared to wild type worms, *fshr-1* mutants had increased synaptic UNC-10::GFP intensity (p = 0.02) and elevated axonal fluorescence (p = 0.02) in cholinergic motor neurons, suggesting *fshr-1* is required to prevent aberrant UNC-10 accumulation at these synapses. No such differences were seen for UNC-10::Cherry in GABAergic motor neurons. To assess if the defects were specific to UNC-10, we measured the localization/abundance of other active zone proteins. *fshr-1* mutants showed slightly elevated synaptic SYD-2/Liprinα::GFP intensity (p = 0.05) and axonal fluorescence (p= 0.04) in cholinergic neurons, following a similar but less robust trend than seen with UNC-10::GFP. *fshr-1* mutants expressing CLA-1/Clarinet::GFP showed no significant differences from wild type worms in cholinergic neurons. Together these data suggest that FSHR-1 may regulate neuronal communication and synaptic vesicle release through effects on UNC-10 and SYD-2. Future studies will examine the mechanisms by which FSHR-1 controls synaptic UNC-10 and SYD-2 levels. Given the conservation of *C. elegans* and human genes/nervous system organization, elucidating FSHR-1 biology may aid knowledge of human neurological disorders.

P466/B478

Exploring the Fshr-1 Gpcr Signaling Pathway in Controlling *C. Elegans* Neuromuscular Signaling.

A. Shores, D. Ryskamp, S. Oloffson, A. Munneke, A. Godfrey, J. Kowalski; Butler University, Indianapolis, IN.

A tightly regulated balance of excitatory and inhibitory (E:I) neuronal signals is essential for nervous system function; E:I imbalances occur in many neurological diseases. G-protein coupled receptors (GPCRs), which activate multi-protein pathways in diverse cell types in response to diverse signals, are important regulators of this balance. Given the high number of GPCRs and downstream components, the function and members of many GPCR pathways in specific cell types are unknown. This is particularly true in the nervous system, where GPCRs can serve as receptors for molecules including neurotransmitters and neuropeptides. FSHR is a mammalian GPCR that regulates reproductive physiology via its expression in the gonad; however, FSHR is also expressed in nervous tissue, where its function is unknown. The *C. elegans* homolog FSHR-1 is also expressed in neurons where it controls E:I balance at the neuromuscular junction (NMJ) in these roundworms. At the *C. elegans* NMJ, excitatory acetylcholine (Ach) signaling and inhibitory γ-aminobutyric acid (GABA) signaling control muscle contraction. The specific targets of FSHR-1 at the NMJ and its downstream pathway components in this context have not yet been elucidated. In the *C. elegans* germline, FSHR-1 acts upstream of the Gαs protein GSA-1 and the adenylyl cyclase ACY-1, and a GSA-1—ACY-1—PKA pathway controls synaptic vesicle release in motor neurons. We investigated whether FSHR-1 activates this pathway to affect muscle contraction. Our preliminary data suggest FSHR-1 can act in multiple cell types, including Ach and GABA motor neurons, to control muscle excitation via effects on synaptic vesicle release; however, experiments testing the potential FSHR-1 pathway indicated that, while FSHR-1 acts upstream of GSA-1

at the NMJ, ACY-1 and PKA may not function downstream of FSHR-1 in one or more of these cell types. Three family members of ACY-1 – ACY-2, -3 and -4 – are structurally similar to ACY-1, and expression of genes encoding several of these proteins has been reported in neurons. Thus, we hypothesize that ACY-2, -3, and/or -4 may act downstream of FSHR-1 and upstream of PKA in one or more NMJ cell types. Using RNA interference and aldicarb paralysis assays, we found a requirement for *acy-3* in GABA neurons, as well as confirmed a requirement for genes encoding *unc-2* (CACNA1B), *unc-10* (RIM1), and *egl-36* (KCNC1, 2 and 4) for normal muscle contraction at the *C. elegans* NMJ. Current experiments are assessing these genes and PKA for roles downstream of FSHR-1 and will examine the potential activation of this pathway by neuropeptide- and FSH-related genes. Given the similarity between worm and human genes and nervous systems, this research provides insight into the molecular mechanisms by which GPCRs like FSHR-1 control neuronal signaling.

P467/B479

Neto-mediated Intracellular Interactions Sculpt Postsynaptic Composition at the *Drosophila* Neuromuscular Junction.

S. D. Choudhury, L. Friend, M. Serpe; NIH/NICHD, Bethesda, MD.

Recruitment of neurotransmitter receptors and organization of postsynaptic densities (PSDs) are crucial for the formation of neural circuits and for the long-term plasticity underlying learning and memory. *Drosophila* neuromuscular junction (NMJ), a glutamatergic synapse similar to our central synapse, is a powerful genetic system to study synapse assembly and function. We have previously found that trafficking and stabilization of the ionotropic glutamate receptor (iGluRs) at the *Drosophila* NMJ requires Neto, a highly conserved auxiliary protein. Neto binds to iGluRs and modulates their function, but also engages in intracellular and extracellular interactions that shape PSD composition and enable iGluRs stabilization at synaptic sites. *Drosophila neto* codes for two isoforms, Neto-alpha and Neto-beta, which have distinct cytoplasmic domains generated by alternative splicing. Neto-beta, the predominant isoform at the larval NMJ, is key to the recruitment of iGluRs and PSD components such as p21-activated kinase (PAK), a PSD component known to selectively stabilize type a glutamate receptors. Here we propose that the cytoplasmic domain of Neto-beta provides a signaling platform required for PSD assembly and function. To test this hypothesis, here we have used CRISPR/Cas-9 and generated a series of *neto-beta* alleles with progressively truncated intracellular domains, or with small internal deletions. The 351-residue intracellular part of Neto-beta contains multiple putative phosphorylation sites and docking motifs, including an SH3 binding motif and a putative CaMKII phosphorylation site. Loss of the entire Neto-beta intracellular domain or truncations which remove the SH3 binding and the CaMKII putative phosphorylation site abolished the synaptic recruitment of dPix, a Rho-type guanine nucleotide exchange factor required for synaptic recruitment of PAK, and thus stabilization of type a glutamate receptors at the PSD. Interestingly, dPix recruitment was also disrupted by a small, 11 residue deletion which removes the putative CaMKII phosphorylation site. We will discuss the unexpected phenotype of this small deletion and the role of this Neto-beta motif on PSD assembly and NMJ functionality. Our study demonstrates that Neto functions as a critical PSD scaffold and a hub for cellular signaling at glutamatergic synapses.

P468/B480

Neto-α Controls Synapse Organization and Homeostasis at The*Drosophila*NMJ.

R. Vicidomini[1], T. Han[1], C. Ramos[2], M. Serpe[1]; [1]NIH/NCHID, Bethesda, MD, [2]University of Lyon, Lyon, FRANCE.

Formation of functional synapses during development, and their fine-tuning during plasticity relies on ion channels and their accessory proteins. Auxiliary proteins are transmembrane proteins which associate with channel complexes and mediate their properties and distribution. Neto proteins are highly conserved auxiliary subunits which modulate the kainate-type glutamate receptors (KARs). In mammals, Neto/KAR complexes are critical for synapse plasticity but the underlining mechanism are extremely difficult to study due to the low abundance of these channels and the small currents they elicit. In contrast, Drosophila utilizes Neto and KARs at the NMJ, a synapse essential for viability. We demonstrated that Neto is required for synapse assembly and function at fly NMJ: in the absence of Neto, the NMJ iGluRs fail to cluster at the nascent synapses and the mutant animals die as paralyzed embryos. Here we show that Neto evolved functionally distinct isoform to modulate synapse development and homeostasis. *Drosophila neto* encodes two isoforms, α and -β, which share the extracellular and transmembrane parts but have distinct intracellular domain. Loss of Neto-β, the predominant isoform at the fly NMJ, drastically reduces the levels of post-synaptic receptors; however, these mutants have normal evoked potentials due to a robust compensatory increase of neurotransmitter release. Neto-α represents less than 10% of the total Neto at the NMJ and *neto-α^{null}* mutants have reduced evoked potentials and lack the ability to compensate for chronic or acute reduction of iGluRs activity. Interestingly, these mutants retain the ability to attenuate the excitatory effects of excess glutamate release. Our studies indicate that Neto-α functions in both pre- and post-synaptic compartments. In muscle, Neto-α limits the size of the postsynaptic receptors field. In motor neurons, Neto-α controls basal neurotransmission in a KAR-dependent manner. Furthermore, Neto-α is both required and sufficient for the presynaptic increase in neurotransmitter release in response to reduced postsynaptic sensitivity. This KAR-independent function of Neto-α is involved in activity-induced cytomatrix remodeling. Neuronal expression of Neto-β cannot rescue the defects of *neto-α^{null}* because Neto-β cannot traffic to the synaptic terminals. In contrast, a Neto variant with no intracellular domains (dCTD) can reach the presynaptic terminal, can rescue the basal neurotransmission defects of *neto-α^{null}*, but cannot restore their homeostatic response. Our studies indicate that the intracellular part of of Neto-α functions as a bona fide effector of synapse homeostasis. We propose that *Drosophila* ensured NMJ functionality by acquiring two Neto isoforms with different expression patterns and activities.

P469/B481

Ayahuasca Increases the Expression of Glur1 and Glur2/3 Ampa Receptors in the Hippocampus and Induces Opposite Changes in the Prefrontal Cortex of Wistar Rats.

G. Rocha[1], R. B. Bertequini[1], V. P. Gervásio[1], G. S. Calfi[1], M. M. Iyomasa-Pilon[2], S. C. H. Regalo[3], S. Siéssere[3], J. E. C. Hallak[4], **M. L. M. Rosa**[1,5]; [1]Barretos School of Health Sciences Dr. Paulo Prata, FACISB, Barretos, BRAZIL, [2]School of Medicine of Catanduva, FIPA, Catanduva, BRAZIL, [3]Department of Histology, School of Dentistry of Ribeirao Preto-USP, Ribeirao Preto, BRAZIL, [4]Department of Neurosciences and Behavioral Sciences, School of Medicine of Ribeirão Preto-USP, Ribeirao Preto, BRAZIL, [5]Institute of Neuroscience and Behavior, INeC-USP, Ribeirao Preto, BRAZIL.

The consumption of Ayahuasca beverage is usual in several Brazilian syncretic religions that have expanded to Europe and North America. It is made from an Amazonian psychoactive plant containing the serotonin agonist N,N-dimethyltryptamine and the monoamine oxidase-inhibiting alkaloids (harmine, harmaline and tetrahydroharmine), resulting in enhanced serotonergic activation. Ayahuasca has also been reported to affect glutamatergic processes in brain areas including prefrontal cortex (PFC) and hippocampus, which play important roles in the neuropsychiatric disorders. This work aimed at investigating whether the ingestion of Ayahuasca might induce alterations in the expression of glutamate AMPA receptors (GluR1 and GluR2/3) in the hippocampus and dorsolateral PFC of rats. Six groups of male Wistar rats (230-250g, n=5-8/each) received 0.2 or 0.4ml/g of Ayauhasca, only once (acute), 3 times/day/3 days (subchronic) or once/day/15 days (chronic). Six control groups received water at the same conditions. After the last ingestion the animals were anaesthetized, perfused and their brains sectioned (40μm) for immunohistochemistry. The number of immunopositive cells (IC) was quantified, bilaterally, in the hilus of dentate gyrus (HDG), CA3, CA1 and in the superficial and deep layers of the PFC. Comparisons used ANOVA followed by Bonferroni, DMS and Duncan tests ($p \leq 0.05$). The acute ingestion of Ayahuasca (0.2ml/g) induced a decrease in GluR1 IC in CA1 (18%), while 0.4ml/g (acute or chronic) induced an increase in the HDG (30% and 29%) and CA1 (10% and 23%), respectively. Subchronic treatment showed no difference. For GluR2/3 IC, only chronic ingestion of either 0.2ml/g or 0.4ml/g of Ayahuasca induced an increase in CA3 (25%) and CA1 (20%). Acute, subchronic or chronic ingestion of 0.2 or 0.4ml/g of Ayahuasca induced an increase in GluR1 IC in both superficial and deep layers of the PFC (6-21%, $p<0.01$). However, for GluR2/3 IC, acute and subchronic treatments induced a decrease (7-15%, $p<0.01$) in both layers, while only the chronic ingestion of 0.2ml/g induced an increase (17-23%, $p<0.01$). No difference was found after chronic ingestion of 0.4ml/g. When the Ayahuasca groups were compared, the ingestion of 0.4ml/g always induced lower expression in both GluR1 and GluR2/3 than 0.2ml/g (7-18%, $p<0.001$). Acute or chronic ingestion of Ayahuasca may trigger distinct mechanisms in the hippocampus and PFC involving the modulation of glutamate through the activation of serotonin. Considering the involvement of both areas in several neurodegenerative and psychiatric disorders, glutamate might be a potential therapeutic target for the treatment of disorders where the glutamatergic dysfunction is associated with the serotonergic system activation. Selective Disruption of Bmp Signaling by a Smad Mutation Adjacent to the Highly Conserved H2 Helix.

T. HUU NGUYEN, T. Hee Han, M. Serpe; NIH, Bethesda, MD.

Bone morphogenetic protein (BMPs) modulate a wide variety of cellular processes via canonical and non-canonical signaling pathways. BMP signaling is initiated by ligands binding to type I and type II BMP receptors, and transduced by BMP effectors, Smads (Mad in *Drosophila*), which upon phosphorylation translocate in the nucleus and modulate gene expression. In flies, a canonical BMP pathway regulates neuromuscular junction (NMJ) growth and function. We have recently described a genetically distinct BMP signaling modality characterized by accumulation of phosphorylated Mad (pMad) at synaptic sites. This local BMP signaling functions as a sensor of synapse activity: it monitors active type-A postsynaptic glutamate receptors and acts locally to promote the stabilization of these receptors at synaptic terminals. To learn more about molecular features of Mad and understand how pMad could remain associated with its own (BMP receptor) kinase, we searched through available *Mad* alleles for mutants which differentially disrupt the two BMP signaling pathways. Within this comprehensive collection, we

found that strong *Mad* alleles generally disrupt both synaptic and nuclear pMad accumulation, whereas moderate *Mad* alleles have a wider range of phenotypes and selectively impact different BMP signaling modalities. In particular, Mad^{8}, which contains a single point mutation, S359L, showed drastically reduced synaptic pMad levels but mildly diminished nuclear pMad signals. The postsynaptic composition and electrophysiological properties of Mad^{8} NMJs were likewise altered. Using a cell-based assay, we found that pMad, but not pMad8, readily associates with activated BMP type I receptors at the cell membrane. Furthermore, structural modeling suggests that a highly conserved motif adjacent to S359, the H2 helix, is a critical determinant for the Smad-Type I receptor interaction. Several genetic variants identified in human patients map to H2, underscoring the relevance of this motif for normal development and function. This study demonstrates that the H2 helix is a class specific molecular determinant for local BMP signaling and suggests that mutations in this region disrupt specialized tight junctions throughout the animal kingdom.

Cytoskeletal Remodeling Regulates Human Fetal Synaptogenesis.

T. Rudisill, B. Kirk, K. Tate, E. Wilson, P. Kemper, S. Goertzen, **K. Litwa, Ph.D.**; East Carolina University, Greenville, NC.

Excitatory synapse formation occurs during mid-fetal gestation. However, due to our inability to image fetal synaptogenesis, the pre-natal period remains understudied. The recent development of human brain spheroids provides access to this critical period. Using human neurons and brain spheroids, we address how altered actin regulation impacts the formation of excitatory synapses during fetal brain development. We demonstrate that inhibition of RhoA kinase (ROCK) signaling promotes neurite formation and elongation. In addition to increasing neural complexity, ROCK inhibition increases spine precursor length. These increases correspond with increased excitatory synapse formation in human brain spheroids. Rac-driven actin polymerization drives this increase in excitatory synaptogenesis, and supports spontaneous action potential formation. Using STORM super-resolution microscopy, we localize key upstream RhoGTPase regulators (GEFs, GAPs) to nascent excitatory synapses, providing evidence for differential actin regulation at pre- and pos-synaptic compartments of emerging synapses. These results demonstrate that coordinated RhoGTPase activities underlie fetal excitatory synaptogenesis, and identify critical regulators of early synaptogenic events.

Presynapse Active Zones Assemble through Phase Separation of Scaffolding Molecules.

N. McDonald, K. Shen; Stanford University, Stanford, CA.

The presynaptic active zone is the site of release of vesicles containing neurotransmitters. Components of the active zone are responsible for tethering and priming synaptic vesicles, recruiting and clustering ion channels to respond to action potentials, and structurally stabilizing the synapse through transmembrane connections to the postsynaptic cell. Decades of study have revealed the protein components of active zones, as well as a number of protein-protein interactions between them. Yet how these components assemble into functional active zones down a distant axon is not clear. Here, we show that two widely conserved active zone components in C. elegans, SYD-2/Liprin-α and ELKS-1, undergo a liquid-liquid phase separation to assemble the active zone. To probe active zone protein behavior in *vivo*, we measured protein mobility in newly formed *C. elegans* synapses. We found that

young active zones are dynamic and recover quickly after photobleaching, consistent with a possible phase separation. In contrast, established active zones are highly static with nearly zero cytoplasmic exchange. We find that SYD-2/Liprin-α and ELKS-1, two core active zone scaffolding proteins, are capable of liquid-liquid phase separation in *vitro* and rely upon multiple unstructured motifs for this activity. By selectively deleting short regions in these motifs, we specifically blocked phase separation activity without affecting other known functions of the proteins. When introduced endogenously in *vivo*, these mutations inhibit the early dynamics of developing synapses, supporting a phase separation during normal active zone assembly. We find that SYD-2/Liprin-α phase separation-blocking mutants localize normally to synapses; however, by imaging synapses of the Hermaphrodite Specific Neuron (HSN), we find additional active zone components fail to localize properly and synaptic vesicles fail to appropriately cluster. These defects in HSN active zone assembly lead to defects in its functional output of egg-laying, underscoring the importance of a phase separation in building the presynaptic active zone. Together these data show presynaptic active zones are assembled through a phase separation of core scaffold molecules. This mechanism may aid in tightly concentrating scaffolding proteins at nascent synapses, forming a potent sink to recruit binding partners and downstream active zone components.

Mitochondrial Calcium Store and Downstream NAD(H) Redox Homeostasis Modulates Hair-cell Presynapse Size during Synapse Formation.

H. C. Wong, Q. Zhang, A. Beirl, K. Kindt; NIDCD/NIH, Bethesda, MD.

Mechanosensitive hair cells of the inner ear and lateral line relay sensory information to the brain for vital behaviors such as hearing, balance and predator avoidance. Hair cells are epithelial cells that can transmit sensory information with specialized synapses, which have membraneless, proteinaceous “ribbons” anchored at the presynaptic active zone. Recent studies have shown that ribbon size can directly regulate the properties of this synapse. The main component of the ribbon is the protein Ribeye, which contains a NAD(H) binding domain shown to alter Ribeye self-aggregation in vitro. Our study aims to understand if cellular NAD(H) redox can impact Ribeye self-aggregation and ribbon formation determination in vivo. To study hair cell presynapse formation in vivo, we use transgenic larval zebrafish expressing fluorescent calcium biosensors and NAD(H) redox indicators in hair cells to visualize calcium dynamics and the NAD^+/NADH ratio. Our work also uses pharmacology to disrupt hair cell calcium and NAD(H) redox homeostasis. To quantify ribbon morphology we image immunofluorescence staining of Ribeye using Airyscan confocal microscopy. In developing hair cells, we found that application of exogenous NAD^+ or NADH increased or decreased the NAD^+/NADH ratio in hair cells. Furthermore, NAD^+ or NADH increased and decreased ribbon formation respectively. Additionally we found that in developing hair cells, spontaneous presynaptic and mitochondrial calcium uptake control the NAD^+/NADH ratio; these calcium signals also strongly affect ribbon formation. These results suggest that spontaneous presynaptic and mitochondrial calcium uptake modulate ribbon formation through depressing NAD^+/NADH ratio. This change in NAD^+/NADH ratio indicates that in hair cells, spontaneous activity may alter cellular metabolism to control development. Overall, these results propose a physiological mechanism that allows calcium influx and NAD(H) redox to regulate presynapse morphology.

P474/B486

Glyoxal, a Potent Substitute for Paraformaldehyde/glutaraldehyde Fixation in Modern Electron Microscopy.

J. Quiñones-Rodriguez, T. Schikorski; Universidad Central del Caribe, Bayamon, PUERTO RICO.

Chemical fixation is one of the most critical steps to retain cellular structure and histochemical integrity. Recent advances with glyoxal as a fast fixative resulted in better structural preservation and better antigenicity in light microscopy and super-resolution microscopy. Those studies reported an increase in labeling intensity in immunolabelling of up to 100%. The penetration depth of antibodies was also substantially improved. Here, we present the very first data of modern glyoxal fixation applied to electron microscopy. We used primary hippocampal cell culture as our model and compared glyoxal fixation with established fixation techniques for electron microscopy. After classical fixation with glyoxal, we found similar improvements in labeling intensity with antibodies as reported for super-resolution. We used immunogold localization of synaptic vesicle proteins to quantify labeling intensity (gold particle per synaptic vesicle). When we used modern glyoxal fixation in which acids have been removed from commercial glyoxal, the fine structure was excellently preserved and was comparable if not better compared with established electron microscopic procedures.

Molecular Tuning of the Axonal Mitochondrial Ca^{2+} Uniporter Ensures Metabolic Flexibility of Neurotransmission.

G. Ashrafi[1], J. de Juan-Sanz[2], R. J. Farrell[1], T. A. Ryan[1]; [1]Weill Cornell Medical College, New York, NY, [2]Sorbonne Universités and Institut du Cerveau et de la Moelle Epinière (ICM) - Hôpital Pitié-Salpêtrière, Inserm, CNRS, Paris, FRANCE.

The brain is a vulnerable metabolic organ and must adapt to different fuel conditions to sustain cognitive function. Activity drives local ATP production in nerve terminals through activation of glycolysis and oxidative phosphorylation. Nerve terminals are a locus of metabolic vulnerability but how they regulate ATP synthesis as fuel conditions vary is unknown. We previously demonstrated that when glucose is present, glycolysis is stimulated in firing nerve terminals through recruitment of the glucose transporter GLUT4 to presynaptic membrane. Here, we show that synapses can switch from glycolytic to oxidative metabolism, but to do so, they rely on activity-driven presynaptic mitochondrial Ca^{2+} uptake to accelerate ATP production. The mitochondrial Ca^{2+} uniporter (MCU) which mediates Ca^{2+} uptake is reported to have a low affinity for Ca^{2+} in non-neuronal cells and relies on Ca^{2+} release from ER to open. We demonstrate that unlike non-neuronal cells, presynaptic mitochondria do not rely on the ER as a source of Ca^{2+} during uptake. In fact, axonal mitochondria readily take up Ca^{2+} in response to small changes in cytosolic Ca^{2+}, while in non-neuronal cells, mitochondrial Ca^{2+} uptake requires elevated extramitochondrial Ca^{2+}. We identified the brain-specific regulator of the MCU, MICU3, as a critical driver of this tuning of Ca^{2+} sensitivity. Knockdown of MICU3 lowers the Ca^{2+} sensitivity of axonal mitochondria similar to non-neuronal mitochondria, prevents acceleration of local ATP synthesis, and impairs presynaptic function under oxidative conditions. Conversely, overexpression of MICU3 in non-neuronal cells significantly lowers the threshold for mitochondrial Ca^{2+} uptake, suggesting that MICU3 is both sufficient and necessary for regulating the Ca^{2+} sensitivity of presynaptic mitochondrial Ca^{2+} uptake. Thus, presynaptic mitochondria rely on MICU3-driven mitochondrial Ca^{2+} uptake during activity to accelerate ATP production and achieve metabolic flexibility. The mechanisms underlying the metabolic

plasticity of mammalian brain serve to ensure that cognitive performance is faithfully maintained in the face of changing nutrient availability.

Demonstrating Synaptic Vesicle Recycling *Via* Clathrin Coated Vesicles in Mammalian Neuromuscular Junctions and Central Synapses.

J. E. Heuser, T. I. Tenkova; Section on Integrative Biophysics, National Institute of Child Health & Human Development, National Institutes of Health, Bethesda, MD.

The concept that synaptic vesicles are the neuronal organelles that mediate quantal secretion of neurotransmitter has been accepted for decades now, and has been "proven" by a wide range of electron microscopical techniques. However, still under investigation are various critical aspects of how exactly synaptic vesicles are formed in the first place, and what happens to them after they discharge their transmitter quanta. Still, it is not possible to "stop-frame" the activity of an intact in *situ* neuronal net, and then to recognize and characterize all the various stages in synaptic vesicle formation, discharge, and recycling that must occur in healthy synapses. To finally accomplish this goal, we here return to the very start of this field of research, when we first introduced the concept of synaptic vesicle recycling by showing that the trivalent cation lanthanum (La+++) tremendously stimulated spontaneous transmitter release at the frog neuro-muscular junction (NMJ), and thereby exaggerated all the vesicle-transformations that are associated with neurotransmitter release. To accomplish this again here, we introduce a new mammalian neuromuscular preparation that is ideal for studying this process in the electron microscope - the intrinsic muscle of the mouse's ear - and we use this new preparation to show that La+++ mobilizes vesicle recycling in the 'cleanest' possible way, without causing any collateral damage to the synapse. We then carry this technique into CNS synapses, using tissue-cultures of mouse hippocampal neurons, to show that La+++ stimulates synaptic vesicle recycling in central synapses just as it does at the NMJ, and works in the same way, and with the same consequences - namely, *via* the turnover of synaptic vesicles mediated by clathrin-coated vesicle formation from the presynaptic membrane, after vesicle discharge. These new observations further establish our original proposal for how synaptic vesicles recycle as the proper modus operandi for future work aimed toward deeper understanding of the molecular basis of synaptic transmission.

P477/B489

Ultrafast Synaptic Vesicle Dynamics during Neurotransmitter Release.

G. F. Kusick; Johns Hopkins University, School of Medicine, Baltimore, MD.

Synaptic vesicles fuse with the plasma membrane to release neurotransmitter following an action potential, after which new vesicles must refill vacated release sites. How many vesicles can fuse at a single active zone, where they fuse within the active zone, and how quickly they are replaced with new vesicles is not well-established. To capture synaptic vesicle exocytosis at cultured mouse hippocampal synapses, we induced single action potentials by electrical field stimulation then subjected neurons to high-pressure freezing to examine their morphology by electron microscopy. During synchronous release, multiple vesicles can fuse at a single active zone; this multivesicular release is augmented by increasing the extracellular calcium concentration. Synchronous fusions are distributed throughout the active zone, whereas asynchronous fusions are biased toward the center of the active zone. Immediately after stimulation a large fraction of plasma membrane-attached (docked) vesicles are lost,

both due to fusion and undocking. Between8 and 14 ms, new vesicles are recruited to the plasma membrane and fully replenish the docked pool, but docking of these vesicles is transient and they either undock or fuse within 100 ms. These results demonstrate that recruitment of synaptic vesicles to release sites is rapid and reversible.

A Specific Splice Isoform of Dynamin-1 Mediates Ultrafast Endocytosis.

Y. Imoto[1], P. Fenske[2], S. Raychaudhuri[1], T. Trimbuch[2], C. Rosenmund[2], S. Watanabe[1,3]; [1]Department of Cell Biology, Johns Hopkins University, School of Medicine, Baltimore, MD, [2]Institute of Neurophysiology, Charité Universitätsmedizin Berlin, Berlin, GERMANY, [3]Solomon H. Snyder Department of Neuroscience, Johns Hopkins University, School of Medicine, Baltimore, MD.

Membrane remodeling is a basic property of eukaryotic cells which generates a variety of structures, such as vesicles from the plasma membrane or daughter organelles from preexisting organelles. Following membrane invagination, GTPase dynamin family member proteins mediate fission of internalized structures. The timescale of dynamin-mediated membrane scission is thought to be at least 5-10 seconds. However, recently identified ultrafast endocytosis occurs in less than 100 ms during synaptic vesicle recycling in hippocampal neurons. Thus, the molecular mechanism underlying the rapid cleaving of this endocytic pit from the plasma membrane is not known. To reveal molecular underpinnings of this process, we coupled genetic depletion with flash-and-freeze microscopy, which visualizes membrane dynamics of synapses in electron micrographs with millisecond temporal resolution. Our data show that a specific splice variant of GTPase Dynamin-1 is required at the plasma membrane to retrieve endocytic vesicles within 100 ms after synaptic vesicle fusion. Dynamin 1 is recruited to the endocytic pit by Syndapin 1, an F-BAR protein which functions during the early stage of membrane invagination. Further, the kinetics of constriction require the interaction of Dynamin 1 and Syndapin 1. During Dynamin 1-dependent rapid membrane scission, Endophilin is also needed to stabilize and constrict steep negative curvature at the base of the endocytic pit. Thus, despite its intrinsic speed, it is the coordinated action of dynamin and its interacting partners which regulate rapid membrane cleaving during ultrafast endocytosis.

Maturation and Clearance of Autophagosomes in Neurons Depends on a Specific Cysteine Protease Isoform, Atg-4.2.

S. E. Hill[1,2], K. J. Kauffman[2], M. Krout[3], J. E. Richmond[3], T. J. Melia[2], D. A. Colon-Ramos[1,2,4]; [1]Department of Neuroscience, Program in Cellular Neuroscience, Neurodegeneration and Repair, Yale University School of Medicine, New Haven, CT, [2]Department of Cell Biology, Yale University School of Medicine, New Haven, CT, [3]Department of Biological Sciences, University of Illinois at Chicago, Chicago, IL, [4]Instituto de Neurobiología, Recinto de Ciencias Médicas, Universidad de Puerto Rico, San Juan, PUERTO RICO.

In neurons, defects in autophagosome clearance have been associated with neurodegenerative disease. Yet, the mechanisms that coordinate trafficking and clearance of synaptic autophagosomes are poorly understood. Here, we use genetic screens and in *vivo* imaging in single neurons of *C. elegans* to identify mechanisms necessary for clearance of synaptic autophagosomes. We observed that autophagy at the synapse can be modulated in *vivo* by the state of neuronal activity, that autophagosomes undergo UNC-

16/JIP3-mediated retrograde transport, and that autophagosomes containing synaptic material mature in the cell body. Through forward genetic screens, we then determined that autophagosome maturation in the cell body depends on the protease ATG-4.2, but not the related ATG-4.1, and that ATG-4.2 can cleave LGG-1/Atg8/GABARAP from membranes. Our studies revealed that ATG-4.2 is specifically necessary for the maturation and clearance of autophagosomes and that defects in transport and ATG-4.2-mediated maturation genetically interact to enhance abnormal accumulation of autophagosomes in neurons

P480/B492

RNA-sequencing Identifies Altered Gene Expression in the Ventromedial Hypothalamus Following Acute Predator Odor Exposure.

A. S. Barnard, M. Gibson, C. Novak; Kent State University, Kent, OH.

Energy expended during activity is the second largest contributor to our total daily energy expenditure (EE). Uncovering ways to increase EE during activity could yield new treatments for obesity. The ventromedial medial hypothalamus (VMH) regulates body weight by modulating peripheral metabolism and sympathetic nervous system (SNS) activity. Interestingly, the VMH is a critical mediator of behavioral responses to predator threat. Previously, we've shown that predator odor (PO) exposure to rats causes a rapid and robust increase in skeletal muscle thermogenesis and EE even when controlling for physical activity and is associated with weight loss. VMH cells are a likely mediator of these PO-induced metabolic responses, but the causal links remain unexplored. To probe potential targets, we performed RNA-sequencing on RNA isolated from the VMH of rats exposed to a piece of towel (2" x 1.5") previously housed with ferrets or a clean piece of towel in their homecage. After 20 min of exposure, rats were anesthetized with isoflurane and rapidly decapitated. Brains were flash frozen in isopentane on dry ice. RNA was isolated from VMH micropunches using a combination of Trizol and columns. Samples were sent to Novogene for RNA-sequencing and analysis. An alysis using DESeq software identified 164 differential expressed genes (DEGs). A gene ontology (GO) enrichment analysis revealed 65 enriched GO terms. Kyoto encyclopedia of genes and genomes (KEGG) analysis indicated enrichment of 28 pathways. Taken together, our results showed common themes of immune response, oxidative stress, alterations in inter-cell communication and neuronal morphogenesis and plasticity. Cross-examining our findings with previous literature revealed an interesting pattern wherein many of our DEGs and enriched pathways have independently been implicated in brain regulation of metabolism and/or response to predator threat, but rarely have these DEGs been functionally connected in these contexts. We are the first to explore transcriptome-wide alterations of the VMH following PO exposure. Our results have uncovered novel functional relationships among genes that can now be probed to better understand the dual processing role of the VMH in metabolism and predator threat responses.

P481/B493

Interplay between Nmda and Ampa Type Glutamate Receptors May Facilitate Learning in Caenorhabditis Elegans.

B. Henderson, W. Faruqi, D. Hassel, J. Rose, L. Dahlberg; Western Washington University, Bellingham, WA.

In order for nerve cells to communicate with each other, they must use receptor proteins to send chemical and electrical signals. One class of receptor proteins that are central to learning and memory in

mammals are the glutamate receptors. Changes in protein and mRNA levels of glutamate receptors underlie the neurobiology of learning and memory. Glutamate receptors are also found in the model organism, *C. elegans*. In *C. elegans*, NMDA and AMPA type glutamate receptors, called NMR-1 and GLR-1 respectively, are involved in learning as well as movement. In order to understand how NMR-1 and GLR-1 cooperate in associative learning, we tested how behavior and biochemistry are affected when animals with the presence and absence of *nmr-1* are challenged to associate a stimulus with a tone. In order to assess changes in *C. elegans* during associative learning, animals were synchronized by age, then trained by subjecting them to two aversive stimuli: a vibrational and blue light stimulus. Behavioral testing revealed that after training, animals have a statistically significant change in behavioral response in wildtype and *nmr-1* worms. We also measured how GLR-1 tagged with GFP (GLR-1::GFP) changed in worms with a deletion in the *nmr-1* gene. We measured GLR-1::GFP protein abundance with western blotting and mRNA levels with qPCR (TaqMan) assays.A large increase in GLR-1::GFP mRNA, but a decrease in GLR-1::GFP protein, was seen in wild type worms after training. However, naïve and trained *nmr-1* mutants only showed a decrease in GLR-1::GFP protein abundance. These findings suggest there may be other proteins or compensatory mechanisms involved in regulating GLR-1 in both scenarios. Additional experiments are being carried out on all strains by collecting worms immediately after and 24hr after being trained establish whether the discrepancy between mRNA and protein levels is a time dependent event.

P482/B494

Cocaine-induced Functional Deficit in Orbitofrontal Cortex Is Prevented by Systemic Administration of a Sigma-1 Receptor an tagonist.

Y. Kimura[1], M. J. Sharpe[2], A. Zapata[1], A. Wright[1], L. E. Mueller[1], C. Lupica[1], G. Schoenbaum[1], T. Su[1]; [1]National Institutes of Health / National Institute on Drug Abuse, Baltimore, MD, [2]University of California, Los an geles, Los an geles, CA.

The orbitofrontal cortex (OFC) is necessary for inferring expected outcomes to guide appropriate responding. This function can be shown in a sensory preconditioning task, in which behavior to the preconditioned but not the directly conditioned cue is sensitive to inactivation of the OFC after learning. Self-administration of cocaine causes similar deficits in preconditioning, suggesting drug-induced problems in model-based inference that might complicate treatment.The sigma-1 receptor (Sig-1R) is a chaperone protein predominantly expressed on the ER membrane. It has been reported that the receptor modulates the function of other proteins by physical interaction. Many synthetic compounds, including psychiatric drugs and psychostimulants bind to the Sig-1R, and cocaine is known to act as an agonist. We previously reported that a Sig-1R antagonist, BD1063, given prior to administration of cocaine, attenuated behavioral sensitization caused by cocaine, and reversed the cocaine-induced hypoexcitability of medium spiny neurons in nucleus accumbens. Here, we investigated the potential role of Sig-1R in cocaine-induced functional alterations of OFC. Sig-1Rs were localized in the rat OFC by immunohistochemistry and western blot. Rats were given the opportunity to spontaneously acquire self-administration of cocaine or sucrose, with a prior injection of either BD1063 or saline for 12 days. After four weeks of cocaine withdrawal, rats were trained in a sensory preconditioning task. As reported previously, rats withdrawn from cocaine self-administration exhibited a deficit in sensory preconditioning performance, failing to respond appropriately to the preconditioned cue. This deficit was not present in rats that had received the Sig-1R antagonist BD1063 prior to each cocaine self-administration session. The potential mechanisms underlying this result were further examined.

Unexpectedly, the electrophysiological activity of the serotonin 2A receptor (5HT-2AR) in the OFC of different treatment groups did not differ. An other potential target, the gamma-aminobutyric acid receptor (GABAR) which can interact with Sig-1R as seen per immunoprecipitation in HEK cells is now being investigated. Further, a relatively new tag, APEX2, combined with mass spectrometry analyses, is being used to reveal the sub-global profile of molecular changes among the groups. Although more experiments are needed including the use of Sig-1R antagonist during cocaine withdrawal, our data suggest the Sig-1R as a potential therapeutic target in the treatment of cocaine addiction. (This study supported by IRP/NIDA/NIH/DHHS)

Galectin-8, Target of Autoantibodies, Binds Alpha-amino-3-hydroxy-5-methyl-4-isoxazolepropionic Acid Receptor (AMPAR) and Enhances Its Trafficking to the Cell Surface, Post-synaptic Transmission and Plasticity Involved in Spatial Memory.

F. Barake[1,2], C. Oliva[1], S. Espinoza[1,2], F. Carvajal[1,3], L. Hernandez[2], E. Pardo[1], C. Retamal[2], N. Leal[1], A. de la Peña[2], B. Vasquez[1,2], C. Oyanadel[2], W. Cerpa[1,3], A. Álvarez[1], A. Soza[1,2], N. C. Inestrosa[1,3], A. Gonzalez[1,2]; [1]Pontificia Universidad Católica Chile, Santiago, CHILE, [2]Universidad San Sebastián, Santiago, CHILE, [3]Universidad de Magallanes, Punta Arenas, CHILE.

Galectin-8 (Gal-8) interacts with beta-galactosides moieties of selective cell surface glycoproteins including signaling receptors and integrins, with preference for alpha-2,3 sialic acids. In the brain, we have shown that Gal-8 has immunosuppressive and neuroprotective roles, being expressed in several brain regions, including hippocampus and the choroid plexus. Gal-8 is also present in cerebro-spinal fluid. Autoantibodies from patients with autoimmune diseases such as systemic lupus erythematosus (SLE) and multiple sclerosis can block Gal-8 functions. As these autoantibodies have been detected in the brain, it is important to understand the role of Gal-8 in neurons. We first performed a proteomic analysis of interactors, which pointed to AMPAR among other synaptic proteins. Pull-down and co-immunoprecipitation experiments confirmed Gal-8/AMPAR interaction involving alpha-2,3 sialic acids. AMPAR endocytic recycling is highly regulated and crucial in synaptic plasticity and memory processes. Surface biotinylation revealed that neurons in primary culture respond to Gal-8 by rapidly (30 min) increasing the surface levels of AMPAR, achieving a plateau at 1h, without altering endocytosis or total receptor mass, thus suggesting enhanced recycling. Even though protein kinase a (PKA) and N-methyl-D-aspartate receptor activity are known to increase post-synaptic levels of AMPAR, only PKA inhibitors decreased this effect. Focal Adhesion Kinase (FAK) inhibition also counteracted this effect, thus involving integrin activation. Electrophysiology assessing field excitatory post-synaptic potential and patch-clamp currents showed that Gal-8 increases AMPAR-mediated transmission. In concordance, Gal-8 knock-out mice displayed lower AMPAR levels on post-synaptic densities and impaired long-term potentiation (LTP) in hippocampal CA3-CA1 synaptic transmission, correlating with poor performance in spatial memory tests. Human anti-Gal-8 autoantibodies isolated from SLE patients alter LTP. All these results posit Gal-8 as a new modulator of AMPA receptor function, likely acting through integrins and PKA activation and impinging upon synaptic transmission and spatial memory. Autoantibodies that counteract Gal-8 function on glutamatergic transmission can potentially mediate cognitive dysfunction. (CONICYT Basal grant AFB170005. FWIS UNESCO-L'Oreal fellowship (MFB))

Parallel Processing of Two Mechanosensory Modalities by a Single Neuron in *C. Elegans*.

L. Tao, 94305[1], D. Porto[2], Z. Li[3], S. Fechner[1], S. Lee[2], M. B. Goodman[1], S. Xu[3], H. Lu[2], K. shen[1]; [1]Stanford University, Stanford, CA, [2]Georgia Institute of Technology, Atlanta, GA, [3]University of Michigan, an n Arbor, MI.

Neurons convert synaptic or sensory inputs into cellular outputs. It is not well understood how a single neuron senses, processes multiple stimuli, and generates distinct neuronal outcomes. Here we describe the mechanism by which the *C. elegans* PVD neurons sense two mechanical stimuli: external touch and proprioceptive body movement. These two stimuli are detected by distinct mechanosensitive DEG/ENaC/ASIC channels, which trigger distinct cellular outputs linked to mechanonociception and proprioception. Mechanonociception depends on DEGT-1 and activates PVD's downstream command interneurons through its axon, while proprioception depends on DEL-1, UNC-8 and MEC-10 to induce local dendritic Ca^{2+} increase and dendritic release of a neuropeptide NLP-12. NLP-12 directly modulates neuromuscular junction activity through the Cholecystokinin receptor homolog on motor axons, setting muscle tone and movement vigor. Hence, the same neuron simultaneously uses both its axon and dendrites as output apparatus to drive distinct sensorimotor outcomes.

VASP Ubiquitination Regulates Actin Dynamics and Neuronal Morphogenesis.

L. E. McCormick, G. H. Diering, S. L. Gupton; University of North Carolina at Chapel Hill, Chapel Hill, NC.

Filopodia are dynamic, actin-rich structures that extend outward from the cell and explore the local environment. In neurons, filopodia are critical for numerous stages of development, including neuritogenesis, axon guidance, and dendritic spine formation. Defects in any of these stages of neuronal development can result in improper synaptic connectivity, neurodevelopmental disorders, and psychiatric syndromes. The Ena/VASP of actin polymerases is well appreciated to localize to the filopodial tip complex and influence actin dynamics. Recently, the Gupton lab showed VASP transiently co-localizes with the E3 ubiquitin ligase TRIM9 at the filopodial tip. TRIM9 was required for the reversible, non-degradative ubiquitination of VASP and this modification was associated with decreases in filopodia stability and number at the growth cone. Although the dynamic actin cytoskeleton and VASP are also appreciated to play important roles in the postsynapse, it is not known how VASP activity is regulated in dendritic filopodia and the maturing dendritic spine. Here we show that VASP, TRIM9 and ubiquitinated VASP (VASP-Ub) localize to the PSD following differential centrifugation, suggesting a role for VASP-Ub in dendritic spines. Cultured murine cortical neurons lacking *Trim9* exhibit increased dendritic filopodia number at DIV7. Likewise, overexpression of VASP and a non-ubiquitinatable form of VASP (VASP-KR) also increase dendritic filopodia at DIV7. Based on these results, we hypothesize VASP-Ub is required for the regulation of actin dynamics during synaptogenesis. Ongoing work is examining *Trim9* deletion, as well as VASP and VASP-KR overexpression, on dendritic spine number and synaptic plasticity. Future work will explore the mechanistic impact of ubiquitination on actin-VASP interactions through in *vitro* biochemical reconstitution assays.

Neurofilament Transport Is Bidirectional in *Vivo* and Is Developmentally Regulated.

N. P. Boyer[1], P. Jung[2], A. Brown[1]; [1]The Ohio State University, Columbus, OH, [2]Ohio University, Athens, OH.

The postnatal development of long axons is characterized by an accumulation of space-filling cytoskeletal polymers called neurofilaments, which drives the expansion of axon caliber necessary for rapid electrical transmission. Studies in cultured nerve cells using fluorescence microscopy have shown that neurofilament polymers move bidirectionally along axons in a rapid intermittent manner and that they can spend as much as half their time moving backwards. However, it is unclear whether neurofilament movement is also bidirectional in *vivo*. To test this, we developed a pulse-spread assay which measures the rate of spreading of a population of photoactivated fluorescent axonal neurofilaments. Tibial and sciatic nerve segments were dissected from Thy1-PAGFP-NFM transgenic mice, which express PAGFP-tagged neurofilament protein M in neurons, and imaged in a perfusion chamber. The filaments were photoactivated in a short segment of an axon and the increase in the fluorescence of the proximal and distal flanking regions due to the movement of the fluorescent neurofilaments was measured over time. Using computational modeling, we show that the difference of the slopes of the fluorescence in the flanking regions yields the neurofilament transport velocity and that the ratio of the proximal and distal slopes yields the directional bias. Our data demonstrate active bidirectional transport of neurofilaments in myelinated axons from mice at 2, 4, 8 and 16 weeks of age, with a substantial fraction moving retrogradely. The neurofilament transport rate decreased with age, which is consistent with previous reports obtained using radioisotopic pulse labeling. Approximately 55% of the transport was anterograde in mice aged 2, 4, and 8 weeks, while no directional bias was detected at 16 weeks. Thus, we conclude that neurofilament transport is bidirectional in *vivo and* that the filaments spend a significant fraction of their time moving retrogradely. The lack of directional bias at 16 weeks suggests that there is no net movement of the polymers in distal axons of older animals. It is intriguing that axons invest metabolic energy to move neurofilaments backwards, and it suggests that neurofilament transport does not function only to deliver neurofilaments to distal regions of axons. It is possible that the retrograde movement is important for neurofilament turnover or degradation, but we favor the idea that the bidirectional movement of these polymers may function more to distribute and/or organize these polymers.

Neurite Morphogenesis Requires Suppression of the Lamellar Protrusions of the Cell Body by Septin 7.

M. R. Radler, E. Spiliotis; Drexel University, Philadelphia, PA.

Axons and dendrites, the structures that transmit and receive electrical and chemical signals in the brain, develop from the membrane protrusions of neuronal cell bodies. Formation of neurites, the early precursors of axons and dendrites, involves the formation of actin-rich filopodia and their engorgement with microtubules. How actin and microtubules are coordinated and how neurites mature and grow asymmetrically into axons and dendrites is not well understood. Septins are a family of filamentous GTP-binding proteins, which associate with actin and microtubules, and septin 7 (Sept7) was recently found to determine the sites of neurite formation in neuronal progenitors. Here, we have sought to investigate the role of septins in early neurite formation and asymmetry establishment. We found that that Sept7 depletion in embryonic rat hippocampal neurons (DIV1) resulted in neurons with abnormally enlarged

cell bodies, which lacked pyramidal-shaped morphology and characterized by extensive lamellipodia-like protrusions. Strikingly, several neurites were observed to extend directly from these lamellipodial protrusions rather than directly from the cell body. This phenotype was accompanied by a reduction in the number of neurons that broke neurite symmetry and developed a single elongated tau-positive neurite, the presumptive axon. Expression of the constitutively active myosin II regulatory light chain in Sept7-depleted cells rescued partially the size and shape of neuronal cell bodies, and restored neurite formation from the cell body as well as axonal specification. Taken together, our data suggest that Sept7 functions synergistically with myosin-II in suppressing membrane protrusive activity and possibly branched actin polymerization, restricting neurite growth and maturation to filopodia that are in direct continuum with the cell body.

Doublecortin Supports Growth Cone Microtubule Function in Early Neuronal Morphogenesis.

R. Charafeddine, T. Wittmann; University of California, San Francisco, San Francisco, CA.

Numerous familial and spontaneous mutations in Doublecortin (DCX), a microtubule-associated protein highly expressed in the developing nervous system, cause a spectrum of debilitating neurodevelopmental conditions, such as X-linked Lissencephaly or Subcortical Band Heteropia. It is thought that DCX mutations disrupt the migration of immature neurons through the developing cortex. However, the molecular role of DCX in early neuronal development and how DCX controls organization and function of the neuronal microtubule cytoskeleton is not well understood and is mostly based on in vitro experiments or overexpression of DCX in non-neuronal cells. To directly investigate DCX function and dynamics at endogenous expression levels in developing neurons, we fluorescently tagged the C-terminus of the endogenous DCX locus in human induced pluripotent stem cells (iPSCs) by CRISPR/Cas9 genome editing. Developing DCX-eGFP iPSC-derived neurons show a similar increase of DCX expression as control cells, and time-lapse microscopy of DCX-eGFP confirms our previous finding of DCX-eGFP specificity for straight GDP-lattice microtubules. Notably, we never observe DCX-eGFP tracking of growing microtubule ends and never observe bundling of DCX-eGFP labeled microtubules. However, we find that DCX-eGFP only binds to microtubules in neuronal growth cones or nascent branches along the neurite shaft. Inhibition of DCX-microtubule binding in the neurite shaft may be due to phosphorylation, as pharmacological inhibition of glycogen synthase kinase 3 (GSK3) increased DCX localization to neurite microtubules. We previously found that taxanes reverse the microtubule geometry specificity of DCX. Based on experiments in which taxanes induce characteristic bending of neuronal growth cone microtubules, we hypothesize that DCX functions to straighten and/or stiffen microtubules in advancing growth cones. To directly test this hypothesis and test at a molecular level how disease-associated DCX mutations impede nervous system development, we are now modeling clinical DCX mutations in our iPSC neuronal differentiation system.

Modifying Levels of Acetylated Microtubules in Growth Cones Triggers Redistribution of Eb3.

M. Sindoni, E. Welnhofer Hogan; Canisius College, Buffalo, NY.

In the peripheral domain of growth cones, interactions between F-actin and dynamic microtubules influence growth cone behavior and direction of axon advance. Our previous research showed an

inverse relationship between levels of microtubule acetylation and microtubule invasion into the peripheral domain, but the mechanism of why this occurs is not known. EB3, a microtubule plus-end tracking protein, plays an important role in promoting the interaction between dynamic microtubules and F-Actin in the peripheral domain of growth cones. Here, we tested if modifying the levels of microtubule acetylation would affect the localization of EB3 in growth cones. To increase the amount of acetylated microtubules (AcMTs), we used tubacin, a cell-permeable inhibitor of HDAC6, an enzyme that removes acetyl groups from MTs. To decrease the amount of AcMTs, we used resveratrol, an activator of sirtuin, an enzyme that de-acetylates microtubules. Following exposure to either tubacin or resveratrol, *Helisoma* neurons were immunostained with antibodies for EB3 and tubulin. Quantification of fluorescent intensity in neurons exposed to tubacin showed a significant increase in the amount of EB3 present in the filopodia compared to control cells, while neurons exposed to resveratrol showed a significant decrease in the amount of EB3 present in the filopodia compared to control cells. Additionally, threshold analysis of EB3 fluorescence in the peripheral domain revealed that as the levels of AcMTs increased, the levels of EB3 decreased. These results suggest that microtubule acetylation promotes redistribution of EB3, resulting in suppression of EB3 interactions with microtubules.

CB1R and Myosin II Function in Regulation of Growth Cone Protrusions and Axon Projections in the Optic Tract.

T. Elul; Touro University California, Vallejo CA, CA.

A key step in the formation of neuronal circuits involves axons navigating through diverse regions of the brain to their target tissue. In the developing retino-tectal projection of lower vertebrates, optic axons extend through the optic tract towards the optic tectum in the midbrain. Here, we studied how the main cannabinoid receptor in the brain- CB1R- and the actin regulator Myosin II modulate optic axon pathfinding and growth cone filopodia in the optic tract in brains of *Xenopus* tadpoles. Embryos and tadpoles containing GFP optic axons were bathed in chemical inhibitors specific for CB1R (AM251) or Myosin II (Blebbistatin) during developmental stages when optic axons normally extend through the optic tract. The tadpoles were then fixed and their brains were dissected, and the optic axons were imaged in the optic tract of whole brains. These experiments showed that AM251 increased dispersion and induced aberrant turning of optic axons away from the optic tectum. In contrast, Blebbistatin inhibited the extension of optic axons through the optic tract. However, optic axons from tadpoles exposed to both the CB1R and Myosin II inhibitors formed growth cones with increased numbers of filopodial protrusions. These results suggest that CB1R and Myosin II exert both shared and distinct functions in regulating growth cone filopodia *and* optic axonal projections *in* the optic tract. More broadly, our findings imply that optic axonal growth cones may express distinct types of filopodia that regulate specific axon pathfinding behaviors such as fasciculation and extension.

A Mechanism for Neurofilament Transport Acceleration through Nodes of Ranvier.

M. Ciocanel[1], P. Jung[2], A. Brown[1]; [1]The Ohio State University, Columbus, OH, [2]Ohio University, Athens, OH.

Neurofilaments are abundant space-filling cytoskeletal polymers in axons that are transported along microtubule tracks. Experiments show that neurofilament transport is accelerated at nodes of Ranvier,

where axons are locally constricted. Strikingly, these constrictions are accompanied by a sharp decrease in neurofilament number but no decrease in microtubule number, bringing neurofilaments closer to their microtubule tracks. In this work, we test the hypothesis that improved access to microtubules leads to an increase in the proportion of the time that the filaments spend moving and that this can explain the local acceleration. We developed a stochastic model of neurofilament transport that takes into account neurofilament length distribution and tracks their number, kinetic state and proximity to nearby microtubules in space and time. The model assumes that the probability of a neurofilament actively moving is dependent on its distance from the nearest available microtubule track. We use experimentally reported numbers and densities for neurofilaments and microtubules in axonal nodes and internodes and show that this model is sufficient to explain the local acceleration of neurofilaments across nodes of Ranvier. The proposed modeling framework can be used to predict and illustrate the impact of filament length distributions and neurofilament to microtubule ratios on the ability of neurofilaments to navigate these physiologically important axonal constrictions. Our results suggest that proximity to microtubule tracks may be a key regulator of neurofilament transport in axons, which has implications for the mechanism of neurofilament accumulation in development and disease.

P492/B504

Kinetochore Protein Spindly Controls Microtubule Polarity in Axons by Recruiting Dynein to F-actin.

U. Del Castillo[1], H. J. Müller[2], V. I. Gelfand[1]; [1]Dept. Of Cell and Developmental Biology, Feinberg School of Medicine, Northwestern University, Chicago, IL, [2]Developmental Genetics at the Institute of Biology, University of Kassel., Kassel, GERMANY.

Polarity of microtubules in axons and dendrites defines intracellular transport in neurons. Axons contain uniform microtubule arrays with plus-ends facing the tips of the processes, while dendrites contain microtubules with a minus-end-out orientation. We have recently demonstrated that cytoplasmic Dynein, targeted to cortical actin, removes minus-end-out microtubules from axons. Here we have identified Spindly, a protein who's known role is to recruit Dynein to the kinetochore in mitosis, as a key factor of in Dynein-dependent sorting of microtubules in axons of *Drosophila* neurons. Depletion of Spindly affects polarity of axonal microtubules in *vivo* and in primary neuronal cultures. In addition to axonal microtubule polarity defects, depletion of Spindly in neurons causes major collapse of axonal patterning in third instar larvae brains as well as dramatic locomotion and coordination impairment in adult flies. These phenotypes can be fully rescued by ectopic expression of wild-type Spindly, but not by variants with the mutation in the dynein-binding site. Biochemical analysis demonstrated that Spindly binds F-actin, confirming that Spindly serves as a link between Dynein and cortical actin in axons. Thus, a "mitotic" protein Spindly plays a critical role during neurodevelopment by facilitating Dynein-driven sorting of axonal microtubules. Supported by NIGMS grants GM-052111 and GM-131752 to VIG

P493/B505

Radial Axonal Growth and Slowing of Neurofilament Transport.

A. Friedman[1], A. Brown[2], P. Jung[1]; [1]Department of Physics and Astronomy and Quantitative Biology Institute, Ohio University, Athens, OH, [2]Department of Neuroscience, Ohio State University, Columbus, OH.

The radial growth of axons during postnatal development is an important influence on axonal conduction velocity. This axonal expansion is driven in part by the accumulation of space-filling

cytoskeletal polymers called neurofilaments. Neurofilaments are delivered to axons by molecular motors, which transport the filaments rapidly but infrequently along microtubule tracks. The filaments move forwards and backwards, but with an anterograde bias, resulting in a slow net velocity of 0.1-2 mm/day towards the axon tip. Experimental studies have shown that the neurofilament accumulation is accompanied by an increase in neurofilament expression, which suggests an increase in neurofilament flux from the cell body, and a slowing of neurofilament transport velocity within the axon. We have used computational modeling to investigate the cause of this slowing and its contribution to radial axon growth. In our model, neurofilaments enter the axon proximally and move along microtubules, cycling through kinetic states in which they move either anterogradely or retrogradely or pause. We consider that the neurofilaments are radially mobile and that they must make a diffusive encounter with a microtubule in order to move. Thus, the probability of moving is inversely proportional to the average distance between the neurofilament and its nearest microtubule. To model radial growth, we adjusted the influx of neurofilaments, which has not been directly measured, to match the observed neurofilament content and axonal caliber during the postnatal development of the rat sciatic nerve. We increased the number of microtubule tracks according to published morphometric data. We then used this model to simulate the movement of a pulse of radiolabeled neurofilaments along the axon at different stages of postnatal development. We found that initially the velocity of the pulse is much faster than the average velocity of the overall neurofilament population regardless of whether there is radial growth. The pulse slows down to the average neurofilament velocity within a few days. We also found that the slowing of the average neurofilament velocity during postnatal development emerges in the model because the increase in neurofilaments outpaces the increase in microtubules, increasing the average distance of the neurofilaments from their nearest microtubule track. Our analysis indicates that the growth and maintenance of axon caliber is a complex interplay of neurofilament flux from the cell body and transport velocity within the axon. The model permits us to estimate the relative contribution of an increase in neurofilament flux and a decrease in neurofilament transport velocity to the growth of axon caliber.

Local Regulation of Microtubule Organization and Synaptic Cargo Delivery by an Immotile Kinesin.

S. B. Gomez, **S. Yogev**; Yale University, New Haven, CT.

Acentrsomal microtubule arrays support long-range transport of neuronal cargo. How properties of neuronal microtubules - array density, polymer length, dynamics and distribution - are regulated, and how they affect the delivery of synaptic cargo, is poorly understood. We established an experimental system to examine microtubule organization, dynamics and cargo delivery in *vivo*, with single-cell resolution in living *C. elegans* nematodes. From an unbiased genetic screen, we identified the immotile kinesin VAB-8/KIF26 as a regulator of neuronal microtubule organization. *vab-8* mutants show specific and local microtubule organization defects at proximal presynaptic varicosities, including reduced polymer numbers and increased polymer length. Surprisingly, axonal transport does not stall on these abnormal tracks, but vesicles instead accumulate in more distal presynaptic sites, suggesting a specific failure in synaptic cargo delivery. VAB-8/KIF26 is known to regulate cell migration downstream of Wnt signaling. We found that in the context of patterning synaptic connectivity, VAB-8/KIF26 also acts downstream of the Frizzled receptor, and identified mutations in a Frizzled receptor E3 ligase, PLR-1/RNF43 that lead to identical microtubule and transport defects as *vab-8*. We propose that local

regulation of acentrosomal microtubules by extracellular cues ensures robust cargo delivery and patterning of synaptic connectivity.

Neuron Development and Functioning Depends on the Proper Microtubule Organization; a Balancing Act between Sliding and an choring.

L. He[1], R. Kooistra[1], R. Das[2], E. Oudejans[1], E. V. van Leen[1], J. Ziegler[2], S. Portegies[1], B. de Haan[1], A. S. van Regteren Altena[1], R. Stucchi[1], M. A. F. Altelaar[1], S. Wieser[2], M. Krieg[2], C. C. Hoogenraad[1], **M. Harterink**[1]; [1]Utrecht University, Utrecht, NETHERLANDS, [2]ICFO-Institut de Ciencies Fotoniques, Barcelona, SPAIN.

The proper organization of the microtubule cytoskeleton is essential for neuronal development and survival. The microtubules serve as tracks for long range cargo transport and enable for selective transport into the axon and dendrites to establish neuronal polarity. In addition, the regulation of microtubule integrity is tightly linked to neuron survival and regeneration. Even though crucial for proper neuronal functioning, the molecular mechanisms that set-up and maintain the microtubule organization are for a large part unclear. Here, we use *Caenorhabditis elegans* as an in *vivo* model system to study neuron development and found that UNC-119 (homologous to human UNC119A and UNC119B) is essential microtubule organization in axons and dendrites. By binding to the cortical UNC-44 (Ankyrin) and the microtubule binding UNC-33 (CRMP), UNC-119 forms a periodic membrane-associated cytoskeletal complex that anchors the plasma membrane to the underlying microtubule cytoskeleton. In the absence of either of these proteins, the microtubule cytoskeleton shows dramatic sliding and becomes disorganized, resulting in axon-dendrite polarity defects. This sliding is induced by the motor protein UNC-116 (kinesin-1), which in wildtype animals is essential for dendritic microtubule organization. We propose that the proper development of axons and dendrites relies on a balance between motor induced microtubule sliding and anchoring to the plasma membrane.

P496/B508

Growing Tip-localized Microtubule Organizing Center Determines Microtubule Orientation in Dendrites.

M. Kokes[1,2], X. Liang[1,2], M. A. Pickett[1], M. D. Sallee[1], J. L. Feldman[1], K. Shen[1,2]; [1]Stanford University, Stanford, CA, [2]Howard Hughes Medical Institute, Stanford, CA.

Neuronal subcellular compartmentalization of axon and dendrite provides a directionality that is essential for informational flow through the nervous system, and how it is established remains unclear. By observing the development of a single highly polarized neuron from its birth in *C. elegans*, we find it polarizes and outgrows its axonal and dendritic neurites with highly stereotyped orientation and sequence. The unique behavior of each neurite even as it first emerges suggests that the establishment of subcellular compartmentalization is concomitant with neurite emergence in *vivo* rather than a delayed neurite maturation process as is seen in cultured neurons removed from their in *vivo* environment. As tracks for directional subcellular transport, a polarized arrangement of microtubule arrays lays the foundation for axon versus dendrite compartmentalization. Mature axons are characterized by exclusively “plus-end-out” microtubules while dendrites uniquely contain a large population of “minus-end-out” microtubules. Here we identify a mechanism by which the characteristic minus-end-out microtubule orientation is initially established in dendrites. By observing microtubule plus-end growth during dendrite emergence and outgrowth, we find a microtubule-organizing center

(MTOC) that localizes near the distal dendrite tip as it emerges and continues to advance. This MTOC generates numerous minus-end-out microtubules that populate the dendrite. Core components of the gamma tubulin ring complex localize to the dendritic MTOC. Cell-specific degradation of these components indicates they are required for the dendritic MTOC and establishment of the minus-end-out microtubules characteristic of mature dendrites. We continue to characterize the subcellular nature, regulation, and positioning of this growing tip-localized dendritic MTOC.

P497/B509

Laser-induced Severing Reveals Evidence for a Preferential Association of Motors with the Leading Ends of Moving Neurofilaments.

A. Uchida, A. Brown; Ohio State Univ-Dept Neurosci, Columbus, OH.

Neurofilaments are long flexible cytoskeletal polymers that are transported rapidly and intermittently along axonal microtubule tracks powered by kinesin and dynein motor proteins. Time-lapse and kymograph analyses of neurofilaments in axons of cultured neurons have revealed that these polymers often fold and unfold reversibly, however, they almost always become fully extended when they move. To explain this behavior, we hypothesize that neurofilaments are pulled from their leading ends, which implies that neurofilament motors associate preferentially with the leading ends of these polymers. To test this hypothesis, we used a nanosecond-pulsed dye laser to sever single moving neurofilaments in axons and examined the fate of the severed fragments. If motors associate exclusively with the leading end of the moving filaments then we would expect that the leading fragment would continue to move and the trailing fragment would not. Neurofilaments in primary cultures of rat cortical neurons were transfected with GFP-tagged neurofilament protein L to label neurofilament polymers and the movement of the polymers was tracked by time-lapse imaging with 100 ms exposures and 2-3 second time intervals. Moving neurofilaments were irradiated on the fly by 1-5 nanosecond pulses of 435 nm light delivered using an an dor MicroPoint laser. The GFP fluorescence on the filament was bleached immediately, marking the site of irradiation. By attenuating the intensity of the laser, we were able to induce delayed severing, permitting the filaments to move away from the original axonal location of irradiation before they severed. In this way, we were able to avoid any concern about possible damage to the axon or microtubule tracks at the location of filament severing. After severing, we tracked the fate of the filament fragments. 58% of the time (26/45 filaments) only the leading end continued to move and the trailing end did not. 20% of the time (9/45 filaments) only the trailing end moved and the leading end did not. 22% of the time (10/45 filaments) both the leading and trailing ends moved. Interestingly, when the leading end moved, 92% of the time (33/36 filaments) it continued to move in the same direction as the filament was moving before it severed, but when the trailing end moved, 73% (12/19) of the time it moved in the opposite direction that the filament had been moving before it severed. These observations suggest that (1) motors associate preferentially, but not exclusively, with the leading ends of moving neurofilaments, (2) there can be multiple sites of motor attachment along the moving filaments, and (3) motors of opposite directionality can associate with the same moving filament, sometimes at opposite ends.

P498/B510

Spatiotemporal Optogenetic Control of Microtubule Dynamics during Neuronal Morphogenesis.

J. van Haren[1], R. Charafeddine[2], T. Wittmann[2]; [1]Erasmus MC, Rotterdam, NETHERLANDS, [2]UCSF, San Francisco, CA.

Neurons are amongst the most highly polarized and elongated cell types found in animals, and this morphology depends on the proper regulation of the microtubule (MT) cytoskeleton which provides structural support, and forms an intracellular railway system required to generate and sustain polarity. MTs are critical for many aspects of neuronal morphogenesis, such as neurite elongation, branching and neuronal navigation. MTs, while very rigid structures, are also highly dynamic, in order to support rapid reorganization and morphological plasticity. Directional navigation of neurons is mediated by the neuronal growth cone which senses and responds to chemotactic guidance cues, and this process depends on dynamic pioneering MTs in the growth cone periphery that polarize in the direction of migration. While it was demonstrated that this is related to the activation of Rho GTPases (key regulators of the actin cytoskeleton), it remains unclear how local regulation of MT dynamics controls growth cone steering. To gain a better understanding of this process, we have generated iPSC-derived neurons in which we can spatially control the activity of an important regulator of MT dynamics (the +TIP EB1) by light. We accomplished this via a single step genome editing strategy, that allowed us to directly insert a photo-inactivation element into the EB1 gene. We demonstrate that the growth rate of MTs in pi-EB1 knock-in iPSCs is not significantly different from WT cells in the dark, but decreases upon blue light inactivation of pi-EB1, similar to our previous results in other cell types. pi-EB1 expressing iPS cells could be efficiently differentiated into glutamatergic neurons, and allowed us to locally inactivate the +TIP complex in neuronal growth cones by using patterned blue light illumination. By confining the growth of these neurons to precisely controllable adhesion patterns we are now able to test the role of MT dynamics during neuronal growth cone migration in a highly standardized manner.

P499/B511

Unique β-spectrin N-terminus Is Required for Actin Binding and Neuronal Morphogenesis.

S. A. Denha[1], T. S. Hays[2], A. W. Avery[1]; [1]Oakland University, Rochester, MI, [2]University of Minnesota, Minneapolis, MN.

Beta-spectrin binds actin to form a sub-plasma membrane cytoskeleton that is required for neuronal morphogenesis. We recently demonstrated that binding of beta-spectrin to actin is enhanced 1000-fold by a spinocerebellar ataxia type 5 (SCA5) L253P mutation that opens the interface between the tandem calponin homology (CH) subdomains comprising the ABD, allowing CH1 to directly bind actin. In addition, we identified a unique N-terminal sequence, preceding the conserved ABD, which also binds actin. The objective of the current study is to determine the functional requirement of the N-terminus for actin binding and beta-spectrin function in neurons. Using in vitro binding assays, we found that the high actin affinity of the mutant L253P ABD is abolished by N-terminal truncation. Thus, the N-terminus is required for actin binding even in the presence of a mutation that induces opening of the CH interface. To test the function of the N-terminus in vivo, we generated new Drosophila lines expressing beta-spectrin transgenes with N-terminal truncations (delta N). Pan-neuronal expression of delta-N-beta-spectrin causes toxicity. In contrast, N-terminal truncation eliminates toxicity caused by L253P mutation, consistent with a function of the N-terminus to modulate actin binding. To examine functional requirement of the N-terminus in neuronal morphogenesis, beta-spectrin transgenes were expressed

specifically in peripheral class IV da neurons. Delta-N-beta-spectrin causes severe loss of dendritic arborization, consistent with a toxic function of the truncated protein. In contrast, N-terminal truncation rescues arborization defects caused by the L253P mutation. In conclusion, our data suggest that opening of the CH1-CH2 interface is not sufficient to induce actin binding. Instead, the binding mechanism requires the unique N-terminus. Further, the N-terminus is essential for spectrin function in vivo to support formation of complex dendritic arbors.

P500/B512

A Charcot-Marie-Tooth Disease Type 2E Point Mutation in Neurofilament Protein L (NFL) Causes Altered Neurofilament Protein Levels and Impaired Neurofilament Assembly in Vivo.

E. J. Stone, A. Uchida, P. C. Monsma, A. N. Sheldon, A. Brown; the Ohio State University, Columbus, OH.

Neurofilaments are neuron-specific cytoskeletal polymers that contribute to axon expansion during development. The five subunits of neurofilaments are NFL, NFM, NFH, α-internexin, and peripherin. Charcot-Marie-Tooth disease type 2E (CMT2E) is a slowly progressive peripheral neuropathy of unknown mechanism caused by mutations in the gene that encodes NFL. The $NFL^{N98S/+}$ CMT2E mouse model, which is heterozygous for the N98S mutation in the endogenous mouse Nefl locus, has a disease phenotype and offers an opportunity to study the effects of a CMT2E mutation on neurofilaments in vivo. With this mouse we can ask several questions: 1) Is the mutant protein stably expressed? 2) Is the mutant protein incorporated into filaments? 3) Are the expression levels and assembly of the other neurofilament subunits altered? Protein quantification in spinal cord by Western blotting revealed a moderate reduction of NFL, NFM and α-internexin, a moderate increase of NFH, and a marked increase of peripherin. In contrast, quantification in the sciatic nerve revealed a marked reduction of NFL, NFM, NFH and α-internexin and a lesser reduction of peripherin. Using tandem mass spectrometry of tryptic digests, we determined that 41% of the NFL protein in the spinal cord was the N98S mutant protein. To determine the assembly state of the neurofilament proteins, we homogenized spinal cord tissue in Triton X-100 and performed centrifugation to separate soluble (unassembled) and insoluble (assembled) fractions. In the mutant, we observe an elevation of neurofilament proteins in the Triton-soluble fraction and a reduction in the Triton-insoluble fraction. On average, 41% of the NFL protein in the soluble fraction was mutant compared to 30% in the insoluble fraction. Electron microscopy of spinal cord, dorsal root ganglia and sciatic nerves confirmed that most myelinated axons lacked neurofilaments and exhibited reduced caliber, but some axons in the dorsal root ganglia and spinal cord were enlarged and contained neurofilament accumulations. Our data suggest that expression of the mutant NFL results in an impairment of neurofilament assembly in the spinal cord and a profound loss of neurofilament proteins and neurofilaments in peripheral nerve myelinated axons. The loss of NFL protein in the spinal cord is due to a loss of both mutant and wild type protein. Thus, there does not seem to be a selective destabilization of the mutant protein. We hypothesize that disease may arise from a failure of neurofilaments to enter axons due to sequestration and destabilization of neurofilaments in cell bodies and proximal axons caused by either (1) alterations in the structure or subunit stoichiometry of the filaments, or (2) toxicity or gain-of-function of elevated soluble neurofilament protein.

Establishing and Maintaining an Organelle 1

The Cell Atlas in the Human Protein Atlas: an Image-based Subcellular Map of the Human Proteome.

P. J. Thul, U. Axelsson, J. Fall, C. Gnann, R. Schutten, L. Åkesson, A. Bäckström, M. Hjelmare, D. Mahdessian, C. Stadler, C. Winsnes, H. Xu, M. Uhlén, E. Lundberg; Human Protein Atlas/Science for Life Laboratory (KTH), Stockholm, SWEDEN.

The spatial division into organelles and other subcellular structures is the defining principle of the eukaryotic cell. This concept allows multiple reactions to occur in parallel in an optimized and often enclosed environment. Each of these organelles has its own proteome for fulfilling the respective function at a specific time and place. Hence, knowledge of the subcellular localization of a protein is an essential step in its characterization and can provide evidence about potential functions and interactions. The publicly available Cell Atlas, part of the Human Protein Atlas (HPA) database, is a valuable resource designed for researchers that are interested in the spatial distribution of proteins. We generated the most comprehensive map of human protein distribution, which is based on ten thousands of immunofluorescent images. For that, we used the large HPA antibody collection, which contains antibodies targeting all human proteins. The updated HPA Cell Atlas covers now 12,390 proteins mapped to 33 subcellular locations, enabling the definition of 13 major organelle proteomes. The high spatial resolution of the IF images enabled the identification of novel protein components of fine structures such as the midbody, nuclear bodies or rods and rings. The image data is complemented by RNA sequencing data for 64 cell lines of various tissue origins, connecting gene expression and cell line-specific characteristics with subcellular localization. One major finding was the discovery of many new multilocalizing proteins (MLPs). MLPs are proteins which are detected at more than one organelle. Approximately half of the analyzed proteins were MLPs (6647), with 29% of them (1960) at three or more locations, confirming that multilocalization is a common feature of the human proteome. An other key feature of the HPA Cell Atlas is the possibility to look at single cell variations. About a fifth of the analyzed proteins showed spatial or quantitative variations in the protein expression and further analysis demonstrated that only a subset of variations could be linked to the cell cycle. Furthermore, we implemented the localization data from the HPA Cell Atlas to a protein-protein interaction network and thereby improved its quality. This indicates that other network analyses could benefit comparably. Finally, the IF images have been successfully used in the training of various models for image classification, underlining the high quality of images. The HPA Cell Atlas provides in combination with the other HPA sub-atlases for humantissues, brain, blood and cancer a holistic view on the human proteome in health and disease.

The Properties of Membraneless Organelles Are Tuned to Environmental Conditions.

B. Stormo[1], F. Dietrich[2], C. Roden[1], A. Gladfelter[1]; [1]University of North Carolina-Chapel Hill, Chapel Hill, NC, [2]Duke University, Durham, NC.

How cells pattern and compartmentalize their cytoplasm is a critical question in biology. Many cells rely on membraneless organelles for organizing biochemistry. These organelles are not separated from the rest of the cell by a lipid bilayer, instead they are formed through Liquid-Liquid Phase Separation (LLPS) in which a well-mixed solution demixes into a concentrated droplet phase and a dilute bulk phase. When the material properties, such as viscosity, of these droplets are measured they are found to vary by a thousand fold. Despite these differences we have very little understanding about whether specific properties are important for the function of droplets, although it has been suggested that dysregulation of droplet properties can result in diseases. In the free-living filamentous fungus *Ashbya gossypii* asynchronous nuclear division in the syncytial hyphae requires the phase separation of the protein Whi3 and the cyclin RNA *CLN3*. Whi3 also undergoes phase separation with the polarity RNAs *BNI1* and *SPA2*, which is required for hyphal branching. Like other phase-separating proteins Whi3 contains an RNA recognition motif (RRM) that allows for multivalent interactions, and it contains a disordered domain rich in glutamine (polyQ). Loss of either of these domains results in failure to phase separate. Because LLPS is a thermodynamically-driven process, temperature plays a role in determining whether phase separation happens and influences the properties of the resulting droplets. Free living fungi are exposed to the ambient temperature and therefore are under selective pressure to adapt to their local climate. We hypothesized that if the material properties of droplets are important then they should be optimized for a given climate. Using a collection of fifty wild-isolated *Ashbya* from different climates in the United States we sought to test the effects of temperature on the properties of membraneless organelles. We found that the interbranch distance, which is controlled by membraneless organelles, varied between isolates when grown at high or low temperature. We then performed whole genome sequencing on the wild isolates. We found that the sequence of the Whi3 polyQ domain, which is critical for phase separation, differs between isolates and that purified proteins from these isolates behaves differently in *in vitro* phase separation experiments. We further found that the sequence of the RNA of *CLN3* and *BNI1* differs between isolates and that these changes affect the structure of those RNAs without changing the protein coding sequence. These results suggest that the material properties of phase separated droplets are tuned to the climate at which the cells live indicating that specific properties are important for function.

Coupled Oscillators Self-organise the Assembly of Centrioles.

L. E. Hankins[1], M. G. Aydogan[1], S. Saurya[1], T. L. Steinacker[1], A. Wainman[1], F. Echegaray-Iturra[2], J. Dobbelaere[3], X. Lu[4], F. Y. Zhou[4], J. W. Raff[1]; [1]Sir William Dunn School of Pathology, University of Oxford, Oxford, UNITED KINGDOM, [2]University of Sussex, Brighton, UNITED KINGDOM, [3]Max F. Perutz Laboratories, Vienna Biocenter, Vienna, AUSTRIA, [4]Ludwig Institute for Cancer Research, University of Oxford, Oxford, UNITED KINGDOM.

The regulation of organelle biogenesis is a vital task. Centrioles are membraneless organelles, comprising a central cartwheel surrounded by microtubule (MT) blades. During centriole biogenesis, the cartwheel and MTs grow from opposite ends of the organelle, but ultimately reach the same size/ratio.

This study aims to address how this is achieved. We previously identified an autonomous Polo-like kinase 4 (Plk4) oscillator concentrated at the base of growing daughter centrioles, which times and executes cartwheel growth from this proximal-end. Here, we discover a CP110/Cep97 protein complex forms a separate autonomous oscillator at the tip of the daughter centriole, which appears to time the growth of the centriolar MTs at the distal-end. Remarkably, although spatially separated, the Plk4 and CP110/Cep97 oscillators are temporally coupled, ensuring the coordinated growth of the cartwheel and MTs. Coupled oscillators provide a novel, powerful mechanism for timing and coordinating the assembly of this complex organelle and might represent a more general feature of organelle biogenesis.

P505/B518

Testing the Constancy of the Nuclear to Cell (N/C) Volume Ratio in Chlamydomonas.

D. Liu[1,2], J. Umen[1]; [1]Donald Danforth Plant Science Center, Saint Louis, MO, [2]University of Missouri - St. Louis, Cell and Molecular Biology Program, Saint Louis, MO.

Maintenance of a constant nuclear to cell volume ratio (N/C) is a conserved trait in eukaryotic cells, though the absolute N/C ratio varies by species and by cell type. The green alga *Chlamydomonas reinhardtii* (Chlamydomonas) uses a multiple fission mitotic cell cycle where cells have a long G1 phase, during which they can grow more than ten-fold in size. G1 is followed by rapid alternating rounds of DNA syntheses and mitosis (S/M) to produce a uniform-sized population of new daughters. We took advantage of the large cell-size range observed in synchronized Chlamydomonas cultures to test the limits of N/C across different cell sizes. N/C was tracked in live cells using a nuclear-localized ble-GFP fusion protein as an in *vivo* marker for nuclei. We found that N/C remains nearly constant at around 5% across the cell cycle in wild-type haploid and diploid cells, and in cell-size mutants. By comparison, the shoot meristem cells and epidermal cells of Arabidopsis have an N/C ratio of 20%. The 135 Mb Arabidopsis genome is only slightly larger than that of Chlamydomonas (120 Mb) indicating that genome size is not the major parameter which sets N/C. We also observed a distortion of N/C in the smallest Chlamydomonas cells suggesting that there may be a lower limit of N/C constrained by the physical packing of DNA. Tests of the lower limit for N/C in diploid cells, which was higher than in haploid cells, supported the idea that N/C becomes physically constrained by nuclear DNA content in very small cells.

P506/B519

The Role of Osmotic Forces in Nuclear Size Control In*S.pombe*.

J. LEMIERE[1], M. Delarue[2], L. Holt[3], F. Chang[1]; [1]UCSF, Department of Cell and Tissue Biology, San Francisco, CA, [2]CNRS, Laboratoire d'Analyse et d'Architecture des systèmes, Toulouse, FRANCE, [3]NYU Langone Health, Institute for Systems Genetics, New York, NY.

The size of the nucleus scales with cell size so that the nuclear-to-cell volume ratio (NC Ratio) is maintained during cell growth. The mechanism responsible for this scaling is unknown. Nuclear volume is not determined merely by DNA amount, but is influenced by factors such as the surface area of the nuclear envelope, nuclear transport and osmotic pressure. Very little is known about mechanical basis underlying nuclear size control. Intracellular pressures may derive partially from "colloid osmotic forces" from nucleic acids and other macromolecules, and thus may correlate with the degree of macromolecular crowding. As new way to measure crowding of the cytoplasm and nucleoplasm, we use micro-rheology with Genetically-Encoded Multimeric nanoparticles (GEMs) as tracer probes. Here, we tested the role of forces (and crowding?) in nuclear size control. Addition of an osmotic agent (sorbitol)

caused a decrease in both nuclear and cell volume, but NC ratio was maintained. This suggests osmotic forces in the nucleoplasm and in the cytoplasm are roughly similar. Diffusion coefficients of GEMs showed that the nucleoplasm is normally slightly less crowded than the cytoplasm. To probe the mechanism of nuclear scaling, we investigated two cases where the NC ratio is perturbed. First, we characterized the effects of compressive force on live cells using a microfluidics device in which cell proliferation in a closed container leads gradual increase in external pressure. Under compression, cells exhibited a decrease in cell and nuclear size with a significant decrease in NC ratio. Crowding was increased both in the cytoplasm and nucleoplasm, suggesting a model in which increased pressure (both mechanical and chemical) squeezes the nucleus to decrease the NC ratio. Second, we inhibited nuclear export by leptomycin B to increase the NC ratio. Initially, the nucleus expanded with increased crowding in the nucleoplasm but not cytoplasm. Subsequently, the NC ratio continued to increase as the cell grew in volume, but crowding decreased in both compartments. This case lead to a model in which nuclear size may emerge from relationships between mechanics, NC transport, biomass synthesis, membrane tension and volume growth. Together, our findings show how forces from outside the cell as well as those in the cytoplasm and nucleus contribute to nuclear size.

P507/B520

Vacuole-Nuclear Envelope Organelle Contacts Promote Proper Nuclear Pore Assembly in Several Nucleoporin Mutants.

C. Lord, S. Wente; Vanderbilt University, Nashville, TN.

Title: Vacuole-nuclear envelope organelle contacts promote proper nuclear pore assembly in several nucleoporin mutants **Abstract**: the nuclear envelope (NE) is composed of two lipid bilayers that separate the nucleus from the cytoplasm, and is populated with nuclear pore complexes (NPCs) that regulate transport between these compartments. NPCs are multimeric complexes of 33 nucleoporins (Nups) in yeast, five of which contain glycine-leucine-phenylalanine-glycine (GLFG) rich repeats that maintain the passive diffusion barrier and mediate active transport through NPCs. In addition to being contiguous with the ER, the NE of *Saccharomyces cerevisiae* cells physically contacts the vacuole membrane at nuclear-vacuole junctions (NVJs). NVJ regions are regulated by several proteins including Nvj1 and Mdm1, and expand when cells are starved or cellular metabolism is altered. Using live cell fluorescence and electron microscopy, we present evidence that NE-vacuole contacts significantly increase when NPC assembly and nuclear envelope structure is perturbed, and that disabling NVJ function further disruptes NPC assembly. Mutant strains that specifically lack Nup116's GLFG domain (*nup116ΔGLFG* mutants) exhibit increased contacts between the vacuole membrane and NE, particularly at semi-permissive temperatures. Interestingly, expansion of these organelle contacts coincides with increases in NE herniations and GFP-Nic96 foci formation, indicative of NPC clustering and assembly defects. Since previous studies found that nuclear import by Kap121 is disrupted in *nup116ΔGLFG* cells, we examined GFP-Nic96 localization in temperature sensitive *kap121* mutants and found that GFP-Nic96 clusters to NE foci in a similar manner. Mutant *nup120Δ* and *nup133Δ* cells, both of which impede NPC assembly and cause significant NPC clustering, also display increased levels of vacuole-NE contacts, indicating this may be a general response to perturbed NPC function and/or assembly. *MDM1* and *NVJ1* were both deleted in *nup116ΔGLFG* mutants to formally test whether NE-vacuole interactions promote proper NPC assembly; *mdm1Δ njv1Δ nup116ΔGLFG* cells display decreased NE-vacuole contacts, increased GFP-Nic96 clustering, and synthetic growth defects. Interestingly, *mdm1Δ nvj1Δ* cells also display increased amounts of GFP-Nic96 foci and mild growth defects relative to wild type cells at higher temperatures.

Thus, we reveal a novel role for NE-vacuole contacts in proper NPC assembly, principally when assembly is already partially compromised in nucleoporin mutants. Further defining how these interorganelle contacts regulate NPC assembly and NE integrity will be especially important given that NPC-mediated transport and the Mdm1 ortholog Snx1 both regulate neurological diseases.

P508/B521

Structure-function an alysis of Heh1(LEM2) and Chm7 Suggests Role for Direct-PA-binding in Nuclear Envelope Surveillance.

D. J. Thaller[1], C. J. Marklew[2], B. Ciani[2], C. P. Lusk[1]; [1]Yale School of Medicine, New Haven, CT, [2]University of Sheffield, Sheffield, UNITED KINGDOM.

The endosomal sorting complexes required for transport (ESCRT) protein Chm7 has been implicated in a nuclear envelope surveillance pathway that directly monitors the cytosolic-exposure of the integral inner nuclear membrane protein Heh1 (LEM2) in budding yeast[1-3]. To establish additional genetic tools to functionally interrogate this pathway, we have performed a systematic deletion and point-mutation analysis of both Heh1 and Chm7. We have explored how these alleles impact Chm7 nuclear envelope targeting, "activation" and functional complementation in genetic backgrounds where *CHM7* and *HEH1* are essential. In so doing, we uncovered a previously unidentified role for a short hydrophobic stretch in Chm7 that confers specific binding to phosphatidic acid (PA). An analogous sequence in human CHMP7 binds non-specifically to lipids[4]. Consistent with the idea that PA-binding might be important for Chm7 function, the use of a gain-of-function chm7 protein results in the formation of a PA-rich domain at the inner nuclear membrane. Together, our data indicate that Chm7 binds to both Heh1 and PA-rich membranes and suggests a model where nuclear envelope surveillance might require changes to local membrane composition. The Nuclear Envelope Enriched Lipin Phosphatase Ctdnep1 Links Misregulation of Lipid Metabolism to Chromosome Instability in Dividing Cancer Cells.

H. Merta, **S. Bahmanyar, 06511**, J. Carrasquillo-Rodriguez, M. Deline, T. Vitale; Yale University, New Haven, CT.

Lipin1 is the key lipid metabolizing enzyme that controls ER lipid homeostasis. Lipin1 produces the precursors for triglycerides and membrane glycerophospholipids via its membrane binding domain while nuclear localized lipin1 inhibits the transcriptional activation of lipid synthesis genes. In the presence of nutrients, lipin1 is phosphorylated by mTORC1 and excluded from the nucleus. Here, we show in dividing cancer cells that CTDNEP1, a highly conserved integral membrane protein phosphatase, dephosphorylates lipin1 to counteract mTOR and in turn limit the production of glycerophospholipids in the ER and prevents chromosome instability. We demonstrate that CTDNEP1-deleted U2OS cells contain constitutively phosphorylated and reduced levels of lipin1 leading to elevated levels of

glycerophospholipids and triglycerides. In control cells, the majority of lipin1 is dephosphorylated upon inhibition of mTOR by Torin or in nutrient-poor conditions, yet lipin1 remains mostly phosphorylated in CTDNEP1-deleted cells under these conditions. Thus, CTDNEP1 dephosphorylates and stabilizes a pool of lipin by counteracting mTor in response to nutrient availability to maintain lipid homeostasis. Endogenous-GFP tagging showed that CTDNEP1 in U2 OS cells is enriched at the nuclear envelope (NE) suggesting that local regulation of lipin globally impacts ER lipid homeostasis. Increased glycerophospholipid synthesis in CTDNEP1-deleted cells causes expansion of ER membranes in mitosis leading to a faster rate of membrane wrapping around segregated chromosomes during nuclear formation and an increased incidence of micronuclei. Live imaging of CTDNEP1-deleted mitotic cells revealed ER membranes that invade the microtubule spindle region suggesting that excess ER membranes interfere with spindle assembly and chromosome segregation. Consistent with this, spindle morphology and nuclear reformation is severely disrupted after recovery from spindle microtubule destabilizing drugs. Together, these data demonstrate that NE-enriched CTDNEP1 activates a pool of lipin1 to maintain ER lipid homeostasis. The abundance of ER membranes, in turn, limit the rate of NE reformation to protect against chromosome missegregation and micronuclear formation. Thus, CTDNEP1 links mis-regulation of lipid metabolism to genome instability, two hallmarks of rapidly dividing cancer cells.

P510/B523

Atg39 Drives Nuclear Envelope Remodeling and Selectively Packages Components of the Inner Nuclear Membrane for Degradation by Autophagy.

S. Chandra, 06519, P. Mannino, D. Thaller, T. Melia, P. Lusk; Yale School of Medicine, New Haven, CT.

Selective autophagy uses cargo receptors to degrade superfluous or damaged subdomains on organelles. While we have a clear conceptual understanding of how cytoplasmic organelles are cleared by autophagy, how nuclear contents can be accessed by a primarily cytosolic machinery remains enigmatic. Here, we have recapitulated likely steps in a nucleophagy pathway by taking advantage of a recently-identified membrane-spanning nuclear cargo receptor in budding yeast, Atg39. Specifically, overproduction of Atg39 is sufficient to drive the formation of nuclear blebs that form independently of other autophagy proteins. Consistent with the conclusion that these blebs are functionally relevant, we observe a remarkable sequestration of some, but not other, inner nuclear membrane (INM) proteins suggesting that elements of nuclear-cargo selectivity are preserved. Interestingly, correlative light electron microscopy and tomography shows that the nuclear blebs contain consistently-sized vesicles likely derived from the INM, enclosed by an expanded outer nuclear membrane (ONM). This nuclear envelope remodeling could occur from the outside-in as we show using a split-GFP reporter system that, even when overexpressed, Atg39 accumulates specifically at the ONM. Thus, Atg39 targeting to the ONM and the formation of nuclear blebs with INM-cargo likely occurs through a physical coupling of both nuclear membranes. Consistent with this idea, we demonstrate that the formation of the nuclear blebs depends on the presence of the Atg39 lumenal domain, which is highly suggestive of a translumenal interaction with the INM. More systematic structure-function analyses of the lumenal domain of Atg39 supports the presence of unique ONM targeting and membrane-remodeling regions, the nature of which are currently being investigated within minimal in vitro membrane reconstitution platforms. Consistent with the idea that the nuclear blebs are ultimately engaged by an autophagosome, we demonstrate their clearance by autophagy after treatment with rapamycin. Thus, we have recapitulated the clearance of INM cargo by autophagy and are in a strong position to probe the

molecular requirements for each step in this pathway while fully assessing their functional significance using more traditional methods of nucleophagy-induction.

P511/B524

Golgi Unlinking during G2 Is Essential for Correct Spindle Formation and Cytokinesis.

F. Mascanzoni, I. Ayala, A. Luini, **A. Colanzi**; Institute of Cell Biology and Biochemistry (CNR), Naples, ITALY.

The Golgi complex of mammalian cells is composed of stacks connected by tubular bridges that form a continuous membranous system, which is also known as the Golgi ribbon. The Golgi ribbon undergoes a multistep disassembly process during G2/M transition. In particular, the cleavage of the ribbon into isolated stacks during G2 is required for entry into mitosis, indicating the existence of a 'Golgi mitotic checkpoint' able to monitor the correct mitotic inheritance of the organelle. The reason for which the Golgi unlinking is required for entry into mitosis is still not known. Here we demonstrate that forcing cells to enter into mitosis with an intact Golgi ribbon causes the formation of aberrant spindles and binucleated cells. Moreover, considering the functional relationship between the Golgi and centrosome, we tested if the presence of a centrosome was required for the Golgi-dependent G2 arrest. We found that the removal of centrosomes relieves the mitotic arrest induced by an intact Golgi. We hypothesize that an intact Golgi ribbon hampers centrosome repositioning during G2 and also induces altered subcellular localization of proteins involved in spindle formation. Our current work is aimed at a detailed understanding of the mechanisms underlying the functional relationships among Golgi unlinking, centrosome repositioning, spindle development and segregation of the genetic material.

Vac8 Differentially Regulate the Cvt and Pmn Pathways.

H. Kim; GIST graduate school, GWANGJU, KOREA, REPUBLIC OF.

Armadillo (ARM) repeat proteins constitute a large protein family with diverse and fundamental functions in all organisms, and armadillo repeat domains share high structural similarity. However, exactly how these structurally similar proteins can mediate diverse functions remains a long-standing question. Vac8 (vacuole related 8) is a multifunctional protein that plays pivotal roles in various autophagic pathways, including piecemeal microautophagy of the nucleus (PMN) and cytoplasm-to-vacuole targeting (Cvt) pathways in the budding yeast Saccharomyces cerevisiae. Vac8 comprises an H1 helix at the N terminus, followed by 12 armadillo repeats. Herein, we report the crystal structure of Vac8 bound to Atg13, a key component of autophagic machinery. The 70-Å extended loop of Atg13 binds to the ARM domain of Vac8 in an antiparallel manner. Structural, biochemical, and in vivo experiments demonstrated that the H1 helix of Vac8 intramolecularly associates with the first ARM and regulates its self-association, which is crucial for Cvt and PMN pathways. The structure of H1 helix-deleted Vac8 complexed with Atg13 reveals that Vac8[Δ19-33]-Atg13 forms a heterotetramer and adopts an extended superhelical structure exclusively employed in the Cvt pathway. Most importantly, comparison of Vac8-Nvj1 and Vac8-Atg13 provides a molecular understanding of how a single ARM domain protein adopts different quaternary structures depending on its associated proteins to differentially regulate 2 closely related but distinct cellular pathways.

P513/B526

CDK1 Controls ESCRT-III-dependent Nuclear Envelope Regeneration during Mitotic Exit.

C. Stoten[1,2], A. Gatta[1,2], Y. Olmos[1,2,3], J. G. Carlton[1,2]; [1]King's College London, London, UNITED KINGDOM, [2]The Francis Crick Institute, London, UNITED KINGDOM, [3]Universidad Complutense de Madrid, Madrid, SPAIN.

Through the process of annular fusion, the Endosomal Sorting Complex Required for Transport-III (ESCRT-III) machinery has emerged as a key player in the regeneration of a sealed nuclear envelope during mitotic exit, and in the repair of this organelle during interphase rupture. ESCRT-III polymerisation at the nuclear envelope occurs transiently during mitotic exit and CHMP7, an ER-localised ESCRT-II/ESCRT-III hybrid protein, initiates this process in a manner dependent upon the INM protein LEM2. Nucleocytoplasmic transport mechanisms act to separate LEM2 and CHMP7 during interphase, however, it is unclear how CHMP7 assembly is suppressed in mitosis when NE and ER identities are mixed. Further, the integration of ESCRT-III-dependent nuclear envelope sealing with classical cell-cycle control programmes, and mechanisms to ensure correct spatio-temporal assembly of ESCRT-III during mitotic exit are currently unclear. Here, we examine phosphorylation dynamics of CHMP7 during mitotic exit and identify CDK1 phosphorylation as a regulator of ESCRT-III activity for proper nuclear envelope regeneration.

P514/B527

Helical Folding of a Hydrophobic Stretch in CHMP7 Mediates Its Targeting to Membranes with Phosphatidic Acid.

A. Gatta[1,2], J. Carlton[1,2]; [1]King's College London, London, UNITED KINGDOM, [2]The Francis Crick Institute, London, UNITED KINGDOM.

The Endosomal Sorting Complex Required for Transport machinery is an ancient, evolutionarily conserved, multi-subunit complex that is deployed by cells to perform a diverse collection of physiological and pathophysiological processes. The membrane remodeling outcome of the ESCRT activity is mainly operated by ESCRT-III proteins which, among other functions, are involved in sealing of membrane fenestrations at several sites, including the nuclear envelope. CHMP7 is an ESCRT-II/ESCRT-III hybrid protein that transiently localizes to the resealing nuclear envelope during exit from mitosis. We have previously described an endoplasmic reticulum binding domain in CHMP7's N-terminus, in the absence of which ESCRT-III cannot subsequently assemble at the reforming nuclear envelope. However, the structural basis of membrane binding remained unclear. Here we applied co-sedimentation experiments with the recombinant protein and liposomes of different lipid composition and size to show that CHMP7's membrane binding increases upon exposure to phosphatidic acid, but it is neither affected by charged lipids nor different degrees of positive membrane curvature. Furthermore, we studied protein-lipid interactions with circular dichroism spectroscopy to reveal that interaction with phosphatidic acid causes an increase in helical content in the recombinant protein that can be traced to the hydrophobic stretch in the first winged helix domain of the ESCRT-II-like N-terminus. These data suggest that CHMP7 targeting to membranes might be dependent on the recognition of liquid disordered lipid phases in *vitro* that is reflected in the localization to areas with packing defects or negative curvature in the cell. Further structural and biophysical characterization of the membrane-bound CHMP7 will clarify the architectural details of its ER membrane targeting as well as the interplay between ESCRT-II and ESCRT-III membrane binding features.

Mitochondrial Dynamics and Morphology

P515/B528

Phosphorylation of Mitofusin GTPase Domain Regulates Fusion Activity.

B. Whitley, N. Samanas, **S. Hoppins**; University of Washington, Seattle, WA.

Mitochondrial structure is determined by dynamic processes including fusion, division and transport. Changes in mitochondrial structure evoke changes in mitochondrial function. To couple mitochondrial function to changes in cellular physiology, mitochondrial dynamics are regulated in response to different cellular signals. Mitochondrial fusion is mediated by large GTPases of the dynamin-related protein (DRP) family. In vertebrates, two isoforms of mitofusin, Mfn1 and Mfn2, are required for outer membrane fusion. To investigate the mechanism of mitofusin activity and its regulation in cells, we set out to identify and characterize novel post-translational modifications of Mfn1. In mass spectrometry analysis of Mfn1, we identified a modified peptide from a loop in the GTPase domain with a single conserved serine that is phosphorylated at steady state. To understand how phosphorylation might alter mitofusin activity, we have characterized the Mfn1 phosphoblocking (S-A) and phosphomimicking (S-E) variant proteins in vitro and in cells. Our data indicate that the phosphoblocking variant has wild type function while the substitution of glutamic acid at this position alters protein function. Using a minimal GTPase domain construct of Mfn1, we demonstrate that intrinsic enzyme activity is not altered by substitution of glutamic acid. Interestingly, our reconstituted mitochondrial fusion assay revealed that mitochondria with the phosphomimicking variant had severely diminished fusion activity compared to controls. To determine the basis of this impaired activity, we assessed two forms of nucleotide-dependent assembly. Consistent with diminished fusion activity, nucleotide dependent self-assembly of higher order oligomers and formation of a trans complex were both significantly impaired for the phosphomimicking variant. Therefore, this loop plays a critical role in mitofusin function. Together, our data are consistent with a model where phosphorylation of this residue decreases fusion activity by impairing mitofusin assembly.

P516/B529

Membrane Phospholipid Composition Directly Influences Mitochondrial Dynamics.

J. G. Pemberton, Y. Kim, M. Korzeniowski, J. E. Heuser, T. Balla; National Institute of Child Health and Human Development, NIH, Bethesda, MD.

The coordinated fusion and fission of mitochondria has been shown to be critical for maintaining the functional integrity of this essential organelle and several human diseases are associated with defective mitochondrial dynamics; including structural abnormalities that manifest during the progression of cancers, diabetes, and severe neurodegenerative disorders. Although a growing number of proteins have been identified as important regulators of mitochondrial morphology, the direct role of membrane lipids during the fusion and fission processes have not been assessed experimentally. To address these shortcomings, we devised a protein-engineering platform that would allow for the acute remodeling of defined classes of phospholipids within the outer mitochondrial membrane (OMM) of intact cells. For this, we used a modified bacterial phosphatidylinositol (PtdIns)-specific phospholipase C (bacPIPLC) scaffold to selectively hydrolyze the headgroup from PtdIns and generate a membrane-embedded diacylglycerol (DAG) backbone. Spatial restriction of bacPI-PLC activity was achieved by attaching the rapamycin-inducible FK506-binding protein (FKBP) dimerization module (FKBP-PIPLC) and co-expressing

a validated OMM-targeting sequence labeled with the FKBP-rapamycin binding domain (AKAP-FRB). Recruitment of the FKBP-PIPLC to the OMM not only caused the expected local accumulation of DAG, which we visualized using a high-affinity biosensor, but it also initiated the rapid and uniform fragmentation of the mitochondria. As important controls for these studies, targeting of a catalytically-inactive variant of the FKBP-PIPLC to the OMM failed to induce fragmentation of the mitochondria. The dramatic structural effects induced by the active FKBP-PIPLC also failed to alter the OMM potential or lumenal Ca^{2+} concentration; suggesting that the changes observed are not due to gross insults to the integrity of the OMM. Results using electron microscopy reinforce these data as well as revealed marked vesiculation of the inner mitochondrial membrane (IMM) as well as an associated loss of cristae that occurs just minutes after tethering the FKBP-PIPLC to the OMM. These phenotypic changes are reminiscent of the chronic alterations to IMM morphology that are observed in cells lacking protein machineries involved in coordinating IMM dynamics or that facilitate non-vesicular lipid transport between the OMM and IMM. Taken together, these findings highlight the unique opportunity afforded by this system to understand how rapid changes to the lipid composition of the OMM can be transmitted to the IMM as well as establish a direct relationship between lipid metabolism within the OMM and morphological changes that manifest in mitochondrial-associated diseases.

P517/B530

Ubl4A Is Critical for Mitochondrial Fusion Under Nutrition Deprivation through Arp2/3 Complex.

H. Zhang, Y. Zhao, J. Xiang; Illinois Institute of Technology, Chicago, IL.

Mitochondrial fusion and fission are dynamic processes regulated by the actin network. Under a nutrition starvation condition, mitochondrial fusion process is increased for energy conservation. We have previously shown that Ubl4A-deficient neonatal mice were sensitive to starvation stress during birth. The underlying mechanism is through a direct association of Ubl4A with actin-related protein Arp2/3 complex to synergize actin branching process. Here we found that mitochondria in the Ubl4A knockout newborn mouse livers were fragmented and lost integrity. Time-lapse imaging indicated that mitochondrial fusion process in the Ubl4A-deficient cells was significantly delayed under starvation. Immunostaining reveled that Ubl4A co-localized with the Arp2/3 complex on mitochondria. Interestingly, deficient in Ubl4A resulted in less Arp2/3 complex around mitochondria. Knockdown of the Arp2/3 complex in wild-type cells impaired mitochondrial fusion under nutrition deprivation. Consistently, put-back of the wild-type but not the Arp2/3-binding deficient mutant Ubl4A could rescue the starvation-induced mitochondrial elongation phenotype. These results suggest that Ubl4A-mediated Arp2/3-actin network is critical for mitochondrial fusion process under nutrition deprivation stress.

P518/B531

Understanding How Post-translational Modifications Regulate the Mitochondrial Fission Machinery in Glioblastoma.

E. O. Akinbiyi[1], B. L. Bauer[1], L. Abramowitz[2], J. A. Hanover[2], J. A. Mears[1]; [1]Case Western Reserve University, Cleveland, OH, [2]National Institutes of Health, Bethesda, MD.

Mitochondria are essential and dynamic organelles that maintain a delicate balance of division and fusion in response to cellular stimuli. These processes sustain mitochondrial health and function, and alterations to either fission or fusion are associated with a variety of diseases, including cancer. Glioblastoma (GBM) is an aggressive brain cancer that takes the lives of nearly 90% of patients within 5

years of diagnosis. Glioblastoma stem cells (GSCs) represent a subset of the tumor cells that can self-renew and propagate new tumors, which contributes to higher rates of recurrence. GSCs also are resistant to conventional GBM therapies, including chemotherapy and radiation. Recent studies have observed excessive mitochondrial fission in GSCs when compared to non-stem GBM cells. This finding may represent underlying bioenergetic changes, which lead to altered post-translational modifications (PTMs) of proteins in the mitochondrial fission machinery. Dynamin-related protein 1 (Drp1), the essential mediator of mammalian mitochondrial fission, is regulated by PTMs, such as phosphorylation and O-GlcNAcylation. In addition, PTMs on Drp1's partner proteins, such as mitochondrial fission factor (Mff), may also effect the recruitment of Drp1 to the mitochondria. We propose that O-GlcNAcylation of Drp1 is an activating modification that promotes Drp1 re-localization from the cytosol to the mitochondria resulting in increased mitochondrial fission. In addition, we are examining the phosphorylation status of Mff to identify synergistic changes that favor mitochondrial division. Overall, our goal is to characterize the impact of PTMs on the fission machinery to assess functional changes leading to altered mitochondrial dynamics in GSCs. In this way, we hope to identify potential therapeutic targets that alter PTMs in GSCs to prevent recurrence in GBM patients.

ALS/FTD Mutant CHCHD10 and CHCHD2/CHCHD10 Loss Trigger OPA1 Processing by OPA1 and Cardiomyopathy in *Vivo*.

D. Narendra, Y. Liu, X. Huang, D. Springer, S. Sekine; NINDS, Bethesda, MD.

Objective: Characterization of mitochondrial cristae and OPA1 processing in CHCHD2/10 DKO and mutant CHCHD10 KI mice. Introduction: Dominant mutations in the mitochondrial paralogs CHCHD2 and CHCHD10 were recently identified as causing Parkinson's disease and ALS/FTD/myopathy, respectively. Their mutation or loss has been associated with aberrant mitochondrial cristae structure in a variety of models; the mechanism, however, has been unclear. Additionally, the precise mechanism of mutant CHCHD2/CHCHD10 pathogenesis (toxic gain-of-function vs. dominant negative) and its relationship to the normal physiologic function of CHCHD2 and CHCHD10 has been unknown. Methods: analysis of cell lines and mouse heart, using transmission electron microscopy, super-resolution light microscopy, echocardiography, immunoblotting, and transcriptomics. Results: Here we report that fibroblasts from the first CHCHD2/CHCHD10 double knockout (DKO) mouse exhibit cristae abnormalities due to cleavage of the fusogenic long OPA1 isoforms by the stress-induced peptidase OMA1. OMA1 KO reciprocally altered the processing and distribution of CHCHD2/CHCHD10: intense CHCHD2/CHCHD10 foci formed in OMA1-deficient mitochondria with expanded inner membrane structures, and CHCHD2/CHCHD10 was degraded upon OMA1 activation. CHCHD10 mutation or CHCHD2/CHCHD10 knockout also caused OMA1 activation in *vivo*. Knock-in CHCHD10 S59L mice exhibited OPA1 cleavage by OMA1 coincident with development of cardiomyopathy and activation of the mitochondrial integrated stress response (mt-iSR); cardiomyopathy with OMA1 and mt-iSR activation were partially phenocopied in CHCHD2/CHCHD10 DKO mice. Summary: OPA1 cleavage by activated OMA1 is identified as a common response to mutant CHCHD10 and CHCHD2/CHCHD10 double knockout in cell culture and in *vivo* and is at least partially responsible for observed cristae abnormalities in these models. mt-iSR and development of cardiomyopathy are additionally phenocopied in CHCHD2/CHCHD10 DKO and mutant CHCHD10 mice. Conclusion: These findings link the physiologic role of CHCHD2/CHCHD10 in maintaining L-OPA1 stability to the pathogenesis of mutant CHCHD10. Additionally, they identify OMA1 as a

potential therapeutic target in CHCHD2/CHCHD10-related disease. Acknowledgement: This research was supported (in part) by the Intramural Research Program of the NIH, NINDS

MCL-1 Is an Essential Modulator of Mitochondrial Dynamics in Stem Cells and Cardiomyocytes.

M. L. Rasmussen[1], N. Taneja[1], L. Shi[1], A. C. Neininger[1], K. E. Beckermann[2], J. C. Rathmell[2], D. T. Burnette[1], V. Gama[1]; [1]Vanderbilt University, Nashville, TN, [2]Vanderbilt University Medical Center, Nashville, TN.

MCL-1 (myeloid cell leukemia-1) has been well-characterized as an anti-apoptotic protein. Recent studies from our laboratory also implicate MCL-1 as a novel modulator of mitochondrial dynamics and metabolism at both the outer mitochondrial membrane and the matrix. My studies show that MCL-1 downregulation in stem cells induces dramatic changes to the mitochondrial network, as well as the loss of the key pluripotency transcription factors, NANOG and OCT4. Mechanistically, this change in mitochondrial network morphology is due, at least in part, to MCL-1 interaction with DRP-1 (dynamin-related protein 1) and OPA1 (optic atrophy 1), two GTPases responsible for regulating mitochondrial dynamics. Depletion of MCL-1 affected the rates of mitochondrial fission and caused a shift in the metabolic profile of stem cells, pointing to MCL-1 as a potential mediator of mitochondrial dynamics and metabolism. To decipher the molecular mechanism for MCL-1 regulation of DRP-1 and OPA1, we are currently performing structure-function analyses coupled with high resolution imaging to examine the effects of disrupting these protein interactions. We hypothesize that MCL-1 is essential for mitochondrial homeostasis by modulating mitochondrial morphology and function, independently of its canonical role in apoptosis. Recently discovered small molecule inhibitors of MCL-1 are being tested as chemotherapeutic agents for MCL-1-sensitive tumors. Our preliminary studies point to a conserved role of MCL-1 in maintaining mitochondrial integrity in human induced pluripotent stem cell-derived cardiomyocytes (iPSC-CMs). Inhibition of MCL-1 in iPSC-CMs has significant effects on mitochondrial morphology and myofibril assembly, even in the absence of caspase activation. Functionally, MCL-1 inhibition caused significant defects in cardiomyocyte contractility and beating rates. Elucidating these alternative functions of MCL-1 in human cells will be crucial to reveal potential adverse effects caused by MCL-1 inhibitors currently being tested in the clinic. Our studies aim to uncover the mechanisms by which MCL-1 and the BCL-2 family of proteins control mitochondrial dynamics and metabolism during reprogramming and differentiation.

α-synuclein Has Distinct in *Vivo* Roles in Mitochondrial Dynamics and Mitochondrial Homeostasis.

S. Gunawardena, T. J. Krzystek, R. Banerjee, L. Thurston, J. Q. Huang, K. Swinter; SUNY-Buffalo, Buffalo, NY.

The balance between fission via dynamin-related protein (DRP1) and fusion via mitofusin (MFN), which occur in concert to mitochondrial motility, is critical for mitochondrial health in axons. Defects in fission-fusion and disruption of mitochondrial transport within axons have been linked to mitochondrial dysfunction and neurodegeneration. While α-synuclein (α-syn) has been proposed to influence mitochondrial dynamics within axons, the mechanistic details of how α-syn effects mitochondrial homeostasis remains unknown. We found that excess α-syn causes mitochondrial fragmentation, similar to excess DRP1, but in contrast to excess MFN2, which caused elongated mitochondria. Intriguingly, excess or depletion of DRP1 rescued α-syn-mediated mitochondrial fragmentation, while excess MFN

had no effect. Deletion of the acidic C-terminal domain of α-syn (α-syn1-120) which is thought to hinder membrane binding, or the NAC domain (α-synΔNAC) which is thought to promote self-aggregation did not affect α-syn-mediated mitochondrial fragmentation. Further, α-syn-mediated mitochondrial fragments were oxidized as assayed by the in *vivo* oxidation marker MitoTimer. However, α-syn 1-120-mediated fragmented mitochondria were healthier. Intriguingly, while α-syn-mediated oxidized mitochondrial fragments showed biased retrograde motility, α-syn 1-120-mediated healthy mitochondrial fragments did not. Together our observations suggest that mitochondrial size is independent of mitochondrial health in *vivo*, and demonstrates that the N and C-terminal regions of α-syn have novel in *vivo* roles during mitochondrial fission and oxidation. Therefore, our findings provide a novel physiological role for α-syn during mitochondrial homeostasis, and highlight a common pathological mechanism for targeted therapeutics early before neuronal loss or clinical manifestation of Parkinson's disease.

P522/B535

Pink1 Promotes Mitochondrial Fission and Its Essential for Porcine Embryonic Development.

Y. Niu, X. Cui; Chungbuk National University, Cheongju, KOREA, REPUBLIC OF.

Phosphatase and tensin homolog (PTEN)-induced kinase 1 (PINK1) selectively locates to the outer membrane of impaired mitochondria and promotes their autophagy. On the other hand, PINK1 regulates mitochondrial morphology by interacting with mitochondrial fission and fusion components, shift mitochondrial fusion/fission balance towards more fission. In mammalian, the oocytes and early embryos has approximately 2×10^5 mitochondria, at least one or two orders of magnitude more than somatic cells, but few studies focus on the mitochondrial dynamics during preimplantation embryo development. To investigate whether PINK1 are required for mitochondria dynamics in porcine preimplantation embryos, gene knockdown and inhibitors were engaged in the present study, and mitochondrial dynamics were observed by transmission electron microscope. The results showed that knockdown of PINK1 significantly impaired blastocyst formation and quality. In addition, TEM analysis revealed that knockdown of PINK1 induced mitochondrial elongation and swollen. Mitochondrial DNA (mtDNA) copy number was reduced after PINK1 knockdown. Elongated mitochondrial induced by PINK1 knockdown further caused mitochondrial dysfunction, oxidative stress and ATP deficiency. Finally, both of the autophagy and apoptosis were significantly increase after mitochondrial dysfunction. However, over expression of Drp1 prevented mitochondrial elongation and embryo development impairments induced by PINK1 knockdown. In conclusion, these data suggest that PINK1 promotes mitochondrial fission in porcine preimplantation embryos.

Mtfr2 Is Required for Mitochondrial Fission and Accurate Chromosome Segregation.

Y. Luo, S. Liu; the University of Toledo, Toledo, OH.

Mitochondria change shapes through the combined action of fusion and fission. The crosstalk between mitochondria dynamics and cell division has drawn lots of attention in recent years. In this study, we characterized MTFR2 and explored its role in mitochondrial fission and cell division.MTFR2 is located on the outer membrane of mitochondria by both super-resolution and laser-scanning confocal microscopy Domain-mapping showed the first 50 amino acids of MTFR2 was sufficient for its mitochondrial

targeting. Overexpressing MTFR2 in Hela cells promoted DRP1 dependent mitochondrial hyper-fission even in G1/S arrested cells. DRP1 is a dynamin-related large GTPase whose polymerization is essential for mitochondrial fission. On the other hand, depleting MTFR2 through RNAi or CRISPR-Cas9 resulted in longer and interconnected mitochondrial. Though the expression level, as well as the DRP1 localization, were not altered after MTFR2 depletion, immunoprecipitation showed MTFR2 depletion affected the polymerization of DRP1, but MTFR2 and DRP1 had no direct interaction.MTFR2 is the only known mitochondrial fusion/fission factor that is co-transcribed with core centromere/kinetochore components. MTFR2 is phosphorylated during mitosis, similar to the canonical mitochondrial fission regulating GTPase DRP1. Time-lapse live-cell imaging demonstrated MTFR2 depletion extended the average duration from nuclear envelope breakdown to anaphase onset (59min vs 141min). Expressing wild type MTFR2 but not MTFR2 mutants found in cancer samples in the knockout cells rescued the defect, suggesting MTFR2 is important for normal cell division. Interestingly, it was also found that chromosomal condensation was compromised in MTFR2 knockout cells.In conclusion, MTFR2 functions to regulate proper mitochondrial fission and chromosomal segregation. More detailed mechanistic studies on MTFR2 will contribute to further understanding of the function of mitochondria and mitochondrial proteins in cell division.

Using Single-Molecule Localization Microscopy to Study Protein Organization and Function at a Molecular Level to Gain a Better Understanding of Many Biological Phenomena.

G. Schneider; ONI, Menlo Park, CA.

Studying protein organization and function at molecular level is a major technical challenge that limits our understanding from both a diagnostic and treatment perspective. Single-molecule localization microscopy (SMLM) is a Nobel Prize winning technique that allows quantitative imaging below the diffraction limit and can be applied to significantly improve our understanding of many biological phenomena. ONI has created the world's first desktop super-resolution microscope, the Nanoimager, for imaging single molecules. The Nanoimager is a compact and state-of-the-art microscope, offering quantitative analysis for localization-based imaging (dSTORM and PALM), single-particle tracking and single-molecule FRET. With the addition of SIM/confocal imaging capabilities, the Nanoimager provides a versatile imaging platform with unrivalled stability and flexibility to work on a lab bench.The data presented was acquired using two-color, super-resolution imaging of the mitochondrial markers, TOM20 and HSP60, to clearly resolve the sub-mitochondrial compartment and reveal their spatial organization at 20 nm resolution. Moreover, optical sectioning using Structured Illumination Microscopy (SIM) in three colors showed the co-localization of mtDNA-associated proteins along the mitochondrial network. Finally, live-cell time-lapse imaging and automated particle tracking analysis was used to investigate Drp1 dynamics and interactions with the mitochondria. This presentation provides evidence of the use of SMLM imaging as a powerful tool for rapid and multiplexed mitochondria characterization in combination with unique structural insight. They have demonstrated the wide-ranging applicability of the Nanoimager in different biological applications encompassing the field of immunology, neurobiology, cell biology and cancer.

Opa-1 Deficiency Promotes Muscle Atrophy through Upregulating Er-Mito Contacts and Autophagy.

B. P. Kirk[1], M. Mungai[1], I. Hicsasmaz[1], H. Le[1], Y. Li[1], L. J. Kazma[1], S. Bacevac[1], A. Dewan[1], K. Tani[1], J. Samuel[1], A. Hinton, Jr.[1], P. Katti[2], B. Glancy[2], R. O. Pereira[1], D. Abel[1]; [1]University of Iowa, Iowa City, IA, [2]National Institutes of Health, Bethesda, MD.

Type 2 Diabetes (T2DM) in some patients has been shown to have dysregulated Mitochondria Associated Membranes (MAMs) and decreased muscle mass. MAMs are enriched with specific proteins and lipids that aid in specialized structural rearrangements such as the formation of autophagosomes. Decreased optic atrophy protein-1 (OPA-1) in skeletal muscle has been reported in both murine and human T2DM models. Loss of OPA-1 in skeletal muscle has been observed to cause muscle atrophy and increase mitochondria associated membrane-tethering protein Mitofusin-2 (MFN-2). The Framingham Offspring Study has shown that high plasma branch amino acids (BCAAs) concentrations were linked to an increased risk of T2DM and BCAAs have been observed to regulate autophagosome recruitment through interactions with mammalian target of rapamycin complex (mTORC1). Therefore, we hypothesized that OPA-1 deficiency induces catabolism of skeletal muscle resulting in an increase in BCAAs that recruit autophagosomes to the MAM space (MAI). To investigate the role of OPA-1 on MAI, studies were performed in OPA-1 deficient mice and OPA-1 ablated skeletal muscle cells. The ablation of OPA-1 in skeletal muscle showed a decrease in soleus, gastrocnemius, quadriceps, and tibialis anterior muscle weight. Notably, loss of OPA-1 in gastrocnemius muscle showed an increase in the following MAM proteins that are important for MAI tethering which include: MFN-1, MFN-2, and PACS2. Loss of OPA-1 also increased the MAM autophagosomal recruiting protein, ATG5. qPCR analysis after the deletion of OPA-1 in 40-week skeletal muscle displayed an increase in MFN-1, MFN-2, LC3B, ATG7, and ATG5 transcripts, while p62 transcripts were shown to decrease. Primary myoblast and myotubes were generated by isolating satellite cells from OPA-1 floxed mice, differentiated, and subsequently the deletion of OPA1 by infecting the cells with adenoviral Cre recombinase. Ablation of OPA-1 in myotubes increased the following MERC proteins: MFN-1, MFN-2, and PACS2. TEM an alysis of OPA-1 deficient skeletal muscle and myotubes had an increase in MAI and lysosome structures. An alysis of amino acid metabolite peak intensities heat map indicated that an increase in Isoleucine, Leucine, and Valine occurred after the deletion of OPA-1 in skeletal muscle. This data suggests that loss of OPA-1 increased MAIs, which may lead to decreased muscle mass and that amino acids may contribute to the recruitment and formation of autophagosomes.

P526/B539

Opa-1 Deficiency in Skeletal Muscle Increases Mitochondria-er Contact Formation through an Atf-4 Dependent Mechanism.

A. O. Hinton, Jr.[1], P. Katti[2], M. Mungai[1], B. P. Kirk[1], B. Glancy[2], R. Pereira[1], D. Abel[1]; [1]University of Iowa, Iowa City, IA, [2]National Institutes of Health, Bethesda, MD.

Defective mitochondria-associated membranes (MAMs) or mitochondria and endoplasmic reticulum (ER) contact sites (MERCs), has been associated with insulin Resistant Type 2 Diabetes Mellitus (T2D). MERCs are enriched with specific proteins and lipids that are believed to mediate inter-organellar communication such as calcium and lipid transfer, autophagosome formation, regulation of mitochondrial morphology, and apoptosis. Previously, we demonstrated that OPA-1 deficiency in skeletal muscle induces ER stress, which correlated with upregulation of Mitofusin-2 (MFN-2), which is a

known tethering protein in MERCs. Therefore, we hypothesized that OPA1-induced mitochondrial stress results in narrowing of MERC distance through the upregulation of tethering proteins. To test this hypothesis, we surveyed for several MERCs proteins in OPA1-deficient skeletal muscle samples and primary myoblasts. Primary myoblasts were generated by isolating satellite cells from OPA-1 floxed mice and subsequently deleting OPA1 by infecting the cells with adenoviral Cre recombinase. Ablation of OPA-1 in myoblasts increased the following MERC proteins: MFN-1, MFN-2, BIP. Similarly, loss of OPA-1 in skeletal muscle increased MFN-1, MFN-2, PACS-2, GRP75, BIP, and IP3R. qPCR was done to assess gene expression, ER stress genes (ATF4, ATF6, BIP, CHOP) and MERC genes (IP3R3, GRP75, VDAC3, MFN-2) increased after the deletion of OPA-1 in myoblasts and skeletal muscle. An alysis of proximity ligation assay revealed that MFN-1 and MFN-2 interactions are increased in OPA-1 deficient cells and that VDAC and IP3R and MFN-1 and MFN-2 interactions were increased in OPA-1 deficient skeletal muscle. TEM an alysis of OPA-1 deficient myoblasts and soleus skeletal muscle confirmed an increase in the number of MERCs and a reduced distance between ER and Mitochondria. TUDAC treatment decreased ER stress Gene Expression (ATF4 and CHOP) and MERC gene expression (IP3R3, GRP75, VDAC3, MFN-2) in OPA-1 deficient skeletal muscle compared to control. Promoter analysis of a CHIPseq data set revealed that ATF4 and CHOP bind to the promoters of MERCs that are upregulated in OPA-1 deficient samples. Collectively, these data suggest that loss of OPA-1 in muscle cells results in the induction of MERC proteins, which correlates with increased MERCS formation. Increased MERCs may represent a compensatory mechanism in response to mitochondrial stress that is precipitated by OPA1 deficiency.

P527/B540

Investigating the Mechanism and Regulation of Mitochondria-dependent Dynein an choring.

H. L. An derson, L. L. Lackner; Northwestern University, Evanston, IL.

The distribution of organelles is closely linked to their function and inheritance in cells. One protein in budding yeast, Num1, serves to position and aid in the inheritance of both mitochondria and the nucleus. Specifically, Num1 anchors mitochondria as well as dynein to the cell cortex, and this anchoring activity is required for proper mitochondrial distribution and dynein-mediated nuclear inheritance. We have previously shown that mitochondria drive the assembly of Num1 clusters, which then serve as cortical attachment sites for dynein. Using a synthetic clustering system to bypass the requirement of mitochondria for Num1 cluster formation, we were able to create two populations of Num1 clusters, mitochondria-associated and non-associated clusters. We found that dynein was preferentially anchored to mitochondria-associated clusters. We are now using a structure-function approach to dissect the mechanism and regulation of this mitochondria-dependent dynein anchoring. Using a series of Num1 truncations in our synthetic clustering system, we have identified a region of Num1 that is important for the mitochondria-dependent association of dynein with Num1. In the absence of this region, we find a significant increase in cortical dynein anchoring at Num1 clusters that are not associated with mitochondria. These data suggest that this region of Num1 negatively regulates cortical dynein anchoring. Consistently, we find that in our synthetically clustered system, cells lacking this region of Num1 exhibit increased dynein activity. Based on these data, we hypothesize that this identified region of Num1 promotes an arrangement of the protein within a cluster that favors dynein anchoring in the presence of mitochondria and, consequently ensures dynein anchoring occurs after mitochondrial inheritance. The spatiotemporal integration of mitochondrial and nuclear positioning pathways likely contributes to the regulated order of organelle inheritance during the cell cycle.

P528/B541

Regulated Expression of the Autophagy Receptor NIX Initiates Mitochondrial Fission Via DRP1 to Drive Proper Epidermal Differentiation.

C. L. Simpson, E. L. F. Holzbaur; University of Pennsylvania, Philadelphia, PA.

Epidermal keratinocytes degrade all intracellular organelles during a specialized process of terminal differentiation to form compact cornified layers that provide a protective outer barrier for the body. To understand how keratinocytes initiate this process of programmed organelle break-down, we coupled live confocal microscopy with organotypic human epidermis to visualize single-organelle dynamics in the stratified differentiated tissue. In the uppermost epidermal layers, we found that mitochondria transform from interconnected tubules to spherical fragments, suggesting an up-regulation of fission. Coincident with this morphological change, upper layer keratinocytes in both organotypic cultures and in normal human skin accumulate high levels of NIX, a membrane-tethered mitophagy receptor known to be induced by hypoxia. We hypothesized that increased levels of NIX could initiate mitochondrial fission and mitophagy during terminal keratinocyte differentiation. In agreement with this, ectopic expression of NIX in undifferentiated keratinocytes was sufficient to induce mitochondrial fragmentation and drove premature differentiation of organotypic epidermis. Toward a mechanism, we found that NIX enhanced mitochondrial localization of FIS1, a receptor for the membrane fission GTPase dynamin-related protein 1 (DRP1). Accordingly, NIX also enhanced recruitment of DRP1 to the mitochondrial outer membrane and increased DRP1 levels in mitochondrial fractions of cell lysates. Moreover, using a dominant-negative DRP1 (K38A), we confirmed that NIX required DRP1 activity to induce mitochondrial fragmentation. Finally, we found that expression of DRP1-K38A or treatment with the DRP1 inhibitor Mdivi-1 impaired mitochondrial fragmentation and resulted in aberrant morphogenesis of organotypic epidermis, indicating DRP1-dependent mitochondrial fission is essential for epidermal tissue differentiation. Based on our findings, we propose a model in which NIX expression is up-regulated in the outer layers of the epidermis to properly initiate mitochondrial fragmentation via DRP1 to initiate terminal differentiation and epidermal barrier formation.

P529/B542

Two Forms of Opa1 Coordinate to Induce Mitochondrial Inner Membrane Fusion.

Y. Ge[1], S. Boopathy[1], X. Shi[2], A. Smith[3], L. H. Chao[1]; [1]The Massachusetts General Hospital, Boston, MA, [2]Case Western Reserve University, Cleveland, OH, [3]University of Akron, Akron, OH.

Mitochondrial membrane dynamics is a cellular rheostat that relates organelle morphology and metabolic function. Using an in *vitro* reconstitution system, we describe a mechanism for how mitochondrial inner-membrane fusion is regulated by the ratio of two forms of Opa1. We found that the long-form of Opa1 (l-Opa1) is sufficient for membrane docking, hemifusion and basal levels of content release. However, stoichiometric levels of the processed, short form of Opa1 (s-Opa1) work together with l-Opa1 to mediate efficient and fast membrane pore opening. Additionally, we found that excess levels of s-Opa1 inhibit fusion activity, as seen in conditions of abnormal cellular proteostasis. These observations describe a tunable mechanism for gating membrane fusion.

P530/B543

Spatial Organization of Mitochondrial Inner Membrane Subdomains.

K. Subramanian[1], S. Barger[2], A. Guna[3], J. Nunnari[1]; [1]University of California, Davis, Davis, CA, [2]SUNY Upstate Medical University, Syracuse, NY, [3]MRC Laboratory of Molecular Biology, Cambridge, UNITED KINGDOM.

The mitochondrial inner membrane is an essential platform to perform and integrate key cellular pathways ranging from oxidative phosphorylation to mitochondrial genome replication and expression. As such, the inner membrane is protein-dense and highly organized into at least three morphologically and compositionally distinct domains: cristae, cristae junctions, and boundary regions. Based on an analysis of a small fraction of the inner membrane proteome, it is thought that the electron transport and respiratory complex assembly machinery are distinctively localized to cristae while in contrast, solute transporters and protein import machinery are enriched in boundary regions. To gain insight into the mechanisms underlying the domain sorting of inner membrane proteins, we systematically determined the subdomain localization of a majority of inner membrane-associated proteins in budding yeast. We resolved the domain localization of fluorescently-tagged versions of inner membrane proteins by light microscopy by expanding the diameter of mitochondria in vivo using a conditional mutation of MDM12, which encodes an essential component of the ER-mitochondria encounter structure. Our results indicate that a majority of GFP-tagged inner membrane proteins localized to cristae, as opposed to boundary regions, and a majority of respiratory and protein import machinery localized to cristae and boundary regions, respectively. However, there were a number of exceptions including a cristae-localized solute transporter, Yea2, and boundary-localized respiratory assembly protein, Rcf2. Our data suggest a simple model in which boundary and cristae regions are generated by retention of a majority of proteins in cristae.

P531/B544

3D-SIM/FIB-SEM Allows Correlation of Mitochondrial Membrane Potential and Nucleoid Distribution with Mitochondrial Ultrastructure.

A. S. Moore, D. P. Hoffman, G. Shtengel, E. Betzig, H. Hess, J. Lippincott-Schwartz; Howard Hughes Medical Institute, Ashburn, VA.

Mitochondria are double-membrane organelles that carry out numerous cellular functions including oxidative phosphorylation, calcium buffering, and lipid synthesis. Mammalian cells can contain hundreds or even thousands of mitochondria that organize into a dynamic pleiomorphic network. Within this network, individual mitochondria are both structurally and functionally diverse. Understanding and better characterizing mitochondria heterogeneity within a single cell is a major ongoing effort that has been hampered by the lack of methods available to correlate mitochondria functional state with their morphology and ultrastructure. Here we describe a pipeline that enables the correlation of mitochondrial membrane potential obtained by cryogenic superresolution microscopy with ultrastructural information obtained by 3D electron microscopy (EM). Specifically, we plated U2OS cells on sapphire coverslips and incubated cells with TMRM, a cationic dye that can be used to estimate mitochondrial membrane potential, and SybrGreen, a DNA dye that can selectively label mtDNA nucleoids. The cells were then high pressure frozen and imaged by cryogenic 3D-Structured Illumination Microscopy (SIM). Whereas TMRM and SybrGreen are typically lost from mitochondria upon conventional chemical fixation, we found that both dyes retained their mitochondrial localization in the

vitreously frozen cells. Next, cells were processed for EM by freeze substitution, heavy metal staining, and embedding in Eponate 12 resin. Finally, cells were imaged by Focused Ion Beam Scanning EM (FIB-SEM) with isotropic 8 nm voxels and the resulting EM stack was manually aligned with the 3D-SIM data using the BigWarp ImageJ plugin. In the aligned data, we observed that TMRM robustly correlated with the position of mitochondria cristae, while SybrGreen-marked nucleoids appeared to instead localize to regions with decreased cristae density. Moving forward, we plan to use this correlative approach to explore how mitochondrial membrane potential varies both across and within mitochondria, whether membrane potential is locally influenced by mitochondria-organelle contacts, and finally how mtDNA nucleoid number scales to mitochondria volume.

P532/B545

Patient Mutation in CHCHD10 Causes Myopathy and Oma1-dependent Mitochondrial Fragmentation.

M. Shammas[1], X. Huang[1], Y. Liu[1], D. Springer[2], D. Nguyen[1], D. Narendra[1]; [1]NINDS, Bethesda, MD, [2]NHLBI, Bethesda, MD.

The paralogous mitochondrial proteins CHCHD2 and CHCHD10 have been recently identified as autosomal dominant causes of Parkinson's disease and ALS/FTD (as well as myopathy), respectively, when mutated. Interestingly, these mutations also lead to mitochondrial DNA (mtDNA) instability. The function of these proteins, as well as the mechanism by which their mutations lead to disease, remain unknown. The currently prevailing model of pathogenicity involves mutations in the proteins leading to protein aggregation and maladaptive activation of the mitochondrial integrated stress response, ultimately leading to cell death (the toxic gain-of-function model). However, recent work by our lab shows that the same mitochondrial stress response pathway is activated by knocking out both CHCHD2 and CHCHD10. Additionally, the identification of a new pathogenic mutation (G58R) whereby a hydrophobic amino acid is substituted by a hydrophilic one (thus decreasing propensity to aggregate) also does not fit within the aggregation model. Recent work by our lab also identified cleavage (and inactivation) of the mitochondrial shaping protein OPA1 by the peptidase OMA1 in CHCHD10 KI and CHCHD2/CHCHD10 KO models. We have developed a KI mouse model of the G58R mutation, which, in humans, causes a cardiomyopathy. We show that the G58R mouse recapitulates the cardiomyopathy phenotype more profoundly than the previously described S59L KI model. Muscle wasting is evident from the decreased weights of the G58R mouse compared to WT. Behaviorally, the G58R mouse displays significant motor and balance impairment when assessed for grip strength, rotarod balance and time until fatigue on a treadmill. We see OMA1 activation and cleavage of OPA1 in tissue obtained from the G58R mouse. Additionally, we will assess for CHCHD10 aggregation and analyze mtDNA for deletions and copy number depletion. In summary, we describe in this study a new mouse model for myopathy that provides insights into alternative mechanisms underlying the pathogenesis of CHCHD2/CHCHD10 mutations.

Mitochondrial Contacts with Other Organelles

Human Beta-glucosidase 2 (GBA2) Contains a Functional Mitochondrial Targeting Domain.

A. C. Van Der Spoel, S. Sultana, J. Stewart; Dalhousie University, Halifax, NS, CANADA.

Beta-glucosidase 2 (GBA2) is an enzyme involved in the metabolism of sphingolipids, it cleaves glucosylceramide into glucose and ceramide. GBA2 is highly sensitive to inhibition by the clinically licenced drug miglustat (Zavesca®), which passes the blood-brain barrier but does not cause major adverse effects. The physiological significance of the GBA2 enzymatic activity is therefore not clear. By contrast, mutations in the human *GBA2* gene are associated with hereditary spastic paraplegia 46 (SGP46) and Marinesco-Sjögren-like syndrome (MSS), which are neurological diseases on the ataxia-spasticity spectrum. To establish why pharmacologically inhibiting of GBA2 does not, but mutations in the *GBA2* gene do result in neurological diseases, we characterized a number of GBA2 mutants. We compared the cellular location of wild-type GBA2 (WT, 927 amino acids) with those of GBA2 mutants. While previous studies have suggested GBA2-WT to be localized at the ER, Golgi, and plasma membrane, we detected GBA2-WT at the plasma membrane, and, in a minority of cells, in the mitochondrial matrix, using confocal and electron microscopy. GBA2 mutants carrying single amino acid-substitutions were located at the plasma membrane, as judged by confocal microscopy. In contrast, confocal and electron microscopy showed that C-terminally truncated forms of GBA2 terminating after residues 233 or 339 were localized in the mitochondrial matrix. In addition, these mutants caused mitochondrial fragmentation and loss of membrane potential. By deletional analysis, we found that amino acids 160-200 were essential for the mitochondrial localization of the GBA2-339 mutant. Our results were supported by in *silico* analysis of the GBA2-339 amino acid sequence, identifying an internal mitochondrial targeting domain centered around amino acids 161-176. Altogether, we have established that GBA2 encompasses a functional mitochondrial targeting domain, which may be responsible for mitochondrial import of GBA2 under particular conditions. These findings raise the possibility of a physiologically relevant role for GBA2 in mitochondria, separate from its enzymatic activity. Further, in individuals with mutations in the *GBA2* gene, aberrant or defective mitochondrial localization of various mutant forms of GBA2 may cause neuronal dysfunction. Our work therefore provides new insights in the cell biology of GBA2 and the cell biological basis of neurological diseases. This work was supported by the Natural Sciences and Engineering Research Council (NSERC) of Canada, Dalhousie University Faculty of Medicine, Dalhousie University Department of Pediatrics, the IWK Health Centre (Halifax, Nova Scotia), and the Nova Scotia Health Research Foundation (NSHRF).

Gem1/Miro1 Promotes Mitochondrial-Derived Compartment Formation at ER-Mitochondria Contact Sites.

A. M. English, M. Schuler, J. M. Shaw, A. L. Hughes; Department of Biochemistry, University of Utah School of Medicine, Salt Lake City, UT.

During cellular stress, mitochondria initiate various quality control mechanisms to promote proper mitochondrial function. Recently, we discovered a novel mitochondrial quality control system that is conserved from yeast to mammals, called the mitochondrial-derived compartment (MDC) pathway. Our current data suggests that this system protects mitochondria from nutrient stress by selectively

removing metabolite transporters from mitochondria in response to elevated nutrients. Selective transporter removal occurs by sorting into a specialized membrane-bound compartment formed from mitochondria in conditions of nutrient excess, called an MDC. Although we know mitochondrial metabolite transporters are targeted by this pathway, we understand little about how cells form MDCs. To address this question, we performed super-resolution time-lapse imaging and microscopy-based screens in yeast to elucidate the machinery and mechanism of MDC formation. Through these approaches, we discovered that MDCs are large, organelle-like structures that localize to sites of ER-mitochondria contact. MDC formation requires the ERMES (ER-mitochondria encounter structure) complex and the ERMES-associated GTPase Gem1. Mutational analysis of Gem1 demonstrated that Gem1's GTPase domains, but not EF-hands, are required for MDC formation. Similar to our observations in yeast, we found that mouse embryonic fibroblasts (MEFs) lacking Miro1, the mammalian ortholog of Gem1, fail to form MDCs efficiently and that MDCs associate with Miro1 and ER tubules in MEFs. The specific role of ER-mitochondria contact sites in formation of yeast and mammalian MDCs is currently unclear. However, our preliminary data suggests that components of ER-mitochondria contacts sites may interact with cytoskeletal elements to promote formation of these specialized mitochondrial structures. Together, these results begin to illuminate the mechanisms underlying formation of MDCs, and identify a conserved function of the Gem1/Miro1 GTPase in nutrient-dependent mitochondrial remodeling.

Dissecting the Physiopathological Role of Sigma-1 Receptor Mutationin Distal Hereditary Motor Neuropathies.

S. Zanin[1], A. Petrucci[2], G. Vazza[3], R. Rizzuto[1], G. Pallafacchina[4]; [1]Dept Biomedical Science University of Padova, Padova, ITALY, [2]Neuromuscular and Rare Neurological Diseases Centre, San Camillo-Forlanini Hospital of Rome, Rome, ITALY, [3]Dept of Biology, University of Padova, Padova, ITALY, [4]Dept of Biomedical Science, Universiti of Padova and CNR Neuroscience Institute, Padova, ITALY.

Distal Hereditary Motor Neuropathies (dHMNs) are clinically and genetically heterogeneous neurological disorders characterized by degeneration of the lower motor neurons. To date, more then 20 dHMN genes have been identified but the genetic causes of most of the dHMN cases remain unknown. We have recently identified two causative mutations (E138Q and E150K) in the sigma-1 receptor (sigma-1R) encoded by the *SIGMAR1*gene, found in two Italian families affected by an autosomal recessive form of dHMN.Sigma-1R is a highly conserved chaperone protein of the endoplasmic reticulum (ER) which shares no homology with any mammalian protein. We found that sigma-1R substitutions behave as "loss-of-function" mutations affecting cell viability and altering Ca^{2+} homeostasis due to the derangement of ER-mitochondria tethering in neuroblastoma cells.Currently, we focused on the dissection of the molecular mechanisms underlying sigma-1R role in the etiopathology of dHMN using human skin fibroblasts from patients homozygous for the E150K mutation. We analyzed intracellular sigma-1R protein distribution and organelle morphology, and we investigated the global intracellular Ca^{2+} dynamics and the extent and distribution of ER-mitochondria tethers, which are one of the main determinants of mitochondria Ca^{2+} signalling. Our data clearly point out a significant disorganization of ER-mitochondria contact sites, and a consequent impairment of the global Ca^{2+} handling in patient fibroblasts compared to controls. Then, our electron microscopy analysis reveals a significant alteration of mitochondrial cristae in mutant fibroblasts compared to controls. Furthermore, patient cells show autophagy disturbance and upregulation of the Unfolded Protein Response (UPR) pathway. Concluding,

our data demonstrate the involvement of sigma-1R in the maintenance of cell homeostasis and protein quality control, highlighting its crucial role in the establishment of organelle structure, global Ca^{2+} signalling and proteostasis. Our data suggest that SIGMAR1gene mutations can cause motor neuron dysfunction in dHMN and point to the dysregulation of sigma-1R function as a critical aspect of neuronal degeneration in human neuropathies.

Decreased Pdzd8-mediated ER-mitochondria Contacts in Neurons Improve Fitness by Increasing Mitophagy.

V. L. Hewitt[1], L. Miller-Fleming[2], S. An dreazza[2], A. Sanchez-Martinez[2], A. Terriente-Felix[2], J. Prudent[2], A. Vagnoni[3], A. J. Whitworth[2], F. Polleux[1]; [1]Columbia University, New York, NY, [2]University of Cambridge, Cambridge, UNITED KINGDOM, [3]Kings College London, London, UNITED KINGDOM.

Organelle contacts are emerging as a critical biological interface playing many important roles ranging from regulation of calcium dynamics, mitochondrial fission and lipid biogenesis. Among the many roles of ER-mitochondrial contact sites is to help mediate mitochondrial quality control. The complex architecture combined with the longevity of neurons makes maintaining healthy neuronal mitochondria particularly important and challenging. We find that reducing ER-mitochondrial contacts by neuron-specific knockdown of *Pdzd8*, a recently identified tethering protein (Hirabayashi, Kwon et al., Science 2017) prolongs the locomotor activity and lifespan of *Drosophila melanogaster.* This phenotype correlates with an increase in mitophagy, suggesting that increased mitochondrial turn over and therefore improved mitochondrial quality control helps support neuronal health with aging. In contrast increasing ER-mitochondria contacts by expression of a synthetic tethering construct in neurons reduces the lifespan and general activity of the flies by disrupting mitochondrial transport and synapse formation. We also show that reducing ER-mitochondria contacts can rescue the motility defects in a fly model over-producing Amyloid-β and prolong the survival of flies fed with mitochondrial toxins. Together this data provides the first in vivo evidence that ER-mitochondria contacts mediated by the tethering protein PDZD8 are involved in mitochondrial maintenance and play a critical role in neuronal function and organismal fitness.

Mitochondria-Lysosome Contact Site Regulation of Mitochondrial Dynamics and Dysfunction in Charcot-Marie-Tooth Type 2.

Y. Wong, W. Peng, D. Krainc; Northwestern University, Chicago, IL.

Both mitochondria and lysosomes are essential for maintaining cellular homeostasis, and dysfunction of both organelles has been observed in multiple neurodegenerative diseases. We recently found that mitochondria-lysosome contact sites formed dynamically and were distinct from damaged mitochondria targeted into lysosomes for degradation. Contact formation was promoted by active GTP-bound lysosomal RAB7, and contact untethering was mediated by recruitment of the RAB7 GTPase-activating protein TBC1D15 to mitochondria by FIS1 to drive RAB7 GTP hydrolysis and thereby release contacts. Functionally, lysosomal contacts marked sites of mitochondrial fission, allowing regulation of mitochondrial networks by lysosomes, whereas conversely, mitochondrial contacts regulated lysosomal RAB7 GTP hydrolysis via TBC1D15. In addition, mitochondria undergo fission and fusion events, but the dynamics and regulation of a third event of inter-mitochondrial contact formation remain unclear. Using

super-resolution imaging, we demonstrated that inter-mitochondrial contacts frequently formed and played a fundamental role in mitochondrial networks by restricting mitochondrial motility. Inter-mitochondrial contact untethering events were marked and regulated by mitochondria-lysosome contacts which were modulated by RAB7 GTP hydrolysis. Moreover, inter-mitochondrial contact formation and untethering were further regulated by Mfn1/2 and Drp1 GTP hydrolysis respectively. Surprisingly, endoplasmic reticulum tubules were also present at inter-mitochondrial contact untethering events, in addition to mitochondrial fission and fusion events. Importantly, we found that multiple disease mutations linked to the peripheral neuropathy Charcot-Marie-Tooth Type 2 such as Mfn2 (CMT2A), RAB7 (CMT2B) and TRPV4 (CMT2C) converged on prolonged inter-mitochondrial contacts and defective mitochondrial motility, highlighting a role for mitochondria-lysosome contact regulation of inter-mitochondrial contacts in mitochondrial network regulation and neurodegeneration.

Dissecting the Crosstalk between Lysosomes and Mitochondria.

C. E. Hughes, T. K. Coody, M. Jeong, J. A. Berg, D. R. Winge, A. L. Hughes; University of Utah, Salt Lake CIty, UT.

Mitochondria perform a wide variety of important cellular functions, ranging from energy production, to metabolism, to innate immune signaling. Mitochondria do not exist in isolation, but in a wider cellular context in which their structure and function depends on the presence of other cellular organelles. Lysosomes, in particular, heavily influence mitochondrial function, and the lysosome-mitochondrial relationship is important for maintaining mitochondrial health. Disruption of this organelle interdependence is thought to be at the heart of cellular aging and cause numerous age-related diseases, but what drives the functional connection between lysosomes and mitochondria remains unknown. We carried out genetic screens in yeast to uncouple lysosomes (vacuoles in yeast) from mitochondria and better understand the mechanics of the vacuole-mitochondria relationship. From these screens, we found that an increase in cellular iron uptake restored mitochondrial respiration in the absence of vacuolar function. Likewise, iron suppressed defects in mitochondrial structure and function brought on by vacuolar dysfunction. These data suggest that the main role of vacuoles in mitochondrial function is maintenance of a pool of bioavailable iron. Consistent with this idea, vacuole-deficient cells are starved for iron, despite being iron replete. The lack of iron bioavailability caused by vacuole impairment was exacerbated by amino acids, in particular, cysteine. Given that an important role of the vacuole is the compartmentation of amino acids, and failure of vacuoles would result in a buildup of cytoplasmic amino acids, we propose that excess cytoplasmic amino acids cause a lack of iron bioavailability which negatively impacts mitochondrial function. How cytoplasmic cysteine limits iron bioavailability is an open question, but our data suggest a role for reactive oxygen species, known disruptors of iron homeostasis, in the process. Together, this work sheds light on the vacuole-mitochondria connection, and establishes compartmentation of amino acids as an important strategy cells use to limit the toxicity of excess cytoplasmic amino acids.

Bap31 Regulates Mitochondrial Function in Er-mitochondria Contact Sites.

T. Namba; Kochi university, Kochi, JAPAN.

The endoplasmic reticulum (ER) and mitochondria are essential organelles responsible for various cellular functions and are key components of cellular stress responsiveness. They are also hosts to an array of biological reactions that are critical for the survival and homeostatic adaptation of cells. Advances in cellular visualization technologies have revealed details regarding the organelle structure; specifically, the ER comprises large membrane-bound compartments, with a network extending throughout the cytoplasm and a membrane subdomain, the mitochondria-associated ER membrane, which is a highly conserved feature of eukaryotic cells, and appears to be in close contact with the mitochondria. Increasing evidence suggests that ER-mitochondria contact sites serve as an important cellular signaling platform associated with several important functions, including Ca^{2+} storage, lipid biogenesis, mitochondrial division, and induction of autophagy. Thus, these contact sites are involved in the regulation of cellular biological reactions; however, their role in cellular homeostasis and stress responses remains unclear. Here, we demonstrate that the ER membrane protein, BAP31, acts as a key factor in mitochondrial homeostasis to stimulate the constitution of the mitochondrial complex I by forming an ER-mitochondrial bridging protein complex. Within this complex, BAP31 interacts with mitochondria-localized proteins, including Tom40, to stimulate the translocation of NDUFS4, the component of complex I from the cytosol to the mitochondria. Disruption of the BAP31-Tom40 complex inhibits mitochondrial complex I activity and oxygen consumption by the decreased NDUFS4 localization to the mitochondria. Thus, the BAP31-Tom40 ER-mitochondria bridging complex mediates the regulation of mitochondrial function and plays a role as a novel stress sensor, representing a mechanism for the establishment of ER-mitochondrial communication via contact sites between these organelles.

P540/B553

Mitochondrial AAA+ Proteins and Their Role in Mitochondria-ER Contact Sites.

S. Zelman, M. Kim, E. Vierling; University of Massachusetts, Amherst, MA.

Mitochondria play critical roles not only in primary metabolism as a central organelle for ATP generation, but also in responding to abiotic stresses. We identified a mutation in the *MTERF18 (Mitochondrial Transcription Termination factor)/SHOT1* (*Suppressor of hot1-4 1*) gene in *Arabidopsis thaliana* that enables plants to better tolerate heat and oxidative stresses, presumably due to reduced oxidative damage, but the exact molecular mechanism of the heat tolerance is unknown. In order to reveal the stress tolerance mechanisms of *mterf18*/*shot1* mutations, it is critical to understand the molecular defects of the mutant and to identify the molecular targets of the MTERF18/SHOT1 protein. MTERF18/SHOT1, a mitochondrial matrix protein, was found to bind to membrane-spanning mitochondrial AAA+ proteins homologous to ATAD3a of humans and other multicellular eukaryotes. Arabidopsis has four ATAD3a homologues in two clades, and plants require one gene from each clade for viability. Previous studies of the topology and ATPase activity of ATAD3a suggest a role in endoplasmic reticulum-mitochondria contact sites. These sites are poorly defined in plants, and their relationship to heat stress tolerance is intriguing. To better understand ATAD3 function we have expressed and purified the soluble, matrix-located, catalytic C-terminal ATPase domain of these proteins in order to assay their ATPase activity and oligomerization states. Transgenic plants with fluorescently labelled ER and mitochondria have been generated to observe effects of the MTERF18/SHOT1 mutation

on ER-mitochondria dynamics. In addition, *in-silico* structural analyses of the four ATAD proteins are being conducted to connect their structures to putative functions based on homology to known and characterized proteins. These studies of the four ATAD3 proteins will provide insights into ER-mitochondrial contact sites in plants, and into their link to MTERF18/SHOT1 and heat stress tolerance.

The Interaction between EBP50 and VDAC1 Mediates Cytoprotective Signaling on Mitochondria.

P. CHANG[1], T. JOU[1,2]; [1]Institute of Molecular Medicine, National Taiwan University, Taipei, TAIWAN, [2]Graduate Institute of Clinical Medicine, National Taiwan University, Taipei, TAIWAN.

Mitochondria, the organelles controlling ATP production and cellular metabolism, play a vital role in a number of cellular stress responses by communicating with other cellular compartments, for example, mitochondria-associated membranes (MAMs), the tightly membrane contact site between mitochondria and endoplasmic reticulum (ER). We recently found a scaffold protein, Ezrin/radixin/moesin (ERM)-binding phosphoprotein 50 protein (EBP50), plays a cytoprotective role on mitochondria. Knockdown of EBP50 elicited severe mitochondrial morphological change from fusion to fission and augmented apoptotic rate upon H_2O_2-induced stress and could be rescued by overexpressing siRNA resistant construct of EBP50 in Madin-Darby Canine Kidney (MDCK) cells. Furthermore, PDZ1 domain of EBP50 interacted with one of pivotal MAMs proteins, voltage-dependent anion channel 1 (VDAC1), which is localized on outer mitochondrial membrane (OMM). The N-terminus of VDAC1 regulates its oligomerization and channel activity. Amine-terminal deletion (aa 1-27) of VDAC1 diminished EBP50-VDAC1 interaction while carboxyl-terminal deletion retained an intact association. Moreover, the central component of the translocase of outer membrane (TOM) Tom20 also participated in EBP50-VDAC1 interaction. Our study paves the way for unraveling the detailed mechanisms and provides molecular insights into how to protect mitochondria from damaging during stress response.

P542/B555

Er-mitochondria Contact Sites during Mitosis.

F. Yu; Weill Cornell Medicine Qatar, Doha, QATAR.

Recent work demonstrates that organelles contact one another and that these close membrane contact sites (MCS) are functionally critical to maintain organelle and cellular homeostasis. MCS between mitochondria and ER (referred to as MEM as well) are some of the best characterized form hotspots for different cellular processes. Mitochondria are powerhouses for cellular energy production and play a crucial role in cell metabolism under both physiological and pathological conditions. The ER is the major site of lipid synthesis and intracellular Ca^{2+} store. The ER-Mito MCSs provide a way for lipid trafficking according to the metabolic needs of the cell, and coordinate Ca^{2+} signaling and stress responses. The ER-Mito MCSs enable efficient uptake of the high local Ca2+ concentration released from the ER into mitochondria through mitochondrial Ca2+ transporters to regulate mitochondrial function. During the cell cycle, ER and mitochondria undergo dramatic reorganization and morphological changes. The ER transforms from a mixed sheets and tubules network to almost exclusively sheets structure during mitosis and the majority of mitochondria fragment. However, the dynamics of ER-Mito MCSs during cell division are still not clear. In the current study, we use EM and a split GFP approach to study ER-Mito MCSs during mitosis. We analyze ER-Mito MCSs distribution and dynamics during mitosis. Our data

demonstrate that ER-Mito MCSs are dynamic structures that undergo active remodeling during cell division.

Dietary Fatty Acids Promote Lipid Droplet Diversity through Seipin Enrichment in an Subdomain of the Endoplasmic Reticulum.

Z. CAO[1], Y. Hao[1], C. Fung[1], Y. Lee[1], P. Wang[2], X. Li[3], K. Xie[4], W. Lam[1], Y. Qiu[1], B. Tang[5], G. Shui[6], P. Liu[4], J. Qu[3], B. Kang[2], H. Mak[1]; [1]Division of Life Science, the Hong Kong University of Science and Technology, Hong Kong SAR, CHINA, [2]School of Life Science, the Chinese University of Hong Kong, Hong Kong SAR, CHINA, [3]Biophotonics Research Laboratory, Department of Electronic and Computer Engineering, the Hong Kong University of Science and Technology, Hong Kong SAR, CHINA, [4]Institute of Biophysics, Chinese Academy of Sciences, Beijing, CHINA, [5]Department of Chemistry, the Hong Kong University of Science and Technology, Hong Kong SAR, CHINA, [6]Institute of Genetics and Developmental Biology, Chinese Academy of Sciences, Beijing, CHINA.

Lipid droplets (LDs) are conserved organelles that are crucial for proper compartmentalization of fat at the subcellular level. They serve as the primary sites for storing excess neutral fat. Recent studies have yielded mechanistic insights on the biogenesis and expansion of LDs that highlighted the crucial roles of endoplasmic reticulum (ER)-LD contacts. Nonetheless, outstanding questions remain on how these contacts are specifically established and preserved. Here, we report that a subpopulation of lipid droplet is defined by metabolite-modulated targeting of the *C. elegans* seipin ortholog, SEIP-1. Mutations in seipin cause the most severe form of lipodystrophy in human. Similarly, in *C. elegans*, deficiency of SEIP-1 reduces the size of a subset of LDs while over-expression of SEIP-1 has the opposite effect. Ultrastructural analysis reveals SEIP-1 enrichment in an endoplasmic reticulum (ER) subdomain, which co-purifies with LDs. An alyses of *C. elegans and* bacterial genetic mutants indicate a requirement of polyunsaturated fatty acids (PUFAs) and microbial cyclopropane fatty acids (CFAs) for SEIP-1 enrichment, as confirmed by dietary supplementations. In mammalian cells, heterologously expressed SEIP-1 engages nascent lipid droplets and promotes their subsequent expansion in a conserved manner. Our results provide the first characterization of the *C. elegans* seipin ortholog. We propose that microbial and polyunsaturated fatty acids serve unexpected roles in regulating cellular fat storage by fostering ER-LD contacts and promoting LD diversity. In an attempt to identify additional components that distinguish sub-populations of LDs, we have conducted proteomic analysis on purified LDs that are associated with or are devoid of SEIP-1(+) peri-LD cages. Results on the initial characterization of candidate molecular markers for LD sub-populations will be reported.

P544/B557

Characterization of Cerebellar Ataxia Disease-associated Snx14 in Fatty Acid Metabolism.

S. Datta, H. Hariri, J. Bowerman, M. Henne; University of Texas Southwestern Medical Center, Dallas, TX.

Fatty acids (FAs) are important cellular metabolites which are utilized by the cells to perform important functions, such as, generation of ATP, membrane biosynthesis, and cell signaling. An imbalance in FA processing causes them to accumulate resulting in lipotoxicity - a primary cause behind metabolic and neurological disorders. To protect cells from lipotoxic stress, excess lipids are stored in the form of lipid

droplets (LDs) which emerge from the endoplasmic reticulum (ER). How the budding of LDs from the ER is regulated is not completely understood. We showed that sorting nexin protein Snx14, implicated in cerebellar ataxia disease SCAR20, is a marker for ER-LD contacts where it promotes oleate-induced LD growth. We used proximity based APEX2 technology and structure-function analysis to show that Snx14 anchors to the ER via its N-terminal transmembrane domain and interacts with LD surface via its C-terminal amphipathic helix. Loss of Snx14 perturbs LD morphology whereas Snx14 overexpression extends ER-LD contacts and promotes LD biogenesis. To further understand the implications of Snx14 in regulating ER-LD contacts, we conducted a proteomic screen to determine the interactors of Snx14 using proximity based APEX2 method. Proximity labeling of Snx14 revealed known LD proteins as well as FA desaturase SCD1 (stearoyl-CoA desaturase-1). We validated the interaction of SCD1 with Snx14 by co-immunoprecipitation experiments. Furthermore, $SNX14^{KO}$ cells are hypersensitive to palmitic acid-induced lipotoxicity and display altered ER morphology. Also, loss of Snx14 affects SCD1 expression. Current and future studies aim to mechanistically dissect the interplay of Snx14 and SCD1 in maintaining lipid homeostasis.

P545/B558

Mechanism of Lipid Droplet/Mitochondria Contacts and Role of Perilipin 5 in Lipid Metabolism.

G. E. Miner, S. Cohen; University of North Carolina Chapel Hill, Chapel Hill, NC.

The lipid droplet (LD) serves as a cellular lipid store; however recent work has highlighted the ability of LDs to regulate intracellular lipid trafficking. Perilipins are LD proteins which function as lipolytic barriers and protect the cell from lipotoxicity as well as excess reactive oxygen species. A recently characterized member of the family, Perilipin 5 (Plin5), is enriched in β-oxidizing tissues where it serves as a lipolytic barrier under basal conditions. Upon protein kinase a (PKA)-stimulated phosphorylation, however, Plin5 promotes lipolysis through recruitment of the lipase ATGL and its activator CGI-58. In addition to playing a role in lipolytic control, Plin5 contains a unique C-terminal domain which has been shown to promote contacts between LDs and mitochondria (Mito). However, the mechanism by which this occurs and the physiological significance of these contacts remains to be elucidated. Utilizing predictive modeling we have identified and generated constructs containing a minimal contact domain capable of inducing LD/Mito contacts. Overexpression of Plin5 lacking this contact domain (Plin5 CΔ) leads to accumulation of lipid droplets to the same degree as full-length Plin5, indicating that LD/Mito contacts are not required for the lipolytic barrier function of Plin5. Affinity purification-mass spectrometry utilizing Plin5 and Plin5 CΔ constructs indicates a role for previously unidentified protein interactors to mediate LD/Mito tethering. To assess the physiological roles of Plin5's functional domains in fatty acid (FA) trafficking we have utilized a fluorescent FA pulse-chase assay. Our data demonstrates that efficient FA trafficking in response to nutrient deprivation is dependent on LD/Mito contacts as well as phosphorylation of Plin5 at serine 155, a known PKA phosphorylation site. Considering the expression of Plin5 primarily in β-oxidizing tissue, we hypothesize that LD/Mito contacts are not primarily involved in FA storage but rather enhance the transfer of FAs from LD to mitochondria under physiological conditions that stimulate PKA activity, leading to increased FA oxidation.

P546/B559

Kinesin Acts as a Tether between Lipid Droplets and the Endoplasmic Reticulum.

J. Singh, M. Kumar, R. Mallik; Tata Institute of Fundamental Research(TIFR), Mumbai, INDIA.

Lipid Droplets (LDs) are dynamic cellular organelles specialized in storing and supplying lipids for metabolic processes. Mutations in proteins associated with LDs result in pathologies such as non-alcoholic fatty liver disease and congenital lipodystrophies. A recent report from our lab suggested that the kinesin-1 motor transports LDs to the smooth endoplasmic reticulum (sER) in hepatocytes, where-after lipids inside LDs can be channeled for production of lipoproteins at the sER[1]. We subsequently also showed that this channeling is controlled in the liver through Insulin signaling in a manner that maintains lipid homeostasis in blood across fed/fasted states[2]. Here we have explored the interaction between LDs, kinesin, and ER in non-hepatocyte (COS7) cells. The tubular ER network can be visualized easily along with LDs in live COS7 cells, making them a good system to study LD-ER interactions and dynamics. LDs are seen to move along the ER in a restricted manner in normal cells. However, contrary to expectations, loss of kinesin-1 leads to a dramatic increase in motion of the LDs along the ER tubules. Interestingly, the same effect is not observed upon dynein inhibition. Together, these results lead us to hypothesize that kinesin acts as a "tether" to keep LDs close to the ER. Optical trapping experiments show enhanced force-generation events that upon loss of kinesin, and these events are now ascribed to the dynein motor. Rescue experiments with truncated forms of kinesin-1 show that kinesin does not use its ATPase activity in performing this tethering function. Kinesin-1 knockdown leads to aberrant trafficking of proteins and lipids between LDs and the ER. Interestingly, loss of kinesin-1 phenocopies the knockout of Seipin, a gene involved in a severe form of congenital lipodystrophy. We are currently investigating whether kinesin facilitates the maintenance of ER-LD contacts via interaction with Seipin. Our work opens the possibility that kinesin-1 on LDs may function as a motor or a tether depending on yet-to-be-understood cellular requirements. **References:-** 1- Kinesin dependent Mechanism for Controlling Triglyceride Secretion from the Liver, Priyanka Rai et al, PNAS 114, 12958-12963 (2017) 2- Insulin activates Intracellular transport of Lipid Droplets to release Triglycerides from the Liver, Mukesh Kumar et al, Journal of Cell Biology (2019, in press)

P547/B560

Apolipoprotein E Is an Astrocyte Lipid Droplet Protein at the Intersection of Lipid Storage and Secretion.

I. Windham, S. Cohen; University of North Carolina-Chapel Hill, Chapel Hill, NC.

Neurons require large amounts of lipid to facilitate the development of mature synapses, but do not produce enough to meet these requirements. Lipids synthesized in other organs and packaged into circulating lipoproteins cannot pass through the blood brain barrier. Therefore, a majority of brain lipids are made in situ in the brain. Astrocytes, a type of glial cell involved in regulating synapse formation, maturation, and elimination, synthesize lipids and supply them to neurons via secreted lipoprotein particles or store them in cytoplasmic lipid droplets. The primary protein component of lipoprotein particles secreted by astrocytes is Apolipoprotein E (ApoE), the major genetic risk factor for late-onset Alzheimer's disease. Previously, a proximity labelling-based proteomics screen identified ApoE as a candidate protein found on lipid droplets, intracellular organelles that store esterified lipids. We hypothesize that ApoE can localize to lipid droplets in astrocytes and is involved in the regulation of lipid storage. To test whether ApoE localizes to lipid droplets (LDs), we expressed a fluorescently-tagged

ApoE construct in primary rat astrocytes. We found that ApoE localizes to LDs in some cells, while in others it is enriched in the Golgi and highly mobile vesicles. This localization was confirmed by immunostaining of endogenous ApoE. The C-terminal domain of ApoE mediates lipid droplet association, while the N-terminal domain is required for ApoE to subvert translocation into the ER. ApoE localization to LDs is dependent on nutrient availability, and correlates with increased neutral lipid storage. Together, these results suggest that ApoE plays a novel role in lipid storage and metabolism in a subset of astrocytes. We propose that ApoE is at the intersection of lipid storage and secretion, and can shift the balance between the two in response to changing environmental or developmental conditions.

The Roles of Pex30 and Family Members in Organelle Biogenesis at the Endoplasmic Reticulum.

J. P. Verissimo Ferreira, P. Carvalho; Sir William Dunn School of Pathology, University of Oxford, Oxford, UNITED KINGDOM.

Lipid droplets (LDs) and peroxisomes are ubiquitous organelles with central roles in eukaryotic cellular metabolism. LD biogenesis and formation of pre-peroxisomal vesicles (PPVs), which are involved in peroxisomes biogenesis, occur at the same endoplasmic reticulum (ER) sites and involves cooperation between the seipin complex and Pex30p. Intriguingly, Pex30p shares the same domain architecture with four other proteins - Pex28p, Pex29p, Pex31p and Pex32p - constituting the family of the dysferlin domain-containing peroxins. However, whether these proteins are redundant or have distinct functions is unclear. To study the function of these proteins, we first endogenously tagged them and analysed their subcellular location under different conditions and genetic backgrounds. All of the Pex30-like proteins localise to the ER and form-puncta-like structure, and a fraction of these puncta correspond to ER-to-peroxisome contact sites (EPCONS). Additionally, our data suggest that the Pex30p-like proteins localise to multiple but distinct organelle contact sites in response to different physiological contexts. In turns, Pex30p-like proteins recruit Pex30p to these contact sites. In addition, we also observe that Pex30p is required for stability of Pex30-like proteins at these contact sites. These data suggest that Pex30p and Pex30p-like proteins form pairwise functional complexes at the interface of the ER with other organelles. We propose that Pex30p family of proteins are a general regulator of organelle contact sites with important roles in membrane and lipid homeostasis.

Lipid Storage in Starved *Tetrahymena Thermophila*.

B. Ahn, H. Nilsson, L. Listenberger; St. Olaf College, Northfield, MN.

Lipid droplets are increasingly recognized as important and dynamic organelles in all cells. The pathways contributing to the formation and degradation of lipid droplets have been well-studied in a variety of organisms, including mouse, human, roundworm, fruit flies, and yeast. Our experiments aim to determine the cellular pathways that contribute to lipid droplet homeostasis in *Tetrahymena thermophila,* a single-celled ciliate. In this study, we demonstrate increased neutral lipid storage in *Tetrahymena* following starvation. Lipid droplet number and size increase within 3 hours of starvation, remain elevated for an additional 72 hours and then begin to decline. Pulse-chase experiments using a fluorescent fatty acid analog (Red C12) show that lipid trafficking to lipid droplets in starved *Tetrahymena* occurs along a similar time frame. We hypothesize that *Tetrahymena* mobilizes lipids in lipid droplets to serve as substrates for beta-oxidation. However, our results suggest that lipophagy does

not play a role in this process. Monodansylcadaverine, a fluorescent label for autophagosomes, fails to colocalize with lipid droplets in starved *Tetrahymena.* Future studies will use inhibitors of cytosolic lipases and/or lipophagy to investigate the pathways of lipid droplet metabolism in *Tetrahymena.* We have also identified several novel lipid droplet-associated proteins from starved *Tetrahymena* following lipid droplet isolation, SDS-PAGE and mass spectrometry. Ongoing analysis of these proteins will provide further insight into mechanisms of lipid storage in starved *Tetrahymena thermophila.*

The Lipid Droplet Regulator Seipin Mediates Fatty Acid Homeostasis Necessary for the Formation of the Permeability Barrier in the *Caenorhabditis Elegans* Embryo.

L. Huang[1], X. Bai[2], S. Chen[3], R. Chen[1], A. Golden[2], C. Wang[3]; [1]Institute of Molecular Biology, Academia Sinica, Taipei, TAIWAN, [2]Genetics of Early Development, Laboratory of Biochemistry and Genetics, NIDDK/NIH, Bethesda, MD, [3]Institute of Plant and Microbial Biology, Academia Sinica, Taipei, TAIWAN.

The organelle lipid droplet (LD) maintains lipid homeostasis through storing and metabolizing fats in response to diverse stimuli. How these activities connect to animal growth and development are poorly understood. Seipin, crucial for adipocyte development in human, is an evolutionarily conserved protein regulating LD assembly. We found that *Caenorhabditis elegans* deleted for seipin ortholog, SEIP-1, reduced hatch ratio. The defect is largely due to the failure in synthesizing the permeability barrier that protects developing embryos from penetration of small molecules. SEIP-1 is widely expressed, enriched in major fat storage tissues as well as oocyte and embryos. SEIP-1 deletion animals accumulate aberrant LDs, consistent with its crucial role in LD size maintenance. Lipidomic analyses reveal that the SEIP-1 deleted embryo has altered fatty acid (FA) homeostasis with a significant reduction in polyunsaturated FA (PUFA) levels, consistent with the PUFA biosynthetic gene expression pattern. Interestingly, dietary supplementation with selected PUFA, namely GLA and DGLA, largely relieves the reproductive defect of the SEIP-1 deletion worm via the restoration of permeability barrier during early embryogenesis. Together, we propose that SEIP-1 maintains fatty acid homeostasis in order to orchestrate proper PUFA supplies for permeability barrier synthesis during early *C. elegans* development.

P551/B564

Spastin Tethers Lipid Droplets to Peroxisomes and Directs Fatty Acid Trafficking through ESCRT-III.

C. Chang[1], A. Weigel[1], M. Ioannou[1], H. Pasolli[1], C. Xu[1], D. Peale[1], G. Shtengel[1], M. Freeman[1], H. Hess[1], C. Blackstone[2], J. Lippincott-Schwartz[1]; [1]HHMI Janelia Research Campus, Ashburn, VA, [2]National Institute of Health, Bethesda, MD.

Lipid droplets (LDs) are neutral lipid storage organelles that transfer lipids to various organelles including peroxisomes. Here, we show that the hereditary spastic paraplegia protein M1 Spastin, a membrane-bound AAA ATPase found on LDs, coordinates fatty acid (FA) trafficking from LDs to peroxisomes through two interrelated mechanisms. First, M1 Spastin forms a tethering complex with peroxisomal ABCD1 to promote LD-peroxisome contact formation. Second, M1 Spastin recruits the membrane-shaping ESCRT-III proteins IST1 and CHMP1B to LDs via its MIT domain to facilitate LD-to-peroxisome FA trafficking, possibly through IST1- and CHMP1B-dependent modifications in LD membrane morphology. Furthermore, LD-to-peroxisome FA trafficking mediated by M1 Spastin is required to relieve LDs of lipid peroxidation. M1 Spastin's dual roles in tethering LDs to peroxisomes and in recruiting ESCRT-III

components to LD-peroxisome contact sites for FA trafficking may underlie the pathogenesis of diseases associated with defective FA metabolism in LDs and peroxisomes.

Regulation and Compartmentalization of Fatty Acid Metabolism at Membrane Contact Sites.

H. Hariri, M. Henne; UT Southwestern Medical Center, DALLAS, TX.

Fatty acids (FA) are toxic to cells and thus sequestered in the form of triacylglycerides in cytoplasmic organelles called lipid droplets (LD) that bud from the endoplasmic reticulum (ER). We recently showed that, in response to nutrient stress, yeast LDs cluster adjacent to the vacuole/lysosome, but how this LD accumulation is spatially coordinated remains unknown. We report that ER-vacuole tether Mdm1 spatially regulates LD biogenesis at ER-vacuole contacts to maintain ER lipid homeostasis and protect the cell from lipotoxicity. Mdm1 binds to LDs and free FAs via its uncharacterized PX-Associated (PXA) domain, and co-enriches with fatty acyl-CoA ligase Faa1 at LD bud sites. Consistent with this, loss of *MDM1* perturbs free FA activation and subsequent TAG generation, elevating cellular FAs that perturbs ER morphology and sensitizes yeast to FA-induced lipotoxicity. Our data support a model where Mdm1 organizes free FA activation adjacent to the vacuole to promote LD production in response to stress. This maintains ER lipid homeostasis by efficiently segregating away toxic FAs into LDs. These findings establish a functional significance for organelle contacts in organizing FA metabolism and lipid flux. We are currently investigating the mechanism by which Mdm1 coordinates the metabolic fates of free FAs at organelle contact sites through a combination of in *vitro* reconstitution, global lipidomics, and state-of-the-art cryogenic focused ion beam (Cryo-FIB) milling and electron microscopy.

P553/B566

Phase-partitioning of Vacuole Membrane Directs Inter-organellar Sterol Trafficking to Coordinate Mitochondrial Development and Energy Metabolism with Macro-autophagy.

A. Y. Seo[1], F. Sarkleti[1], I. Budin[2], J. Lippincott-Schwartz[1]; [1]HHMI-Janelia Research Campus, Ashburn, VA, [2]University of California San Diego, San Diego, CA.

Cellular ability to switch from aerobic fermentation to mitochondrial oxidative phosphorylation is the key underlying survival mechanism for many organisms during glucose starvation. However, how cells drive this metabolic transition remains unclear. Using a yeast model system, we demonstrate that to sustain mitochondrial respiration, by which lipid is now utilized as the major energy source, starved cells activate a distinct inter-organellar lipid pipeline to mitochondria from vacuole/lysosome via endoplasmic reticulum (ER). We find that macro-autophagy initiates this new lipid route by rapidly relocating endosomal membrane compartments to the vacuole. This prompted vacuole membrane phase separation, generating ergosterol-enriched liquid-ordered membrane-like (Lo) domains. Through the Lo domain, vacuole-ER contacts formed, and vacuolar ergosterols cycled back to ER for mitochondria and lipid droplet (LD) developments. With a control of vacuolar ergosterol pools by LD sequestration of excessive sterol lipids, the Lo domains further differentiated, and vacuolar LD recruitment and digestion began to work in play for recycling of LD-stored fat molecules. Our findings that the Lo differentiation occurs only when mitochondrial respiration promotes macro-autophagy suggested a feedback interplay between mitochondria and vacuole during the remobilization of the needed substitute energy source from LDs. Taken together, our results reveal an unknown organellar mechanism that mediates metabolic

reprogramming in glucose-starved cells, and highlight the importance of inter-organellar communications for cell and organism's survival under metabolic stress.

Extended Synaptotagmin Regulates Plasma Membrane-endoplasmic Reticulum Contact Site Structure and Lipid Transfer Function in *Vivo*.

R. PADINJAT, V. Nath, S. Mishra, B. Basak, D. Trivedi; NATIONAL CENTRE FOR BIOLOGICAL SCIENCES, BANGALORE, INDIA.

Inter-organelle communication by membranes positioned in close proximity is proposed to occur at Membrane Contact Sites (MCS). MCS between the plasma membrane (PM) and endoplasmic reticulum (ER) are thought to support localized biochemical events including lipid transfer between these membranes and several proteins that localize to ER-PM contact sites have been identified. The extended synaptotagmins (Esyt) are proteins localized to MCS in both yeast and cultured mammalian cells. Several models of their localization and function at ER-PM contact sites are described. However, loss of all three Esyts in yeast (*tcb1, 2 and 3*) or mouse (*Esyt1, 2 and 3*) shows minimal phenotypes raising questions about the requirement of Esyt for cell physiology in *vivo. In Drosophila* photoreceptors, G-protein coupled phosphatidylinositol 4,5 bisphosphate (PIP_2) turnover is required for phototransduction. The phosphatidylinositol transfer protein (RDGB) is localized to ER-PM contact sites in photoreceptors and is required to support normal light responses in *vivo*. Depletion of RDGB or its mis-localization away from MCS results in a reduced light response and retinal degeneration. Using CRISPR/Cas9 genome engineering, we created a protein null mutant of the only extended synaptotagmin in *Drosophila (dEsyt)* and studied its impact on photoreceptor structure and function. Using electron microscopy analysis, we find that *dEsyt* is required to maintain the structure and function of ER-PM MCS in *vivo*. Loss of dEsyt results in progressive mislocalization of RDGB protein during illumination ultimately leading to retinal degeneration. Importantly, loss of *dEsyt* enhanced the in *vivo* phenotypes of $rdgB^{9}$, a hypomorphic allele with reduced levels of RDGB protein. $rdgB^{9};dEsyt^{KO}$ double mutants show an enhanced rate of retinal degeneration, reduced light responses and slower rates of plasma membrane PIP_2 resynthesis compared to $rdgB^{9}$. Thus, we demonstrate that dEsyt function is required to support ER-PM contact site structure of photoreceptors and the function of RDGB at this location in *vivo*.

P555/B568

Ca2+-dependent Regulation and Lipid Transport Mechanism of Extended Synaptotagmin 1.

X. Bian[1], Z. Zhang[2], Q. Xiong[1], Y. Saheki[3], C. Lin[1], P. De Camilli[1]; [1]Yale School of Medicine, New Haven, CT, [2]University of Wisconsin-Madison, Madison, WI, [3]Nanyang Technological University, Singapore, SINGAPORE.

The extended synaptotagmins (E-Syts) are intrinsic membrane proteins of the endoplasmic reticulum (ER) that bind the plasma membrane (PM) via C2 domains and transport lipids between the two membranes via SMP domains. Of the five C2 domains of E-Syt1, only C2A and C2C contain Ca2+-binding sites. Using liposome-based assays, we showed that Ca2+ binding to C2C promotes E-Syt1-mediated membrane tethering by releasing an autoinhibitory interaction that prevents C2E from binding to PI(4,5)P2-rich membranes. Additionally, Ca2+ binding to C2A enables lipid transport by releasing a distinct and charge-based autoinhibitory interaction between this domain and the SMP domain. To gain insight into whether the SMP domains can transport lipids between two adjacent bilayer by shuttling

between them, rather than by directly bridging the two bilayers to allow sliding of lipids within its hydrophobic groove, we developed DNA-origami nanostructures that organize size-defined liposomes at precise distances and allow lipid transfer between them. Pairs of DNA-ring-templated donor and acceptor liposomes were docked through DNA pillars, which determined their distance. The SMP domain was anchored to donor liposomes via an unstructured linker, and lipid transfer was assessed via a FRET-based assay. We found that lipid transfer can occur over distances that exceed the length of an SMP dimer. Thus, we propose a model in which Ca2+ binding reverses the autoinhibited state of E-Syt1 to promote membrane tethering and lipid transport via the shuttling of its SMP domain between the two adjacent membranes.

P556/B569

PDZD8 Mediates a Rab7 Dependent Interaction of the Endoplasmic Reticulum with Late Endosomes and Lysosomes.

A. Guillén Samander, P. De Camilli; Yale University, New Haven, CT.

The endoplasmic reticulum (ER) is the subcellular compartment where most membrane lipids are synthesized and where lipid metabolites generated in other membranes are returned to be reutilized. Lipid flux from and to the ER is partially mediated by proteins that are localized at sites of close appositions between its membrane and those of other membranous organelles and that contain lipid transport modules. The SMP domain is one such module. Proteins harboring this domain also function as tethers between the two adjacent membranes. Here we focus on PDZD8, an SMP domain containing protein, previously reported to act at contacts between the ER and mitochondria (PMID: 29097544). PDZD8 is an ER-resident protein inserted in the ER membrane through an N-terminal transmembrane domain. The cytosolic portion of PDZD8 contains the SMP domain followed by a PDZ domain, a C1 domain and a C-terminal coiled-coil region. Using confocal microscopy, we have now found that both PDZD8-EGFP transfected in fibroblastic cells and PDZD8 tagged at the endogenous locus in Neuro2A cells, are not only present throughout the ER but also enriched at regions of the ER that contact a subset of late endosomes/lysosomes. Recruitment of PDZD8 to these vesicles is mediated by its interaction with the small GTPase Rab7. The interaction is highly dependent on the GTP-bound state of Rab7 and is mediated by the most C-terminal region of PDZD8 which contains a coiled-coil domain. Confocal microscopy further showed that overexpression of both PDZD8 and Rab7 (more so of the mutant constitutively active Rab7) induces massive enwrapping by the ER of late endosomes/lysosomes with PDZD8 being concentrated at the interface between the ER and these organelles. Electron microscopy confirmed the occurrence of massive and very tight appositions between the ER and late endosomes/lysosomes in these cells. As Rab7 is a key modulator of endosomal maturation, these findings raise the possibility that the lipid transfer activity of PDZD8 may have a role in this transition. It would be of interest to determine whether the previously reported defect in mitochondrial function resulting from the absence of PDZD8 may be an indirect effect of late endosome/lysosome dysfunction (PMID: 29097544).

P557/B570

Metabolic Integration of Signaling and Housekeeping Pools of Phosphoinositides between the ER and Plasma Membrane.

Y. KIM, N. Sengupta, J. Pemberton, T. Balla; NICHD, NIH, Bethesda, MD.

Phospholipase C (PLC)-catalyzed hydrolysis of phosphatidylinositol 4,5-bisphosphate (PI(4,5)P_2) is a major signaling modality in all metazoan organisms. During prolonged stimulation, the limited plasma membrane (PM) pool of PI(4,5)P_2 is replenished using phosphatidylinositol (PI) that is synthesized in the endoplasmic reticulum (ER). PI synthesis is strongly stimulated during PLC activation and it is believed that this increase is the result of recycling both hydrolytic products of PI(4,5)P_2 hydrolysis, inositol 1,4,5-trisphopshate and diacylglycerol (DG). An important step in the recycling process is the conversion of DG to phosphatidic acid (PA) within the PM and the subsequent transport of PA from the PM to the ER. PI is synthesized from PA by two enzymatic reactions that occur exclusively in the ER, with cytidine diphosphate-DG (CDP-DG) being a short-lived intermediate. In the ER, there are several sources of PA, including PA derived from *de novo* synthesis, phospholipase D (PLD)-mediated phosphatidylcholine (PC) hydrolysis or from the phosphorylation of ER-localized DG by DG-kinases. To what extent these different sources of PA can be used for PI synthesis during PLC activation is poorly understood. Here, we used a combination of isotope labeling and lipidomics analyses in agonist-stimulated HEK293 cells to investigate the metabolic isolation of the various sources of PA that are used to increase PI synthesis. Our studies show that PLC activation primarily initiates the recycling of the PM-derived hydrolytic products from PI(4,5)P_2 breakdown, but also enhances *de novo* PA synthesis and its conversion into PI. Notably, the unsaturated PI(4,5)P_2 pools are resynthesized significantly faster than the more saturated ones suggesting a slower integration of saturated PI(4,5)P_2 pools into the signaling pool during prolonged PLC activation. These findings have significant implications for understanding the recycling and distribution of PI lipids between the ER and other organelles during PLC activation while also shedding light on the fatty acid side chain remodeling that occurs during these processes.

***Grasp55*$^{-/-}$ Mice Display Impaired Fat Absorption and Resistance to High-fat Diet-induced Obesity.**

J. Kim; the Catholic University of Korea College of Medicine, Seoul, KOREA, REPUBLIC OF.

The Golgi apparatus plays a central role in the intracellular transport of macromolecules. However, molecular mechanisms of Golgi-mediated lipid transport remain poorly understood. Here, we show that genetic inactivation of the Golgi-resident protein GRASP55 in mice reduces whole-body fat mass via impaired intestinal fat absorption and evokes resistance to the weight gain induced by a high-fat diet. Mechanistic analyses revealed that GRASP55 participates in the Golgi-mediated lipid droplet (LD) targeting of some LD-associated lipases, such as ATGL and MGL, which is required for sustained lipid supply for chylomicron assembly and secretion. Consequently, GRASP55 deficiency led to reduced chylomicron secretion and abnormally large LD formation in intestinal epithelial cells upon exogenous lipid challenge. Notably, silencing of dGrasp in Drosophila caused similar defects of lipid accumulation in the midgut. These results highlight the importance of the Golgi complex in cellular lipid regulation, which is evolutionary conserved, and uncover potential therapeutic targets for obesity-associated diseases.

Protein Engineering of an Improved Pair of Magnets Photodimerizer Proteins, and Their Use to Rapidly and Locally Reconstitute VAP-dependent Interactions between the Endoplasmic Reticulum, Golgi, and Endosomes.

L. Benedetti[1], J. S. Marvin[2], L. L. Looger[2], P. De Camilli[1]; [1]Yale University School of Medicine, New Haven, CT, [2]HHMI Janelia Research Campus, Ashburn, VA.

A distinctive feature of eukaryotic cells is the partitioning of the cytoplasm into membrane-enclosed organelles to orchestrate and separate cellular processes. Organelles typically communicate with one another through vesicular transport or via direct membrane contacts. The VAMP-associated proteins (VAPs), comprising VAPA and VAPB, are tail-anchored ER membrane proteins that tether the ER to other membranes via interactions with membrane proteins in other organelles. VAPs contain: 1) a cytosolic N-terminal MSP domain, which binds proteins containing the so-called FFAT motif, 2) a coiled-coil region responsible for homo/heterodimerization, and 3) a C-terminal membrane anchor. VAP-driven ER-organelle contacts play a multiplicity of functions, including trafficking of phosphatidylinositol 4-phosphate (PI4P) from other organelles to the ER for degradation by the phosphatidylinositol phosphatase enzyme Sac1. This transport activity is mediated by oxysterol-binding protein-related proteins (ORPs) that bind VAP via an FFAT motif and other membranes via a PH domain. Accordingly, HeLa cells lacking VAP exhibit several defects, including abnormally high accumulation of PI4P in the Golgi complex and endosomes. Detailed exploration of the role of VAP in cell physiology would benefit from the possibility of reversibly turning on and off its tethering function. To achieve this goal, we first engineered an improved blue light-dependent dimerization system starting from the charged-complementary dimerization pair of the LOV-domain Magnets proteins. Importantly, Magnets do not require exogenous cofactors, hetero- rather than homo-oligomerize, are very small (147 aa), can be fused to either terminus of a protein, are functional when tethered to intracellular membranes, and require simultaneous photoactivation to achieve dimerization, which enables high spatial confinement with a single wavelength of light. A serious drawback of Magnets for studies of mammalian cells, however, is their low temperature (28^{o}C) requirement for proper folding. To overcome this limitation, we engineered an improved Magnets pair that fold at mammalian physiological temperatures. We used this tool to rapidly and reversibly recruit of VAPB to the ER membrane in VAPA/VAPB double-knockout cells to acutely reconstitute VAP function. Exposure of these cells to blue light reduced PI4P accumulation on endosomes and Golgi within tens of seconds, validating the use of the improved Magnets to rapidly manipulate subcellular functions in mammalian cells with high temporal and spatial precision. This improved Magnets pair will be useful for creating many optogenetic reagents.

Loss of Lysosomal Npc1 Function Increases PtdIns4P to Sustain ER to Golgi Cholesterol Transfer.

O. Vivas, **C. Kutchukian**, M. Casas Prat, J. G. Jones, S. A. Tiscione, R. Dixon, E. J. Dickson; University of California, Davis, Davis, CA.

Cells utilize vesicular and non-vesicular transport mechanisms to transport lipids to target organelles. Non-vesicular lipid transport is mediated by transfer proteins that tether the gap between two closely apposed organelle membrane contact sites. At contact sites between Trans-Golgi network (TGN) and Endoplasmic reticulum (ER), oxysterol-binding protein (OSBP) mediates cholesterol/ PtdIns4P exchange. In health, TGN PtdIns4P is transported down its concentration gradient to ER, fueling the

countertransport cycle of cholesterol to TGN against its steep concentration gradient. Maintaining the PtdIns4P gradient and thus perpetuating this exchange cycle, are PtdIns4P kinases on the TGN and a PtdIns4P phosphatase (Sac1) on the ER. Consequently, this cholesterol/PtdIns4P exchange contributes to the establishment of a cholesterol gradient between organelles of the secretory pathway, essential for protein trafficking to the plasma membrane (PM). Despite this knowledge, little is known about how this molecular choreography is disrupted during pathophysiological conditions. In Niemann-Pick Type C1 (NPC1) disease, a pathological condition that leads to hyperexcitability and neurodegeneration, there is an alteration of lysosomal cholesterol homeostasis. Here we show that in models of NPC1 disease, there is a rearrangement of molecular components of the cholesterol/PtdIns4P cycle. Using a combination of mass-spectrometry, super-resolution imaging, and electrophysiology, we have discovered that inhibition or disease-causing mutations in the lysosomal transporter Niemann-Pick Type C1 result in a significant elevation in Golgi PtdIns4P. The increase in TGN PtdIns4P is not due to a slower rate of OSBP-mediated PtdIns4P transfer, or increased protein levels of PI4K isoforms. Instead, the increase in TGN PtdIns4P levels is due to spatial redistribution of PI4KIIα and PI4KIIIβ isoforms. Concurrent with the enhanced recruitment of PI4KIIIβ to the TGN is a significant accumulation of endogenous ER Sac1 at the contact site between the ER and TGN. The parallel reorganization of PI4KIIIβ and Sac1 ensures the maintenance of a steep PtdIns4P gradient that strengthens cholesterol transport to the Golgi. We also find that a downstream consequence for the increased cholesterol/ PtdIns4P exchange in NPC1 disease, is a dysregulation of vesicular trafficking of the AMPA Receptor Subunit GluA1. Physiologically, altered GluA1 subunit density at the PM aberrantly modifies the influx of calcium into neurons and may contribute to neuronal cell death in NPC1 disease. We propose that lysosomal NPC1-mediated cholesterol efflux modulates the molecular organization of TGN-ER contact sites to influence the driving force for cholesterol transport in health and disease.

P561/B574

The Interaction between Non-fusogenic Sec22b-syntaxin Complexes and Extended-synaptotagmins Promotes Neurite Growth and Ramification.

A. Gallo[1], F. Giordano[2], L. Danglot[1], T. Binz[3], C. Vannier[1], **T. Galli**[1]; [1]IPNP, INSERM U1266, Paris, FRANCE, [2]I2BC, CNRS, INSERM, Gif-sur-Yvette, FRANCE, [3]Institut für Zellbiochemie, OE4310, Hannover, GERMANY.

Axons and dendrites are long and often ramified neurites that need particularly intense plasma membrane expansion during the development of the nervous system. Neurite growth depends on non-fusogenic Sec22b-Syntaxin1 SNARE complexes at endoplasmic reticulum (ER)-plasma membrane (PM) contacts. Here we show that Sec22b interacts with the endoplasmic reticulum lipid transfer proteins Extended-Synaptotagmins (E-Syts) and this interaction depends on the Longin domain of Sec22b. Overexpression of E-Syts stabilizes Sec22b-Stx association, whereas silencing of E-Syts has the opposite effect. Overexpression of wild-type E-Syt2, but not mutants unable to transfer lipids or attach to the ER, increase the formation of axonal filopodia and ramification of neurites in developing neurons. This effect is inhibited by a clostridial neurotoxin cleaving Stx1, expression of Sec22b Longin domain and a Sec22b mutant with extended linker between SNARE and transmembrane domains. We conclude that Sec22b-Stx1 ER-PM contact sites contribute to PM expansion by interacting with E-Syts.

Phosphatidylinositol-4,5-bisphosphateRegeneration during Muscarinic Receptor 1 Stimulation.

J. Myeong, D. Ko, B. Hille; Physiology and Biophyics, University of Washington, seattle, WA.

Phosphatidylinositol 4,5-bisphosphate (PtdIns[4,5]P_2) participate many cellular functions. For example, regulation of ion channels, regulation of endo-, exocytosis, and precursor of Inositol-1,4,5-triphosphate (Ins(1,4,5)P_3) and diacylglycerol (DAG). With G alpha q protein-coupled receptor (GqPCR) expressed cells, phosphatidylinositol 4-phosphate (PtdIns4*P*) and PtdIns[4,5]P_2 are depleted in ~ 20 s by Oxotremorin (Oxo-M), but if we leave the agonist on continuously for 10 min, the PtdIns[4,5]P_2 is recovered. Indicator of Ins(1,4,5)P_3 and DAG, products of PtdIns[4,5]P_2 hydrolysis, increased continuously in stimulation of GqPCR. Additionally, by the mathematical computer model, we found acceleration of PtdIns[4,5]P_2 regeneration model is matched with actual data. As a results, PtdIns[4,5]P_2 regeneration is accelerated during GqPCR stimulation. PtdIns4*P* is a precursor of PtdIns[4,5]P_2. Therefore PtdIns 4-kinases, enzymes that phosphorylate Phosphatidylinositol (PtdIns) to PtdIns4*P*, are key molecules for regeneration. When we blocked PtdIns 4-kinases by pharmacological method, we found *PI4KA* (PI4KIIIα) is a key enzyme to PtdIns[4,5]P_2 recovery. Additionally, the Golgi PtdIns4*P* is major contributor for regeneration of PtdIns[4,5]P_2, not membrane PtdIns4*P*

Yeast Phosphatidylinositol Transfer Proteins Pdr16 and Pdr17: Similar, Yet Different.

D. Tahotná[1], R. Holič[1], N. J. Blunsom[2], V. Kotrasová[3], K. Ardanová[1], L. Pokorná[1], Z. Pevalová[3], J. A. Bauer[3], V. Pevala[3], E. Kutejová[3], S. Cockcroft[2], **P. Griac**[1]; [1]Centre of Biosciences, Slovak Academy of Sciences, Bratislava, SLOVAKIA, [2]University College London, London, UNITED KINGDOM, [3]Institute of Molecular Biology, Slovak Academy of Sciences, Bratislava, SLOVAKIA.

The yeast *Saccharomyces cerevisiae* possess 6 proteins classified as phosphatidylinositol transfer proteins (PITPs). Two of the yeast PITPs, Pdr16p (also called Sfh3p) and Pdr17p (also known as Sfh4p, PstB2p or Iss1p) are 49% identical and 75% similar. Pdr16p regulates lipid droplet utilization, clearance of cytosolic inclusion bodies, and is required for resistance to azole antifungals. Pdr17p is an essential component of a complex required for transport of phosphatidylserine (PS) between the ER and the Golgi apparatus/endosomes. To study the function of these two proteins in more detail we examined the role of phosphatidylinositol binding by these lipid transfer proteins. We also investigated the role of Pdr17p in PS transfer between the ER and the Golgi apparatus/endosomes using random mutagenesis approach. We found, using Pdr16p and Pdr17p mutants defective in PI binding, that for the proper function of Pdr16p in ensuring resistance to azole antifungals both high affinity PI binding and the ability to transfer PI between membranes must be retained. In contrast, Pdr17p high affinity PI binding is dispensable for Pdr17p function in a complex that is required to transfer PS from the ER to the Golgi apparatus/endosomes. We observed that PI binding defective Pdr17p mutant is not able to complement a defective Sec14p or a missing Pdr16p. This feature enabled the preparation of Pdr17^{Ser174Pro} mutant specifically defective in PS transfer from the ER to the non-mitochondrial site of PS decarboxylation. This mutant is defective in this process most likely due to its inability to interact with PS decarboxylase 2. Our results provide evidence that Pdr16p fulfills role(s) in which the ability to bind and transfer PI is required. In contrast, Pdr17p adapted to a different role which does not require high affinity PI binding, although the protein retains the capacity to transfer PI in *vitro.* Importantly, Pdr16p and Pdr17p bind also cholesterol in addition to PI in an assay using permeabilized HL-60 cells. Our results underscore the need

to follow multiple parameters of lipid transfer proteins when studying these proteins. This research was supported by the Scientific Grant Agency of the Ministry of Education, Science, Research and Sport of the Slovak Republic and the SAS grant 2/0111/15, the Slovak Research and Development Agency contract No. APVV-15-0654, and the British Heart Foundation grant FS/15/73/31672.

Insulin Controls Kinesin-dependent an terograde Transport of Lipid Droplets to Release Triglycerides from Liver.

M. Kumar[1], S. Ojha[1], P. Rai[1], S. S. Kamat[2], R. Mallik[1]; [1]Tata Institute of Fundamental Research, Mumbai, INDIA, [2]Indian Institute of Science Education and Research, Pune, INDIA.

Despite massive fluctuations in its internal triglyceride content, liver continues to secrete triglyceride under tight homeostatic control. This fine-tuned lipid homeostasis is most evident during fasting as triglyceride level increases by many folds in the liver, but serum triglyceride levels barely fluctuate. Unfortunately, the molecular mechanism underlying this lipid homeostasis in the liver remain largely unclear. Moreover, this buffering ability of the liver is essential to prevent systemic hyperlipidemia across our daily feeding-fasting cycles. We have uncovered a novel cellular mechanism involved in regulating triglyceride secretion from the liver across feeding-fasting cycles. A molecular interplay between a key metabolic-hormone (Insulin), the smallest phospholipid (phosphatidic acid, PA) and a molecular motor (kinesin-1) maintains triglyceride homeostasis in the liver. In fed state, insulin activates ARF1-GTPase on lipid droplets (LDs, triglyceride depot) that generate reactive LDs and also recruits phospholipase D1 (PLD1) on its membrane. The recruited PLD1 hydrolyses phosphatidylcholine (PC) into PA, which in turn recruits Kinesin-1 motor protein on LDs and translocated them to cortically located smooth endoplasmic reticulum (sER). The LD-sER contacts at the cell periphery ensure the delivery of LD-triglycerides to the lumen of sER for lipo-protein (VLDL) assembly. During fasting *i.e*. In absence of insulin signal, this entire pathway is downregulated and the triglyceride secretion is tempered to maintain the serum triglyceride level constant. Pharmaceutical or molecular inhibition of this pathway at multiple levels, results in slow release of triglycerides from hepatocytes. A targeted peptide-based cell-therapy also diminishes triglyceride secretion from hepatocytes without any apparent effect on intracellular organelle distribution and cell viability. In a nutshell, our work revealed a fundamental cellular mechanism to establish systemic lipid homeostasis and multiple molecular targets against hyperlipidemia like lipid-centric disorders. **References:** Kumar M, Ojha S, Rai P, Joshi A, Kamat S S and Mallik R. 2019. Insulin activates Intracellular transport of Lipid Droplets to release Triglyceride from the Liver. *Journal of Cell Biology*. Some Lipid Droplet Biogenesis Does Not Require Seipin Or Fat Storage-inducing Transmembrane (fitm2) Proteins.

K. K. Yadav[1], M. R. Molenaar[2], A. Toulmay[1], M. C. Mari[3], F. Reggiori[3], B. Helms[2], W. A. Prinz[1]; [1]National Institute of Diabetes and Digestive and Kidney Diseases, NIH, Bethesda, MD, 208992, MD, [2]Department of Biochemistry and Cell Biology, Faculty of Veterinary Medicine, Utrecht University, 3584 CM, Utrecht, NETHERLANDS, [3]Department of Cell Biology, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS.

Lipid droplets (LDs) are ubiquitous lipid storage organelles that play critical roles in lipid homeostasis. LDs are made up of a core of neutral lipids, primarily triacylglycerols (TAGs), and sterol esters (SEs), surrounded by a phospholipid monolayer. Other neutral lipids, such as retinyl esters, can also be stored in LDs. LD biogenesis occurs in the ER, where neutral lipids are synthesized, but the mechanism is not well understood. We investigated how the type of neutral lipid stored in LDs affects biogenesis. We generated a *S. cerevisiae* strain that cannot produce endogenous neutral lipids (TAGs and SEs) and instead produces retinyl esters. These cells produced LDs that contain only retinyl esters and the LDs are indistinguishable, by electron microscopy, from endogenous LDs. We next investigated whether proteins known to play roles in endogenous LD biogenesis are also necessary for generation of retinyl ester LDs. We found that retinyl ester LD biogenesis does not require seipin or fat storage-inducing transmembrane protein 2 (FITM2) proteins, unlike endogenous LDs. Our findings suggest that these proteins are necessary for the biogenesis of LDs that contain primarily TAGs but not LDs containing other neutral lipids.

P566/B579

Drosophila Adipocytes Organize Their Lipid Droplets into Spatially and Functionally Distinct Subpopulations.

J. Bowerman[1], R. Ugrankar[1], H. Hariri[1], B. Collins[2], S. Jean[3], M. Henne[1]; [1]UT Southwestern Medical Center, Dallas, TX, [2]University of Queensland, St. Lucia, AUSTRALIA, [3]University of Sherbrooke, Sherbrooke, QC, CANADA.

Adipocytes store nutrients as lipid droplets (LDs), but how they organize their LD stores to balance lipid uptake, storage, and mobilization remains poorly understood. Here, using Drosophila fat body (FB) adipocytes we characterize spatially distinct LD populations that are maintained by different lipid pools. We identify peripheral LDs (pLDs) that make close contact with the plasma membrane (PM) and are maintained by lipophorin-dependent lipid trafficking. pLDs are distinct from larger cytoplasmic medial LDs (mLDs) which are maintained by FASN1-dependent de novo lipogenesis. We find that sorting nexin CG1514/Snazarus (Snz) associates with pLDs and regulates LD homeostasis at ER-PM contact sites. Loss of SNZ perturbs pLD organization whereas Snz over-expression drives LD expansion, triacylglyceride production, starvation resistance, and lifespan extension through a DESAT1-dependent pathway. We propose that Drosophila adipocytes maintain spatially distinct LD populations and identify Snz as a novel regulator of LD organization and inter-organelle crosstalk.

Kinases and phosphatases 1

Defining How Cdr1/nim1 Inhibits Wee1.

H. Opalko[1], I. Nasa[1,2], A. Kettenbach[1,2], J. B. Moseley[1]; [1]Dartmouth College, Hanover, NH, [2]Norris Cotton Cancer Center, Lebanon, NH.

Entry into mitosis initiates from a switch-like activation of cyclin-dependent kinase (Cdk1). During interphase, the conserved protein kinase Wee1 phosphorylates and inhibits Cdk1 until cells have grown to a critical size threshold. To enter into mitosis, cells require mechanisms that inhibit Wee1 and allow activation of Cdk1. In fission yeast, the related protein kinases Cdr1/Nim1 and Cdr2 act as upstream inhibitors of Wee1. Several questions have remained open regarding when, where, and how Cdr1/Nim1 and Cdr2 inhibit Wee1 in cells. Past work found that Cdr1/Nim1 phosphorylates Wee1 to inhibit its kinase activity (1-3). We found that both Cdr1/Nim1 and Cdr2 induced hyperphosphorylation of Wee1, but only Cdr1/Nim1 inhibited Wee1 kinase activity. Using both purified proteins and co-expression, we found that Cdr1/Nim1 phosphorylated a cluster of residues within the C-terminal lobe of the Wee1 kinase domain. Mutations that prevent phosphorylation of these sites caused cells to divide at a larger size and to exhibit synthetic lethality with *cdc25* mutations, consistent with overactive Wee1. Further, this inhibitory phosphorylation altered the balance of Wee1-Cdk1 reciprocal regulation to alter cell size at division. Our work provides mechanistic insight into the control system that links Wee1 activity with cell size and nutrient conditions. 1. Coleman, T. R., Tang, Z., and Dunphy, W. G. Cell Size Is Regulated by Phosphatidylinositol 3-phosphate in *Drosophila*.

A. Ghosh, D. Shinde, P. Raghu; National Centre for Biological Sciences, Bangalore, INDIA.

Regulation of cell size is a key aspect of growth and development in metazoans. Growth control requires the integration of nutritional and hormonal cues and many of these are transduced by mTORC1 through its output S6K kinase, an essential modulator of protein synthesis and cell growth. It is reported that in *Drosophila*, phosphatidylinositol 5 phosphate 4-kinase (dPIP4K) regulates mTORC1 activity and cell growth. In *Drosophila* PIP4K mutants (*dPIP4K*^{29}), both mTORC1 activity and cell size are reduced. dPIP4K can phosphorylate both phosphatidylinositol 5-phosphate (PI5P) and phosphatidylinositol 3-phosphate (PI3P). It has previously been reported that PI5P levels are elevated in *dPIP4K*^{29}. We now report by LC-MS measurements that PI3P levels are also elevated in these mutants raising the possibility that elevations in PI3P may also regulate mTORC1 and cell growth. Consistent with this idea, overexpression of Vps34, a class III PI3Kinase that generates PI3P, reduces *Drosophila* salivary gland cell size and the co-expression of Myotubularin (dMtm), a PI3P 3-phosphatase that can reduce PI3P levels is able to rescue this reduced cell size. Finally, we found that overexpression of dMtm in *dPIP4K*^{29} was able to reverse both the reduced cell size as well as elevated PI3P levels. Our work defines PI3P acting via dPIP4K as a novel regulator of cell size.

Phosphoproteomic an alysis of the Mammalian Growth Cones Reveals the Novel Molecular Markers of the Growing/regenerating Axons, Specifically to Vertebrate.

M. Igarashi, Y. Ishikawa, S. Okuda; Niigata University, Sch Ned & Grad Sch Med Dent Sci, Niigata, JAPAN.

The growth cone is an essential structure formed in the developing axons for accurate neuronal network formation. However, in the mammalian growth cone behavior, these problems are poorly approached so far. We focused the phosphorylation which is the most important protein modification in the cellular signaling pathways, and performed the phosphoproteomic analysis of the growth cone membrane (GCM) prepared from the developing rodent brain, to comprehensively know the phosphorylation sites and their frequency for neuronal development. We identified 30,000 phosphopeptides derived from the 5,000 phosphorylation sites of 1,200 proteins. We have already found GAP-43, a vertebrate-specific neuronal protein, has a highly phosphorylated residue Ser96, and showed this phosphorylation as a growing/regenerating marker of axon (ref.1). In this study, we also featured two of the most abundant phosphorylated sites, Ser25 and Ser1201 of microtubule-associated protein 1B (MAP1B), which is a protein known to stabilize axonal microtubules and to be involved in axon formation. We produced the phospho-specific antibodies (Abs) against these sites, respectively, which preferentially labelled the growing axons in the embryonic brain. In the injured sciatic nerve, we found that the immunoreactivity of each Ab was increased at the injury site and extended to the distal side over the injured point. A considerably large amounts of these sites were phosphorylated by the proline-directed protein kinases such as JNK, which is known to be involved in axon growth within a wide range of animals from *C. elegans* or *Drosophila* to mammals. Bioinformatic analysis revealed that most of these sites were conserved within the vertebrates, however, were not conserved in simpler model organisms such *C. elegans* or *Drosophila*. In particular, most of the highly frequent phosphorylation sites (more than 20 times) in GCM were not conserved in *C. elegans* or *Drosophila*. We concluded that the mammalian signaling pathways in GCM are totally distinct from the model organisms.

P570/B584

Phosphatidylinositol Kinases and Phosphatases in the Enteric Protozoan Parasite *Entamoeba Histolytica*.

K. Nakada-Tsukui[1], N. Watanabe[2], T. Maehama[3], T. Nozaki[4]; [1]Department of Parasitology, National Institute of Infectious Diseases, Tokyo, JAPAN, [2]Graduate School of Life and Environmental Sciences, University of Tsukuba, Ibaraki, JAPAN, [3]Division of Molecular and Cellular Biology, Graduate School of Medicine, Kobe University, Hyogo, JAPAN, [4]Department of Biomedical Chemistry, Graduate School of Medicine, the University of Tokyo, Tokyo, JAPAN.

Phosphatidylinositol (PtdIns) metabolism is indispensable in eukaryotes. Phosphoinositides (PIs) are phosphorylated derivatives of PtdIns and consist of seven species generated by reversible phosphorylation of the inositol moieties at the positions 3, 4, and 5. Each of the seven PIs has a unique subcellular and membrane domain distribution. In the enteric protozoan parasite *Entamoeba histolytica*, it has been previously shown that the PIs, phosphatidylinositol 3-phosphate (PtdIns3P), PtdIns(4,5)P_2, and PtdIns(3,4,5)P_3 are localized to phagosomes/phagocytic cups, plasma membrane, and phagocytic cups, respectively. The localization of these PIs in *E. histolytica* is similar to that in mammalian cells, suggesting that PIs have orthologous functions in *E. histolytica*. In contrast, the conservation of the

enzymes that metabolize PIs in this organism has not been well documented. Here, we report the full repertoire of the PI kinases and PI phosphatases found in *E. histolytica* via a genome-wide survey of the current genomic information. *E. histolytica* appears to have 10 PI kinases and 23 PI phosphatases. It has a panel of evolutionarily conserved enzymes that generate all the seven PI species. However, class II PI 3-kinases, type II PI 4-kinases, type III PI 5-phosphatases, and PI 4P-specific phosphatases are not present. Additionally, regulatory subunits of class I PI 3-kinases and PI 4-kinases have not been identified. Instead, homologs of class I PI 3-kinases and PTEN, a PI 3-phosphatase, exist as multiple isoforms, which likely reflects that elaborate signaling cascades mediated by PtdIns(3,4,5)P_3 are present in this organism. There are several enzymes that have the nuclear localization signal: one phosphatidylinositol phosphate (PIP) kinase, two PI 3-phosphatases, and one PI 5-phosphatase; this suggests that PI metabolism also has conserved roles related to nuclear functions in *E. histolytica*, as it does in model organisms.

P571/B585

Cyclic GMP-dependent Kinase Triggers Cytosolic Calcium Signaling in the Human Malaria Parasite *Plasmodium Falciparum*.

M. K. Singh[1,2], P. Bartlett[2], A. P. Thomas[2], C. R. S. Garcia[1]; [1]Department of Clinical and Toxicological an alyses, School of Pharmaceutical Sciences, University of Sao Paulo, São Paulo, BRAZIL, [2]Department of Pharmacology, Physiology & Neuroscience, New Jersey Medical School, Newark, NJ.

Malaria is accountable for the death of more than 400,000 people across the continents in tropical and sub-tropical regions. The responsible pathogens belong to the *Plasmodium spp. Of* apicomplexan protozoa and among them; *P. falciparum* is the most virulent with the highest fatalities. The clinical symptoms of malaria are associated with the periodic rupture and exponential increase of parasites in the host circulation system where it uses the sequential discharge of the apical proteins in a complex signaling cascade to maintain the growth and transmission. The discharge trigger is shown to initiate by the secondary messengers and protein kinase activation. Here in this study, we used a genetic calcium marker parasite expressing PfGCamP3 to study the calcium efflux in the asexual trophozoite parasites that were intact in their natural red blood cell host. We found that inhibiting the *P. falciparum* phosphodiesterase by zaprinast induce transient calcium release from the parasite calcium store. We observed that the zaprinast induced calcium rise was abolished in cyclopiazonic acid (CPA) pretreatment, suggesting a common source. The calcium signal is specific to cGMP, as stimulating with a cell-permeant analog 8Br-cGMP abrogates the zaprinast-induced calcium response and vice-versa in *P. falciparum* parasites. When we chelate the cytosolic calcium with BAPTA-AM, zaprinast was unable to elevate cytosolic calcium indicated the possible flux from the inner source. Interestingly, zaprinast induced calcium rise was also blocked in the presence of a protein kinase G (PKG) inhibitor compound-1. To find out the further downstream sequence, we used a phospholipase C (PLC) inhibitor, which interrupted the calcium efflux upon zaprinast induction strongly indicating the PLC-IP_3 mediated calcium release, however, no canonical IP_3-receptor is identified in the *P. falciparum* although pharmacological pieces of evidence are encouraging. Further, we found the direct link of PKG mediated IP_3-induced calcium rise when the parasites were treated with the IP_3 receptor antagonist 2-ABP, where zaprinast was unable to elicit calcium flux. It will be interesting to understand the complex cross-talk of other messengers such as cAMP that also plays a crucial role in regulating the calcium level to control microneme secretion during parasite invasion. Identifying the trigger of PKG to activate the downstream

calcium efflux may likely be proven a novel therapeutic candidate considering the divergence from their mammalian counterpart.

P572/B586

An Autocrine Negative Feedback Loop Inhibits *D. Discoideum* Proliferation through a Plc/ip3/ca^{2+} Pathway.

Y. Tang, R. Gomer; Texas A&M University, College Station, TX.

Very little is understood about how tissues can regulate their size. In one possible mechanism, cells in a tissue secrete a factor that inhibits their proliferation, and as the tissue gets bigger, the concentration of the factor increases. If the factor inhibits proliferation at some concentration, the resulting negative feedback loop will limit tissue size. Despite evidence for such factors, they have in general not been identified and thus their signal transduction pathways are unknown. We previously found that *Dictyostelium discoideum* accumulates extracellular polyphosphate to inhibit its proliferation. Polyphosphate inhibits the proliferation of *D. discoideum*, and this requires the G protein coupled receptor GrlD and the small GTPase RasC. To elucidate additional signaling components in the polyphosphate pathway, we screened 47 available signal transduction pathway mutants for insensitivity to polyphosphate. We found that cells lacking the G protein components Gβ and Gα3, the Ras guanine nucleotide exchange factor GefA, Phosphatase and tensin homolog (PTEN), Phospholipase C (PLC, which produces IP3 from PIP2), Inositol 1,4,5-trisphosphate receptor-like protein a (IplA, which acts as a calcium channel activated by IP3), Polyphosphate kinase 1(Ppk1), Growth-differentiation transition family members 1 and 2, Protein kinase A, or PiaA (cytosolic regulator of adenylate cyclase) showed a significantly reduced sensitivity to polyphosphate induced proliferation inhibition. In support of PLC being in the pathway, polyphosphate upregulates IP3, and this requires GrlD and PLC, and in support of IplA being in the pathway, polyphosphate upregulates cytosolic Ca^{2+}, and this requires GrlD, PLC, Ppk1 and IplA. These data suggest that polyphosphate inhibits the proliferation of *D. discoideum* through a PLC/IP3/Ca^{2+} pathway.

Elevated Phosphate Induces Extensive Cellular Injuries.

P. He, O. Mann, J. Fling, M. S. Razzaque; Lake Erie College of Osteopathic Medicine, Erie, PA.

Phosphate (PO_4) is an essential nutrient for human body health. It maintains and modulates normal cell functions. Insufficient intake of dietary phosphate may lead to an impaired bone development, whereas phosphate overload may cause cardiovascular calcification and premature ageing. In *vivo*, organic phosphate compounds are metabolized to inorganic phosphate in the form of dihydrogen phosphate (H_2PO_4) and monohydrogen phosphate (HPO_4). Our study focuses on inorganic phosphate's (Pi) extraskeletal effects. Evidence has shown that abnormal high level of Pi could promote cell growth and proliferation, indicating its potential role in carcinogenesis. In cancers, an increase of Pi is believed to be associated with cancer metastasis. Conversely, some studies have demonstrated that excessive Pi can kill cells and cause massive tissue damage. Most of these reported studies are confined to the phenotype description. The underlying molecular mechanisms remain unclear. Here we applied an increased amount of Pi (H_2PO_4) to mammalian cells for different durations. Cell viability/proliferation was tested by XTT assay. Furthermore, Pi perturbed cell signaling networks were explored by Western

blot analysis. We found that Pi triggers diverse cellular responses in a dose-dependent manner. At moderately higher (1mM-10mM) than physiological level, extracellular Pi could promote cell growth and survival by activating PI3K/AKT and MAPK signaling pathways. By introducing additional Pi (20-40mM), we observed significant cell injury. It was caused by interweaved Pi related biological events, including activation of MAPK signaling, ER stress, autophagy, and programmed cell death. The corresponding inhibitors or enhancers for each event were adopted to study the connections and dependency among the pathways. Beyond that, we found excessive Pi could enhance epithelial-mesenchymal transition (EMT) by inducing the EMT markers (such as increase level of phosphorylated Smad2 and Snail1, decreased expression of ZO-1) in cancer cells. This suggests the elevated extracellular Pi could promote tumor progression. Taken together, excessive extracellular phosphate causes a broad spectrum of toxicity in *vitro* by perturbing complicated signaling networks that control the cell growth, cell death, ER stress, autophagy, and cell mobility. Our results form the basis of further studies on other cell-based and mice models to deepen the understanding of phosphate induced cellular responses, and to provide therapeutic clues to minimize phosphate toxicity-associated clinical complications.

P573/B587

New Pathways That Regulate Myosin Light Chain Kinase and Cellular Force Development.

M. Eto[1,2], T. Matsui[1], K. Takeya[1], K. Akagi[3], S. Katsuki[1], N. Hatano[3], H. Tokumitsu[3], T. Kitazawa[2]; [1]Faculty of Veterinary Medicine, Okayama University of Science, Imabari, JAPAN, [2]Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA, [3]Graduate School of Interdisciplinary Science and Engineering in Health Systems, Okayama University, Okayama, JAPAN.

Reversible phosphorylation of myosin light chain governs cellular force development. The binding affinity of Ca^{2+} to calmodulin defines Ca^{2+} sensitivity of the force development. In addition, the Ca^{2+} sensitivity is also reported to fluctuate in response to stimuli and contribute to the regulation of myosin light chain phosphorylation. Here, we found evidence that, in phasic smooth muscle tissues, such as intestines and urinary bladder, the Ca^{2+}-sensitivity of myosin light chain kinase (MLCK) declines after reaching at the peak force. Longitudinal smooth muscle tissues from mouse ileum were set to force transducers and subjected to partial permeabilization using beta-escin. The permeabilized tissues were relaxed in the solution with 1 mM EGTA and then stimulated with a sub maximum [Ca^{2+}] of pCa6.0 (1.0 μM). Upon the stimulation, the contraction and myosin light chain phosphorylation peaked within 30 sec and then declined to 50% of maximum level at 2 min after stimulation. The reduction in the myosin light chain phosphorylation at the clamped [Ca^{2+}] indicates the Ca^{2+}-induced Ca^{2+}-desensitization. MLCK activity in the permeabilized tissues increased by 30 sec, and then declined at 3 min after stimulation, whereas MLCP activity was unchanged at any time points in the tissue. Thus, the fluctuation in MLCK activity at clumped [Ca^{2+}] is likely a cause of the Ca^{2+}-induced Ca^{2+}-desensitization. The Ca^{2+}-induced MLCK desensitization was associated with phosphorylation at the calmodulin binding domain of the kinase. Data of pharmacological experiments using kinase antagonists suggest that unknown pathway(s) but not CaMKII, CaMKIV or AMPK are responsible for the temporal MLCK inactivation. In addition, pretreatment of the tissues with rubratoxin a potentiated the MLCK inactivation suggesting an involvement of PP2A. Novel pathways for reversible MLCK phosphorylation may define the force development in phasic smooth muscles. This work is supported by funds from Imabari city and Ehime Prefecture.

Ras and Cell Migration: a Rsky Signal to Myosin Phosphatase.

M. C. Mendoza, S. C. Samson, K. Carney, J. Bergman; University of Utah, Salt Lake City, UT.

Cell migration is essential to embryonic development, wound healing, and cancer cell dissemination. Cells move via leading-edge protrusion, substrate adhesion, and retraction of the cell's rear. The molecular mechanisms by which extracellular cues impinge the actomyosin cytoskeleton to control these motility mechanics are poorly understood. The growth factor-responsive and oncogenically activated protein extracellular signal-regulated kinase (ERK) promotes motility by signaling in actin polymerization-mediated edge protrusion. It has long been known that ERK can signal to activate myosin II. While a direct signal to myosin light chain kinase (MYLK) has been proposed, optimal and conserved ERK phospho-motifs are not found in MYLK. We sought to uncover the signaling mechanism by which ERK modulates myosin during cell migration. Using a combination of biochemistry and live-cell imaging, we show that ERK signals to the contractile machinery through its substrate, p90 ribosomal S6 kinase (RSK). We probed the signaling and migration dynamics of multiple mammalian cell lines and found that RSK phosphorylates myosin phosphatase-targeting subunit 1 (MYPT1) at Ser-507, which promotes an interaction of Rho kinase (ROCK) with MYPT1 and inhibits myosin targeting. We find that by inhibiting the myosin phosphatase, ERK and RSK promote myosin II-mediated tension for lamella expansion and optimal edge dynamics for cell migration. These findings suggest that ERK activity can coordinately amplify both protrusive and contractile forces for optimal cell motility.

P576/B590

Dsk1 Protein Kinase Plays a Role in Cellular Response to Stress.

A. V. Freitas[1], A. Vyas[2], Z. Tang[2]; [1]Pitzer College, Claremont, CA, [2]W. M. Keck Science Department, the Claremont Colleges, Claremont, CA.

mRNA metabolic processes including pre-mRNA processing, and mature mRNA export, localization, and degradation constitute an integral aspect of gene expression and regulation. SR (serine/arginine-rich) protein kinases have a vital role in gene expression through the regulation of pre-mRNA splicing factors. The two SR protein kinases, Dis1-suppressing protein kinase (Dsk1) and Kinase in the Clk/Sty family1 (Kic1), are the *Schizosaccharomyces pombe* functional orthologs of human SRPK1 and mouse Clk1/Sty1, respectively. Prior research has demonstrated the importance of Dsk1 and Kic1 in mRNA splicing. Furthermore, nuclear retention of intron-less mRNA in Dsk1- and Kic1-null cells suggest these protein kinases also have a role in mRNA nuclear export, discrete from their role in splicing. Additionally, our lab had previously co-purified Dsk1 with major poly(A) binding protein (Pabp), an mRNA export protein that shuttles mRNA from the nucleus to the cytoplasm. We hypothesize that Dsk1 and Kic1 act on Pabp to facilitate mature mRNA export. PCR-based in *vivo* gene targeting was used to GFP tag Pabp and the related Poly(A)-binding protein 2 (Pab2) at their genomic loci in Δ*dsk1* and Δ*kic1* background strains of *S. pombe*, as well as in the two control strains: wild-type and Δ*srp1. The* effect of Dsk1 and Kic1 kinases on PabpGFP and/or Pab2GFP localization was visualized using fluorescent microscopy. We found that higher temperature promotes the formation of Pabp containing cytoplasmic foci, or stress granules, in the cells lacking Dsk1 kinase, but not in Δ*kic1* and Δ*srp1* mutants when compared to the wild-type cells. It has been posited that these stress granules are evolutionarily conserved structures, formed as a result of stress-induced polysome disassembly. The results suggest that Dsk1 is involved in *S. pombe* response to stress. It will be interesting to determine if Dsk1 or Kic1 alters the level of Pabp phosphorylation. As

Dsk1 and Kic1 are highly conserved in eukaryotes, our findings in *S. pombe* may elucidate the role of SR protein kinases in the regulation of mRNA metabolic processes in other complex eukaryotes, including humans.

P577/B591

The DSP Domain of MK-STYX in Decreasing Stress Granules.

F. Jiang; College of William and Mary, Williamsburg, VA.

The DSP domain of MK-STYX in Decreases Stress Granules Fei (Krystal) Jiang and Shantá D. Hinton Department of Biology, Integrated Science Center, William and Mary, Williamsburg, VA 23187 MK-STYX [MAPK (mitogen activated protein kinase) phosphoserine/threonine/tyrosine binding protein] is a pseudophosphatase. Due to point mutations in the HC(X5)R catalytic active site signature motif, MK-STYX (FSTQGISR) can only bind, but cannot dephosphorylate phosphorylated residues. This interaction of MK-STYX allows it to play important roles in various cellular pathways including the stress response pathway. MK-STYX decreases stress granules (SG) independently of serine 149 phosphorylation of G3BP-1 (stress granule nucleator). Stress granules are cytoplasmic aggregates of untranslated mRNA and proteins formed in response to stressors. The aim of this study is to determine which domain of MK-STYX decreases stress granules. MK-STYX has two domains: a dual specificity phosphatase domain (DSP) and a rhodanese/cdc 25 phosphatase homology domain. In our study, HEK-293 cells cotransfected with G3BP-GFP and mCherry-DSP, mCherry-MK-STYX-CH2, or mChrerry. Cells expressing G3BP-GFP and mCherry-MK-STYX-DSP exhibit fewer SG than the control (G3BP-GFP and mCherry. Whereas, cells cotransfected with G3BP-GFP and mCherry-CH2 have similar levels of SG compared to the control, indicating that the DSP domain of MK-STYX is responsible for decreasing the number of stress granules. Since the “active site” lies within the DSP domain, the study suggests that MK-STYX decreases SG by binding, and perhaps blocking dephosphorylation of certain proteins. Future studies will focus on characterizing (size and exact number of these SG, as well as the interactors of MK-STYX-DSP.

P578/B592

Uhmk1 Knockdown Impacts the Expression of Epithelial-Mesenchymal Transition Genes in NIH3T3 Cells.

V. C. Arfelli[1], P. Kerbs[2], E. Redondo Monte[2], G. Leubolt[2], A. Wilding[2], Y. Chang[3], S. Heinzlmeir[3], B. Küster[3], P. A. Greif[2], L. F. Archangelo[1]; [1]University of São Paulo, Ribeirão Preto, BRAZIL, [2]Ludwig-Maximilians Universität München, Munich, GERMANY, [3]Technical University of Munich, Freising, GERMANY.

UHMK1 (U2AF Homology Motif Kinase 1, also known as KIS) is a kinase that interacts with and phosphorylates the splicing factors SF1 and SF3B1. These interactions point towards an important role of UHMK1 in RNA metabolism. It is known from the literature that UHMK1 participates in proliferation, migration, membrane trafficking, RNA local translation in neurons and differentiation. Our hypothesis is that UHMK1 could contribute to these and other cellular processes by regulating alternative splicing, gene expression and phosphorylation of the involved target proteins. In order to test Uhmk1 impact on gene expression, NIH3T3 cells were retrovirally-transduced to express Uhmk1 and Uhmk1-shRNA sequences. The Uhmk1-overexpressed and -knockdown cells were submitted to RNA-seq (adapted mcSCRB-seq) and subsequent differential expression analysis was performed by edgeR/limma package. A total of 32 genes was identified as differentially expressed in Uhmk1 knockdown (p-value <0.05). Among them, 17 genes were upregulated and 15 genes were downregulated, with a log2 fold change

ranging from 0.17 to 0.72 and 0.18 to 1.66, respectively. Uhmk1 was found to be downregulated, confirming the shRNA efficiency. Research in literature showed that the human homologs of many of these genes, such as OAZ1 (Ornithine Decarboxylase antizyme 1), PIMREG (PICALM-Interacting Mitotic Regulator), CDCA4 (Cell Division Cycle Associated 4), LOX (Lysyl Oxidase), MEMO1 (Mediator of cell Motility 1), TPT1 (Tumor Protein, Translationally-Controlled 1), MAP3K3 (Mitogen-Activated Protein Kinase Kinase Kinase 3) and PRRX1 (Paired Related Homeobox 1) are differentially expressed in tumors, and related to tumor progression and aggressiveness, proliferation, Epithelial-Mesenchymal Transition (EMT) and metastasis. Gene Set Enrichment an alysis (GSEA) showed EMT, receptor complex, protein complex disassembly and phospholipid binding among the most interesting pathways with a positive enrichment ($p<0.05$). Furthermore, phosphoproteome analysis was carried out, aiming to investigate the phosphorylated proteins under Uhmk1 regulation in a Uhmk1 overexpression and knockdown context. Preliminary data showed elevated phosphorylation of Sf1 at Serine 56 localized in the SPSP domain (D3YVH4_MOUSE, UniProt) in Uhmk1 knockdown. Splicing reporter assays and invasion experiments are ongoing to validate our findings. Based on our preliminary data, we suggest that UHMK1 could have a role in EMT by controlling the splicing of related genes.

P579/B593

Swi6 Localization to Heterochromatin Is Dependent on Dsk1 and Kic1 SR-protein Kinases.

Z. A. Ralston[1], A. Vyas[2], Z. Tang[2]; [1]Claremont Mckenna College, Claremont, CA, [2]W.M. Keck Science Department, the Claremont Colleges, Claremont, CA.

The Serine-Threonine (SR)-Protein kinases, namely, Kinase in the Clk/Sty family1 (Kic1) and Dis1-suppressing protein kinase (Dsk1) are important regulators of cellular pathways; such as cellular viability, differentiation and various aspects of development. The *Schizosaccharomyces pombe* Swi6 (human ortholog HP1) is a transcriptional heterochromatin binding protein that is recruited to heterochromatic regions, possibly as a result of phosphorylation by the protein kinases Kic1 and Dsk1. We hypothesize that phosphorylation of Swi6 by Dsk1 and/or Kic1, is responsible for Swi6 recruitment to heterochromatic regions in *S. pombe* cells. In this study, we investigated the change in localization of Swi6, in the protein kinase *Kic1 and Dsk1* deletion mutant strains. Using the technique of PCR-based GFP-tagging, Swi6 was endogenously tagged and Swi6-GFP localization was determined through fluorescence microscopy. Swi6 was visualized through examination of condensed dotted fluorescing structures within the nucleus, which potentially correspond to the heavily heterochromatic regions of DNA in telomeres and centromeres. In Wild Type (WT) cells, Swi6 is localized to the nucleus. It was found that upon deletion of the protein kinases Kic1 and Dsk1, distinct cytoplasmic Swi6-GFP localization was observed in both strains, which was not detected in wild-type *S. pombe* strains. The incubation temperature was varied between data collections at 30 and 36 degrees Celsius. In particular, the Kic1 36ºC cells had the highest amount of cytoplasmic Swi6-GFP localization, and similar levels of cytoplasmic localization was seen in the Kic1 30ºC strain, as well as the Dsk1 30ºC and Dsk1 36ºC strains. We are interested in further investigating the Swi6 phosphorylation status in these different genetic backgrounds through the immunoprecipitation of Swi6 followed by a Western blot analysis of the cellular extracts. The specific model of Swi6 phosphorylation can be determined through in *vitro* analysis of the purified proteins Kic1, Dsk1, and Swi6. Also, genetic mutagenesis of possible phosphorylation sites on Swi6 may be used to determine the specific locus of phosphorylation responsible for Swi6 recruitment to heterochromatin.

P580/B594

Systematic Mapping of the Human Calcineurin Signaling Network Uncovers a Novel Role for Calcineurin at the Nuclear Pore Complex.

C. P. Wigington[1], J. Roy[1], N. P. Damle[1], V. K. Yadav[2], C. Blikstad[2], E. Resch[3], C. J. Wong[4], D. R. Mackay[5], J. T. Wang[1], I. Krystkowiak[6], T. Stearns[1], A. Gingras[4], K. S. Ullman[5], Y. Ivarsson[2], N. E. Davey[7], M. S. Cyert[1]; [1]Stanford University, Stanford, CA, [2]Uppsala University, Uppsala, SWEDEN, [3]Fraunhofer Institute for Molecular Biology and Applied Ecology, Frankfurt am Main, GERMANY, [4]Lunenfeld-Tanenbaum Research Institute at Mount Sinai Hospital, University of Toronto, Toronto, ON, CANADA, [5]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, [6]Conway Institute of Oncological Sciences, University College Dublin, Dublin, IRELAND, [7]The Institute of Cancer Research, London, UNITED KINGDOM.

Protein phosphatases play essential roles in cell signaling; however, systems-level understanding of phosphatases is lacking due to challenges associated with identifying their substrates and regulators. Calcineurin (CN) is the conserved Ca^{2+}/calmodulin-activated protein phosphatase and target of the widely prescribed immunosuppressant drugs, FK506 and Cyclosporin A. CN is ubiquitously expressed and plays critical roles in the immune, nervous, skeletal and cardiovascular systems, as well as during development. CN utilizes conserved docking surfaces to recognize substrates via Short Linear Motifs (SLiMs) termed PxIxIT and LxVP, which occur preferentially in intrinsically disordered domains and are challenging to identify due to sequence degeneracy and low affinity for CN. We applied novel experimental and computational approaches to systematically identify CN-binding SLiMs in the human proteome and establish the human CN signaling network. In addition to significantly expanding our understanding of CN biology in human cells, these studies identified a novel and conserved role for CN at the nuclear pore - a structure where Ca^{2+} signaling is largely uncharacterized. Through our multi-pronged approach, we identified CN-binding SLiMs on multiple nucleoporins (Nups), specifically those involved in nuclear transport. Here, we show that CN binds to conserved PxIxIT motifs in Nup153, Nup50 and TPR - all three components of the nuclear basket structure. Furthermore, proximity ligation assays (PLAs) in HeLa cells demonstrate robust interaction between CN and nuclear basket components in *vivo*. Building upon published studies showing that ERK phosphorylates key transport Nups during viral infection, oxidative stress, and in various cancer cell lines, we show that CN opposes ERK phosphosites on multiple Nups in *vitro and* in *vivo*. Furthermore, we show that inhibition of CN in HeLa cells leads to the reduced rate and accumulation of an established nuclear transport reporter. Altogether, these studies suggest that CN positively regulates nuclear transport by opposing transport-inhibitory ERK phosphosites on key transport Nups. Consistent with our interest in this Ca^{2+}-activated enzyme, our future studies will focus on identifying cellular conditions that influence Ca^{2+}dynamics at the NPC.

Conserved Ndr Kinase Orb6 Regulates Cell Growth and Chronological Lifespan in Response to Environmental Stress.

C. Chen, P. Haller, M. Rodriguez Pino, **F. Verde**; University of Miami, Miami, FL.

Adaptation to the nutritional environment is critical for all cells. RAS GTPase is a highly conserved GTP binding protein with crucial functions for cell growth and differentiation in response to environmental conditions. Inappropriate activation of human RAS GTPase has a causal role in cancer, congenital malformations, and neurodevelopmental disorders. We previously found that the conserved NDR kinase Orb6 regulates the mRNA and protein levels of Ras1 guanine nucleotide exchange factor (GEF) Efc25, by

controlling the coalescence of the mRNA-binding protein Sts5 into ribonucleoprotein (RNP) granules (*Nuñez et al., Elife, 2016*). However, it is still unclear whether Orb6-Sts5 axis regulates RAS GTPase activity in response to the nutritional environment. Further, the molecular mechanisms by which Orb6 kinase controls Sts5 RNP coalescence are not characterized. Fission yeast *Schizosaccharomyces pombe*serves as a powerful model organism to study signaling pathways regulating nutrient sensing, cell growth, and morphogenesis due to its well-defined cell shape and growth pattern under nutrient variations. Using a phospho-specific antibody and an analog-sensitive *orb6-as2*strain, we can quantify the Orb6 kinase activity and the effect of Orb6 kinase inhibition. Here, we describe a novel mechanism tethering RAS GTPase to nutrient availability in fission yeast. The conserved NDR kinase Orb6 responds to nutritional cues and regulates Ras1 GTPase activity. Under nutrient-rich condition, Orb6 kinase increases the protein levels of a Ras1 GTPase activator, the guanine nucleotide exchange factor Efc25, by phosphorylating Serine 86 of Sts5, a protein bound to *efc25*mRNA. Under nutrient-depleted condition, Orb6 kinase activity decreases, leading to Sts5 RNP coalescence and decrease in Ras1 activity. By manipulating the extent of Orb6-mediated Sts5 coalescence into RNP granules, we can modulate Efc25 protein levels, Ras1 GTPase activity and as a result, cell growth and cell survival. The Orb6-Sts5-Ras1 regulatory axis plays a crucial role in promoting cell adaptation, balancing the opposing demands of promoting cell growth or extending chronological lifespan. Our findings highlight the conserved NDR kinase as a crucial enzyme in modulating cell growth and cell survival under favorable or adverse conditions, and in regulating cell adaptation and general stress response.

Effects of Polysubstituted Pyrroles on Pro-inflammatory Signaling in RAW264.7 Macrophages.

A. L. Wang, A. Mann, W. P. Black, M. M. Brown, J. T. Gupton, K. Fischer-Stenger; University of Richmond, Richmond, VA.

Inflammation protects against infection and restores the body to homeostasis after cellular and tissue damage from injury or metabolic stress. Complex signaling pathways are necessary for the activation of pro-inflammatory signaling in macrophages, and dysregulation of these pathways can contribute to disease states linked to chronic inflammation making them attractive targets for therapeutics. Our laboratory explores the potential of a class of polysubstituted pyrrole compounds that are known microtubule depolymerizers to regulate the inflammatory response in macrophages. Recent work from our laboratory demonstrated that JG-03-14 (3,5-dibromo-4-(3,4-dimethoxyphenyl)-1H-pyrrole-2-carboxylic_acid ethyl ester) and its refined analog, NT-07-16, which possesses an additional methoxy group at the 2-position of the phenyl ring, decrease the production of pro-inflammatory cytokines in lipopolysaccharide (LPS)-activated RAW264.7 macrophages. The reduction in pro-inflammatory mediators appears to be due, at least in part, to a decrease in the nuclear translocation of NFκB, a critical transcription factor for pro-inflammatory signaling. Additionally, these results are supported since microtubule dynamics may be involved in NFκB nuclear translocation. Here we expand the scope of our previous work by exploring the effects of a potentially more potent stereoisomer mix of the NT-07-16 analogue, NT-07-45 on other important pro-inflammatory signaling pathways in macrophages. Although the role of the microtubule network on inflammatory signaling has not been well-studied, our results demonstrate a decrease in the production of the antiviral and pro-inflammatory cytokine interferon-beta (IFNβ) after macrophages are exposed to NT-07-45. Also, results suggest that when macrophages are exposed to NT-07-45 prior to LPS activation the phosphorylation required for the activation of the transcription factor IRF3, which is responsible for initiating the production of IFNβ, is

altered. Altering the phosphorylation of IRF3 could affect the transcription factor entering the nucleus to induce IFNβ production. Our work has also found alterations in the phosphorylation of MAP-Kinases, which is required for their activation, in macrophages that have been exposed to NT-07-45. Therefore, these findings suggest that the decrease in the production of pro-inflammatory mediators observed in macrophages exposed to these polysubstituted pyrroles may be due to the inability of multiple transcription factors involved in the inflammatory response to efficiently translocate into the nucleus. While much is still to be learned about the anti-inflammatory mechanisms of these compounds it appears that the effects may go beyond their microtubule-depolymerizing activity.

Making New Connection between TOR, Autophagy, and Metabolism.

H. Tang[1], Y. Hu[1], C. Chen[1], B. Xia[1], A. M. John[2,3], L. Rabinow[1], N. Perrimon[1,4]; [1]Department of Genetics, Harvard Medical School, Boston, MA, [2]Department of Medicine, Harvard Medical School, Boston, MA, [3]Division of Signal Transduction, Beth Israel Deaconess Medical Center, Boston, Boston, MA, [4]Howard Hughes Medical Institute, Boston, MA.

Alternative mRNA processing, including alternative splicing (AS) and polyadenylation (APA), generates transcripts with different coding and UTR regions, a mechanism that regulates RNA stability and localization, protein-protein interactions, subcellular localization, and protein expression. Dysregulation of AS and APA have been linked to numerous cancers and diseases. Here, we show that the TOR signaling pathway regulates phosphorylation of the Cleavage and Polyadenylation (CPA) complex to induce AS and APA events in the Drosophila larval fat body during nutrient deprivation. CDK8 and DOA kinases are identified as links between TOR and the CPA complex. CDK8 and DOA physically interact with and directly phosphorylate CPSF6, a key component of the CPA complex, to regulate its cellular localization and RNA-binding ability. Significantly, depletion of CDK8, DOA, and the CPA complex compromises autophagy and promotes protein, energy, and lipid metabolism during starvation. These findings elucidate a regulatory mechanism linking between the TOR signaling pathway, RNA processing and metabolism.

P584/B598

A Tug-of-war Mechanism Drives the Allosteric Activation of Protein Kinase A.

L. Bai[1], J. England[1], S. S. Taylor[2], R. Maillard[1]; [1]Georgetown University, Washington, DC, [2]University of California, San Diego, La Jolla, CA.

Protein Kinase a (PKA) is an important regulatory enzyme in many signal transduction pathways. This study focuses on the mechanisms of allosteric communication between the PKA regulatory and catalytic subunits. The regulatory subunit establishes two sets of interactions with the catalytic subunit to form an inactive holoenzyme: 1) via the inhibitory sequence that docks into the active site of the catalytic subunit and is stabilized by ATP and two Mg^{2+} ions, and 2) via surface contacts between two cyclic nucleotide binding (CNB-A and CNB-B) domains. We use optical tweezers to investigate the crosstalk between the inhibitory sequence, ATP and Mg^{2+} with the surface contacts established between the CNB domains and the catalytic subunit. When ATP and Mg^{2+} are in saturation, we find that the CNB domains bound to the catalytic subunit are in equilibrium between two conformational states, a predominant conformation in which the CNB domains unfold independently of each other and at high force, and a minor conformation wherein the CNB domains unfold near-simultaneously or cooperatively and at low

force. In the absence of ATP or Mg^{2+}, a redistribution of the PKA ensemble occurs where the CNB domains only unfold cooperatively and at low force. Moreover, we investigate how the CNB-B domain controls the interaction of the CNB-A domain with the catalytic subunit. We show that the truncated CNB-A domain has a stronger interaction with the catalytic subunit compared to the CNB-A domain as part of the regulatory subunit. This result indicates that the CNB-B domain weakens the interaction between the CNB-A domain and the catalytic subunit. Altogether, this study portrays a PKA allosteric activation mechanism in which the CNB-A domain experiences a tug-of-war due to stabilizing effects conferred by the inhibitory sequence and ATP-Mg^{2+}, and destabilizing effects due to the presence of the CNB-B domain.

P585/B599

Dissecting Ligand-induced Domain Communication in Protein Kinase A.

A. K. Chau[1], Y. Hao[1], C. Canavan[1], S. S. Taylor[2], R. A. Maillard[1]; [1]Georgetown University, Washington, DC, [2]University of California, San Diego, La Jolla, CA.

cAMP-dependent protein kinase (PKA) is a biomedically important protein that regulates diverse cellular signaling pathways via allosteric regulation. PKA consists of the catalytic subunit that performs phosphorylation on protein substrates and the regulatory subunit that modulates the catalytic subunit's activity. The regulatory subunit has two cyclic nucleotide-binding (CNB-A/B) domains, where the binding of cAMP initiates the propagation of signals from one domain to the other and finally releases the catalytic subunit. How the protein's communication is modulated by ligand binding remains poorly understood. Here, we used isothermal titration calorimetry and optical tweezers to investigate how ligand binding affects one domain in the presence of the other. We find that CNB-A domain has a lower cAMP affinity than CNB-B domain. The binding affinity of both CNB domains increases when the other domain is present. This result highlights the influence of one CNB domain to the other is bidirectional and asymmetric. Additionally, we investigate W260 from CNB-B that serves as the capping residue on cAMP in CNB-A to probe the driving forces behind interdomain communication. The mutation W260A exhibits a decoupling effect between the CNB domains and destabilizes the conformation integrity in the bound state. This suggests W260 has important contributions to the CNB domains' ligand-binding cooperativity and structural stability. This study allows us to dissect how ligands induce domain communications in allosteric proteins. Moreover, this study enabled the identification and characterization of aberrant allosteric events associated with mutations observed in the disease state.

P586/B600

Chemical Genetic Approaches to Choanoflagellate Tyrosine Kinase Signaling.

F. U. N. Rutaganira, N. King; HHMI / Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA.

Although all organisms use signal transduction to respond to external stimuli, the rise of multicellularity necessitated the evolution of signaling pathways to coordinate actions of individual cells into a singular response. Phosphorylation, a molecular event mediated by kinases that transfer the terminal phosphate of ATP onto their substrates, is an essential signaling mechanism in animals. Tyrosine kinase (TK) signaling, characterized by reversible phosphorylation on tyrosine residues by TKs and phosphatases, has profound effects on cell growth, proliferation, and migration. Although kinase signaling is expanded in all multicellular lineages, TK signaling originated in holozoans. The identification of TK signaling in

choanoflagellates, the closest living relatives of animals, suggests a role for intracellular signaling that predated the evolution of obligate multicellularity in the animal stem lineage. Since many choanoflagellates form colonies, their TKs may also regulate choanoflagellate life history transitions. The choanoflagellate *Salpingoeca rosetta* differentiates into multiple solitary and colonial forms during its dynamic life history. Like other choanoflagellates, *S. rosetta* possesses an expanded TK signaling repertoire. Advances in TK inhibitor profiling and phosphoproteomics provide complementary approaches for identifying and elucidating how TK signaling influences choanoflagellate development. We are exploring the role of TK signaling in *S. rosetta* by conducting high-throughput phenotypic screens with structurally diverse kinase inhibitors and characterizing individual *S. rosetta* TKs with functional probes. In combination with recently developed reverse genetic tools to illuminate choanoflagellate cell biology, we aim to elucidate if tyrosine phosphosignaling pathways regulate *S. rosetta* life history. Because TK signaling is conserved between choanoflagellates and animals, insights into core signaling pathways in choanoflagellates can inform our understanding of modern animal development, physiology and disease.

P587/B601

A Context Dependent Requirement for Fig4 Catalytic Function in Yeast.

A. Muñoz-Rivera[1], H. Reeves[1], I. Khan[1], A. Habib[2], L. Weisman[2], **B. Strunk, 78212**[1,2]; [1]Trinity University, San an tonio, TX, [2]University of Michigan, an n Arbor, MI.

PI lipid phosphatases modulate signaling cascades through localized dephosphorylation of specific phosphoinositides (PI) on subcellular membranes. In addition, a number of these phosphatases regulate cellular processes through lipid phosphatase independent functions. Notably, Fig4, a PI 5-phosphatase proposed to dephosphorylate PI3,5P_2, has been shown to rescue neonatal defects in a Fig4 knock-out mouse suggesting that Fig4 plays important cellular roles independent of its catalytic activity. Fig4 activates its opposing kinase, Fab1, to facilitate dynamic elevation of PI3,5P_2 through association with the Fab1-Vac14-Fig4 complex; catalytically impaired Fig4 is proposed to effectively fulfill this key function. Nevertheless, mice expressing catalytically impaired Fig4 as the only copy of Fig4 display late on-set neurological abnormalities and have a reduced life span indicating that Fig4 catalytic activity is not dispensable for long-term homeostasis. Fig4 is not strictly required for growth in *Saccharomyces cerevisiae* (*S. cerevisiae*), but we show here that Fig4 confers a growth advantage to yeast cells grown on rapamycin. Strikingly, catalytically impaired Fig4 is toxic to yeast cells under these conditions, impairing growth even relative to total loss of Fig4. Toxicity of catalytically impaired Fig4 can be rescued by co-expression of wild-type Fig4 suggesting that toxicity under these conditions results from loss of catalytic function. These studies provide a new model for investigating physiological implications of loss of Fig4 catalytic activity.

PLK4 Phosphorylates DNA Damage Response Protein GADD45a.

N. J. Gosselin, G. Sivakumar, J. W. Hudson; University of Windsor, Windsor, ON, CANADA.

Polo-like kinase 4 (PLK4) is a serine/threonine kinase, which is best known for its role in triggering centrosome duplication. PLK4 proteins levels are thought to be maintained in a precise balance since reduced or elevated expression of PLK4 can cause numerical centrosome abnormalities resulting in aneuploidy. This can ultimately lead to malignancy. Our lab has shown that PLK4 interacts with and

phosphorylates growth arrest and DNA damage-inducible protein 45 alpha (GADD45a). GADD45a expression is induced by both p53 and BRCA1 and thus plays a role in the cells response to DNA damage in many forms such as UV and ionizing radiation (IR). GADD45a has been shown to bind to CDK1 and inhibit the interaction of the CDK1-cyclin B1 complex to induce G2/M cell cycle arrest. We have shown that heterozygous ($Plk4^{+/-}$) mouse embryonic fibroblasts (MEFs) have reduced levels of endogenous Gadd45a protein in comparison to wild-type MEFs. Our work suggests that reduced PLK4 levels correlate with GADD45a mislocalization. We have identified five putative phosphorylation sites on GADD45a targeted by PLK4 and mutated these sites to assess the effect of these phosphorylation events on GADD45a function. Flow cytometry was used to assess GADD45a activity, specifically the ability of the mutant GADD45a proteins to induce G2/M arrest. The localization of the GADD45a mutant proteins within the cell was determined as was their ability to interact with known GADD45a interacting partners such as PLK4 and NPM1. Our work in characterizing the interaction between PLK4 and GADD45a will help to better our understanding of the role that PLK4 plays in the DNA damage response and genomic fidelity.

Signaling from the PM/cytoplasm to the Nucleus

Crosstalk between the Hippo-YAP and Nuclear Factor-Kappa B-RELA Signaling.

B. Cinar[1,2], E. Said-Bandy[3], M. M. Almathkour[1], C. S. Moreno[4]; [1]Department of Biological Sciences, the Center for Cancer Research and Therapeutic Development, Clark Atlanta University, Atlanta, GA, [2]Winship Cancer Institute, Emory University, Atlanta, GA, [3]Department of Biology, Sotuh Carolina State University, Orangeburg, SC, [4]Department of Pathology & Laboratory Medicine, Biomedical Informatics, Winship Cancer Institute of Emory University, Emory University School of Medicine, Atlanta, GA.

The Hippo pathway controls cell-cell interaction and organ size by regulating cell proliferation and cell death. The transcriptional factor YAP1 (yes associated protein 1) and the TEAD transcription factors are critical nuclear mediators of the Hippo pathway signaling in mammals. The RELA protein is a subunit of the nuclear factor-kappa B (NF-kappa B) transcription factors. The objective of this study was to determine whether Hippo/YAP and NF-kappa B/RELA signaling interact in living cells. Here, we have demonstrated that native YAP1/TEAD and RELA proteins biochemically and functionally interact with each other in human LNCaP and C4-2 cell lines. Our co-immunoprecipitation (co-IP), western blot (WB), and proximity ligation assay (PLA) showed that endogenous YAP/TEAD and RELA physically interact inside the cells. Our immunofluorescence assays revealed that the expression of YAP1 and RELA proteins overlapped in the cytoplasm and the nucleus. Combined treatment of cells with RANKL (receptor activator of nuclear factor-kappa B ligand) and androgen hormone enhanced YAP1 and RELA colocalization and interaction, as demonstrated by co-IP/WB experiments. Moreover, our PLA confirmed that co-treatment of cells with androgen and SDF1a (stromal cell-derived factor 1 alpha) or RANKL increased YAP1 and RELA interaction both in the cytoplasm and nucleus compared with controls. Our promoter-reporter assays showed that the knockdown of YAP1 by siRNA significantly reduced the activity of an NF-Kappa B responsive promoter-reporter gene. We also showed that controlled expression of MST1/STK4, a potent inhibitor of YAP1, attenuated the NF-Kappa B promoter reporter activity. Additionally, our unbiased bioinformatics analysis of the YAP1/TEAD and RELA chromatin immunoprecipitation data led to the identification of several genes that are potentially co-regulated by

YAP/TEAD and NF- kappa B signaling. These findings suggest that interaction between the Hippo/YAP and NF-Kappa B/RELA plays a critical role in broad cellular biology.

P590/B604

The Potential Therapeutic Mechanisms of Laminin-111 Peptide for Dry Eye Disease.

Y. Tsao; Mackay Memorial Hospital, Taipei, TAIWAN.

Dry eye disease (DED) is a multifactorial disorder and often associated with chronic inflammation of the ocular surface. Integrins are heavily involved in various aspect of inflammation. In addition to modulating T cell homing by integrin αLβ2, emerging evidence suggests that integrin αvβ3 activation is critical for macrophage maintained in an inflammatory phenotype. Survival signaling induced by integrin α5β1 and αvβ3 has been discovered that is important for PMNs against extrinsic and intrinsic apoptotic signaling. Laminin-111 is known to contact and interact with integrins. Our recent animal studies shown that LDSP (a laminin-111 derived short peptide) therapeutically effective on DED and psoriasis, two inflammatory diseases. We found LDSP to be a α5β1 and αvβ3 antagonist. LDSP treatment has shown that can suppress the inflammatory phenotype (such as IL-1β) of macrophages by αvβ3-dependent manner. In addition, LDSP is able to induce PMNs apoptosis in an α5β1/αvβ3 dependent fashion. Interesting, our in vitro data reveal the corneal epithelial cells (CECs) also a LDSP target. LDSP can suppress IL-1βexpression and membrane lipid peroxidation induced by hyperosmotic stimuli. These suggest that integrin α5β1/αvβ3 may play a role for modulating inflammasome and autophagy. Our observation, for the first time, suggests that integrin α5β1/αvβ3 contributes to ocular inflammation and may a novel target for DED treatment.

P591/B605

Divergent Impacts of Nck1 and Nck2 Loss on Diabetic Podocytopathy.

C. R. Williamson, P. Lu, L. A. New, N. Jones; University of Guelph, Guelph, ON, CANADA.

Diabetic podocytopathy (DP) is a life-threatening kidney complication that involves damage to the podocyte slit diaphragm (SD), a molecular filter of large plasma proteins. It is currently unknown if the SD signaling adaptor proteins, Nck1 and Nck2, play a role in DP pathogenesis. Nck adaptors are critical to SD function, as podocyte-specific double knockout (KO) of both Nck paralogs impairs SD formation and maintenance, resulting in severe proteinuria. Interestingly, Nck1/2 single KO mice show no overt changes in podocytes, but it is possible these mice exhibit altered susceptibility to DP. Supporting this notion, glomerular mRNA levels acquired from the NephroSeq database reveal increased *Nck1*, but decreased *Nck2* in a subset of diabetic nephropathy patients. Thus, to characterize potentially unique roles of each paralog in DP pathogenesis, we examined the degree of SD injury in diabetic Nck1 and Nck2 KO mice. Male WT, Nck1KO, and Nck2KO mice were either administered streptozotocin for diabetes induction, or citrate buffer as a respective control. Proteinuria was assessed by albumin excretion rate using metabolic cage urine collections. We found the degree of albuminuria in Nck2KO mice to be greater than diabetic WT and Nck1KO mice. Glomerular cell density, volume, and sclerosis were estimated from periodic acid-Schiff-stained kidney sections. Glomerular cell loss was observed in diabetic Nck2KOs, but not in Nck1KO or WT mice. In contrast, both glomerulosclerosis and glomerular hypertrophy were increased in diabetic WT mice, but not in Nck KOs. Finally, glomeruli were isolated and lysed to measure levels of phosphorylated and total nephrin, an important SD protein and binding partner of Nck. No alterations in phosphorylated nephrin (p1176 and pY1193) were found, but total

nephrin protein levels were higher in diabetic Nck2KOs than in diabetic WTs and Nck1KOs. In summary, these findings provide evidence of separate roles for Nck1 and Nck2 in DP pathogenesis. In agreement with the NephroSeq dataset, we have shown that a loss of Nck2, but not Nck1, is associated with increased DP susceptibility. Future studies will address whether overexpression of Nck1 may instead promote DP. Altogether, Nck adaptors should be further investigated as potential genetic factors and therapeutic targets in DP and other kidney pathologies.

P592/B606

Beta-adrenergic Receptor Signaling Reduces Pro-inflammatory Signaling and Promotes the M2 Phenotype in the Raw264.7 Macrophage Cell Line.

F. Cabrera Paz, A. H. Pham, E. Gonye, K. Fischer-Stenger; University of Richmond, Richmond, VA.

Catecholamines alter macrophage function by binding to adrenergic receptors on the cell membrane. Stimulation through β_2-adrenergic receptors is known to down regulate the activity of classically activated M1 macrophages while stimulation through α-adrenergic receptors typically enhances their function. M1 macrophages initiate the pro-inflammatory response to eliminate infection while alternatively activated M2 macrophages down regulate the immune response and promote tissue repair. Our studies with the RAW264.7 murine macrophage cell line as a model for macrophage function support these findings. Macrophages were pre-treated with the selective β_2-adrenergic receptor agonist formoterol or the non-selective α-adrenergic receptor agonist clonidine prior to lipopolysaccharide (LPS) activation and analyzed for production of the proinflammatory cytokines tumor necrosis factor$_\alpha$ (TNF$_\alpha$) and interleukin-6 (IL-6) by ELISA. The results showed that formoterol decreases and clonidine increases macrophage cytokine production. The MAP-Kinase (MAPK) signaling pathway plays a role in the proinflammatory response, and our results obtained via western blotting showed that norepinephrine (NE) reduces the activation of extracellular signal-regulated kinases (ERK 1/2) and c-Jun N-terminal kinase (JNK) by decreasing the phosphorylation required to activate these MAPKs. Further studies using quantitative PCR (qPCR) showed that expression of inducible nitric oxide synthase (iNOS) mRNA was reduced while expression of arginase-1 (Arg-1) mRNA increased in macrophages pre-treated with NE prior to LPS activation. The iNOS enzyme catalyzes the production of nitric oxide, which has antimicrobial properties, and is a marker for M1 macrophages. The Arg-1 enzyme catalyzes the reaction of arginine to ornithine, a precursor to molecules participating in wound healing, and is indicative of M2 macrophages. Therefore, these findings suggest that stimulation of the adrenergic receptors by NE may also alter the phenotype of the macrophages. Additional studies using qPCR demonstrated that LPS activation decreased the expression of β_2-adrenergic receptor mRNA and increased the expression of α_{1A}- and α_2-adrenergic receptor mRNA in the macrophages, which may influence the inflammatory response in these cells. Taken together these findings suggest that exposure to NE may not only reduce the proinflammatory activity of macrophages but also induce development of the alternatively activated M2 phenotype in RAW264.7 macrophages.

P593/B607

Haptoglobin Inhibits Osteoclastogenesis through TLR4-IFN-beta Axis.

J. Kim[1], **Z. Lee**[2]; [1]Pediatric Dentistry, Seoul Natl University Sch Dentistry, Seoul, KOREA, REPUBLIC OF, [2]Cell and Developmental Biology, Seoul Natl University Sch Dentistry, Seoul, KOREA, REPUBLIC OF.

Haptoglobin (Hp), a type of acute-phase protein, is known to have a systemic anti-inflammatory function and to modulate inflammation by directly affecting immune cells, such as T cells, dendritic cells, and macrophages. However, the effects of Hp on osteoclast differentiation are not well studied, even though osteoclast precursor cells belong to a macrophage-monocyte lineage. In this study, we found that the bone volume was reduced, and the number of osteoclasts was increased in Hp-deficient mice compared with wild type mice. Moreover, our in vitro studies showed that Hp inhibits osteoclastogenesis by reducing the protein level of c-Fos at the early phase of osteoclast differentiation. We revealed that Hp-induced suppression of c-Fos was mediated by increased IFN-b levels. Furthermore, Hp increased IFN-β level via a TLR4-dependent mechanism in bone marrow-derived macrophages. These results suggest that Hp may play a physiological role in suppressing bone loss through the Hp-TLR4-IFN-β axis in addition to inflammatory response alleviation in inflammatory-related diseases.

P594/B608

Osthole Prevents Advanced Glycation End Products-induced Renal Tubular Hypertrophy by Suppressing Translationally Controlled Tumor Protein Expression.

J. Huang, Y. Liu, P. Lin; Chung Hwa University Med Technol, Tainan, TAIWAN.

Diabetic nephropathy (DN) is one of the most common diabetic complications, and advanced glycation end products (AGE) and their receptors play vital roles in pathogenesis of DN. Osthole has been widely reported to have anti-diabetic activity. Translationally controlled tumor protein (TCTP) has emerged as an important regulator of many biological processes and expressed ubiquitously in mammaliantissues. However, potential roles and molecular events for osthole and TCTP in DN remain unclear. The objective of this study was to clarify the role of TCTP in AGE-induced renal tubular hypertrophy and investigate the effect of osthole on TCTP expression. We found that raising the ambient AGE concentration causes a dose-dependent increase in TCTP synthesis in renal tubular cells. Osthole-treated and TCTP-specific siRNA-transfected cells showed significant decrease of AGE-induced TCTP protein expression. Osthole and TCTP siRNA treatments significantly attenuated AGE-induced nuclear factor-kappaB (NF-κB)/p65 activation. The decrease of inhibitor of NF-κB α (IκBα) and the increase of phosphorylated IκBα were reversed by osthole and TCTP siRNA. Moreover, the extracellular signal-regulated protein kinase (ERK) and p38 mitogen-activated protein kinase (p38 MAPK) activation were attenuated by osthole and TCTP siRNA in AGE-cultured cells. The abilities of osthole and TCTP knockdown to suppress AGE-induced cellular hypertrophy were verified by the observation that osthole and TCTP siRNA inhibited protein synthesis of RAGE, fibronectin, $p27^{Kip1}$ and α-SMA, total protein content, and cell size. Consequently, we found that osthole attenuated AGE-induced renal tubular hypertrophy via reduction of TCTP expression and suppression of the NF-κB/p65 and ERK/p38 MAPK activation. These results also showed that TCTP might be used as a unique molecular target for the treatment of DN.

P595/B609

The Transcriptional Cofactor Vgll3 Is a Novel Inducer of Epithelial-to-mesenchymal Transition.

N. Yamaguchi, H. Takano, N. Yamaguchi; Chiba University, Chiba, JAPAN.

Epithelial-to-mesenchymal transition (EMT) is a process that converts adherent epithelial cells to motile mesenchymal cells during embryonic development and tumor progression. Transforming growth factor-β (TGF-β) is a multifunctional cytokine that regulates various cellular processes, including EMT. Because TGF-β-induced EMT is involved in tumor progression, understanding of the molecular mechanisms underlying TGF-β-induced EMT is important for understanding the nature of tumors. To investigate the molecular mechanisms of TGF-β-induced EMT, we analyzed three gene expression profiles in TGF-β-stimulated cells and identified genes whose expression levels were commonly up-regulated by TGF-β stimulation. We selected several genes whose involvement in EMT was unclear and then established A549 stable lines expressing each gene. Stable expression of one of these genes, encoding VGLL3 (Vestigial-like family member 3), was found to induce morphological changes and repress expression of the epithelial marker E-cadherin. Wound-healing assays showed that stable expression of VGLL3 increased cellular mobility. These results suggested that stable expression of VGLL3 induces EMT progression in A549 cells. VGLL3 is thought to be a transcriptional co-factor for the transcription factor family TEAD (TEA-domain transcription factor). Immunoprecipitation assays showed that VGLL3 binds to TEAD1 and TEAD4, and knockdown of these TEADs repressed EMT phenotypes of VGLL3-expressing cells, suggesting that VGLL3 promotes EMT through activation of TEADs. We next analyzed the role of endogenous VGLL3 in EMT. siRNA-mediated knockdown of VGLL3 was shown to repress EMT progression upon TGF-β stimulation. High level expression of VGLL3 was observed in mesenchymal-like tumor cell lines, and knockdown of VGLL3 repressed mesenchymal-like phenotypes of these cells. These results indicated that VGLL3 is involved in EMT progression in tumor cells as well as in TGF-β-stimulated cells. Currently, analyses of molecular mechanisms of EMT progression by VGLL3 are underway.

P596/B610

PRL-1 Overexpressing Placenta-derived Mesenchymal Stem Cells Inhibit Adipogenesis in Orbital Fibroblast with Graves' Ophthalmopathy.

J. Kim, D. Kim, S. Park, J. Cho, S. Jun, J. Jun, J. Seok, S. Bae, G. Kim; CHA university, Seongnam, KOREA, REPUBLIC OF.

Graves' ophthalmopathy (GO) is an autoimmune inflammatory disease of the orbit and is characterized by proptosis impairment of eye motility, lid retraction, de novo adipogenesis. The present medical radiotherapy results in developing malignancies. Recently, Placenta-derived mesenchymal stem cells (PD-MSCs) have unique immunomodulatory properties for tissue repair and regenerative medicine. However, PD-MSCs have a restriction on the limited self-renewal ability. Phosphatase of regenerating liver-1 (PRL-1) regulates self-renewal ability of stem cells and promotes proliferation as well as prenylated protein tyrosine phosphatases (PTPs) for inhibiting adipogenesis. Hence, the major objective is to generate and characterize PRL-1 overexpressing PD-MSCs (PRL-1(+)) using nonviral AMAXA gene delivery system and to investigate mechanisms alleviating adipogenesis by PRL-1(+) PD-MSCs in orbital fibroblast (OF) derived from GO patients. PRL-1(+) PD-MSCs were successfully generated using nonviral AMAXA gene delivery system, and analyzed their characterizations including stemness markers, differentiation, and teratoma formation. OF with GO patients induced adipogenic differentiation, and cocultured with naïve and PRL-1(+) PD-MSCs. The mRNA and protein levels of adipocyte-specific

markers, insulin-like growth factor (IGF)-binding proteins (IGFBPs), and pPI3K/AKT/mTOR pathways were confirmed by quantitative real time polymerase chain reaction (qRT-PCR) and western blotting. The characterizations of PRL-1(+) PD-MSCs were similar to naïve. OF with GO patients stimulated adipocyte differentiation was significantly decreased lipid accumulation by cocultivation with PRL-1(+) PD-MSCs compared with naïve. The mRNA and protein expression of adipogenic markers were declined in PRL-1(+) PD-MSCs (*p<0.05). The expression of pPI3K/AKT/mTOR protein in OF with GO patients was downregulated by cocultivation with PRL-1(+) PD-MSCs secreted IGFBPs. Interestingly, IGFBP2, 4, and 7 expressions through integrin alpha 4 (ITGA4) and beta 7 (ITGB7) in PRL-1+ PD-MSCs were higher than naïve and upregulated pFAK downstream factor (*p<0.05). These results indicate that secreted IGFBPs by PRL-1+ PD-MSCs inhibit adipogenesis of OF with GO patients through upregulated FAK and downregulated IGF. Taken together, these findings provide novel therapeutic approach using next-generation MSC-based cell therapy for autoimmune diseases. **Funding sources:** This research was supported by grants of the Korea Health Technology R&D Project through the Korea Health Industry Development Institute (KHIDI) (HI17C1050), the National Research Foundation of Korea Grant funded by the Korean Government (F19SN22T1305), Republic of Korea.

Initial Characterization of Hc9orf78: Regulation by Serum and Evidence of Centromere/kinetochore Localization.

R. Koranne, L. Lenczewski, D. Rathnayake, W. Taylor; University of Toledo, Toledo, OH.

C9ORF78 is a poorly characterized protein found in diverse eukaryotes. Previous work indicated overexpression of hC9ORF78 (aka HCA59) in hepatocellular carcinoma indicating a possible involvement in growth regulatory pathways. Recently, Wang J. et al showed that Tls1, a putative fission yeast homolog of hC9ORF78, was required for telomeric heterochromatin assembly by regulating splicing of shelterin complex proteins Rap1 and Poz1 (Wang, J. et al., 2014). Consistent with this, interactome studies indicate that hC9ORF78 associates with the spliceosome (Ilagan J.O. et al., 2013). In contrast, we observed an increase in expression of TERF2IP (fission yeast homolog of Rap1) after knockdown of C9ORF78 in HeLa cells. In addition, we observed an increase in POT1 levels in contrast to no change in similar experiments in fission yeast. We hypothesize that hC9ORF78 regulates splicing differently in humans and yeast. In studies of GFP-tagged hC9ORF78 we observed a dramatic reduction in protein abundance in cells grown to confluence and/or deprived of serum growth factors. Serum stimulation induced synchronous re-expression of the protein in HeLa cells. This effect was observed with CMV-driven N-terminally GFP tagged protein, C-terminal GFP tagging of the endogenous locus, and by western blotting for the endogenous untagged protein. These data suggest C9ORF78 protein is destabilized in growth factor deprived cells. We also observe a dramatic upregulation of the shelterin component TERF2IP(Rap1 in Fission yeast) and POT1 in serum-deprived cells and are investigating to what extent this is due to hC9ORF78 regulation. Finally, we have started to characterize the subcellular localization of hC9ORF78 using GFP as well as polyclonal antibodies to the endogenous protein. hC9ORF78 localizes to nuclei in interphase, but does not appear to concentrate at speckles. Surprisingly, a subpopulation of hC9ORF78 co-localizes with ACA in mitotic cells suggesting that this protein may associate with kinetochores or centromeres. Given its association with the spliceosome, we are intrigued by the possibility that hC9ORF78 is part of splicing factors recruited at the kinetochore for processing of ncRNA during mitosis. In either case, our preliminary characterization suggests that hC9ORF78 may have multiple functions in telomere regulation, cell growth control and possible mitosis.

The Epithelial Innate Immune System Quantifies Microbe Associated Molecular Patterns through an Epigenetic Digital Signaling Mechanism.

C. D. McKenney, H. R. Clark, S. Regot; Johns Hopkins University Sch Med, Baltimore, MD.

Epithelial cells perform a delicate role in the innate immune system: they must protect against biological threats without damaging the host or its commensal microbiota. Accordingly, Microbe Associated Molecular Patterns (MAMPs) must be accurately identified and quantified to execute appropriate responses. Here we use live cell imaging of innate immune signaling in mammary epithelial monolayers to study the mechanisms by which tissues and individual cells enforce appropriate quantitative responses to MAMPs and inflammatory cytokines. We conducted a comprehensive screen measuring single-cell nuclear translocation and transcriptional activation of NF-κB upon stimulation of Toll Like Receptors (TLRs) 1/2, 3, and 5, as well as IL-1R and TNFR. Our results show that epithelial cells respond to bacterial MAMPs as a population by differentially activating fractions of cells in an all-or-nothing, or digital manner. This digital signaling is maintained through epigenetic mechanisms that regulate receptor expression levels in fractions of cells. This regulation allows epithelial cells to sub-specialize within the context of a monolayer to sense identity and strength of bacterial inputs.

Quantitatively Defining Wnt Signaling in Colon Cells.

M. Cantoria[1], E. Alizadeh[1], E. Lee[2], C. A. Thorne[1]; [1]University of Arizona, Tucson, AZ, [2]Vanderbilt University, Nashville, TN.

WNT signaling is involved in organism development, maintenance of proliferative stem cells, and development of disease. We seek to uncover how individual cells mount a robust response to activation of the WNT pathway. Using *Xenopus laevis* oocytes, previous work in our lab shows positive feedback between two components of the destruction complex - glycogen synthase kinase 3 (GSK3) and the scaffolding protein Axin. GSK3 stabilizes Axin by preventing its degradation over time. Axin binds GSK3, targeting GSK3 for dephosphorylation by protein phosphatase 2A (PP2A), leading to its activation. Mathematical modelling using ordinary differential equations predicts a bistable response to WNT activation. We experimentally validate the model in non-malignant human colonic epithelial cells (HCECs). We activate the WNT pathway using the GSK3 inhibitor CHIR99021 (GSK3i), using nuclear localization of the WNT effector protein β-catenin as readout, measured by high throughput microscopy. We measured a feature of a bistable system called hysteresis. HCECs respond to GSK3i in a hysteretic manner, showing about 2-fold decrease in EC_{50} of cells that were pre-activated ($EC_{50} \pm$ SEM = 1.7 μM $\pm$ 0.4) with a high dose of GSK3i (10 μM) compared to naïve group (DMSO control; $EC_{50} \pm$ SEM = 3.3 μM $\pm$ 0.9). Our data show that positive feedback between GSK3 and Axin lead to a hysteretic and therefore, bistable response to activation of the WNT pathway through GSK3 inhibition. Future studies will determine if HCECs that possess tumor suppressor and oncogenic mutations lose their bistable response to GSK3i.

Spi-C Enhances Osteoclast Differentiation by RANKL Stimulation.

E. GO, S. LEE, D. LEE, D. KIM, **N. LEE**; Soonchunhyang University, ASAN, KOREA, REPUBLIC OF.

SPI-C is a SPI-group ETS transcription factor expressed temporarily during B-cell development and in macrophages. However, it has so far been little studied on the involvement of SPI-C with osteoclastogenesis. Osteoclasts are multinucleated cells derived from hematopoietic progenitors of the bone marrow-derived monocyte/macrophages. We present here that SPI-C is a novel positive regulator of RANKL-induced osteoclast differentiation. Spi-C is up-regulated during osteoclast differentiation, and the knockdown of Spi-C effectively decreased the RANKL-induced osteoclast marker gene expression as well as resulted in a remarkable decrease of the number of TRAP-positive multinucleated cells. Spi-C overexpression significantly enhanced osteoclast formation by RANKL and the knockdown of Spi-C blocked the activation of MAP kinases and IκBα by RANKL. RANKL-mediated Spi-C expression was JNK-dependent, and the translocation into nucleus of Spi-C was suppressed by the inhibitors of p38 MAP kinase and PI3K. BMMs pretreated with these inhibitors failed to differentiate into osteoclasts. Collectively, these results suggest that Spi-C plays a critical role in RANKL-induced osteoclast differentiation. *This work was supported by NRF-2016R1D1A1B01012205.

Lgr-independent Potentiation of Wnt Signaling by R-spondins: Mechanism and Functions in Development.

A. M. Lebensohn[1], R. Rohatgi[2]; [1]National Cancer Institute, National Institutes of Health, Bethesda, MD, [2]Stanford University, Stanford, CA.

The WNT signaling pathway encodes positional information in animals, orchestrates patterning and morphogenesis during embryonic development, and promotes tissue renewal and regeneration in adults. Dysregulation of WNT signaling has been implicated in many diseases, including developmental malformations, skeletal and dental abnormalities, cardiovascular and neurodegenerative disorders, diabetes, and many types of cancer. Members of the R-spondin family of secreted growth factors have emerged as key regulators of WNT signaling strength. The R-spondin system is a vertebrate adaptation that may be related to the appearance of sophisticated stem cell compartments, which require exquisite control of WNT signaling. The four members of the family (R-spondin 1-4) can strongly potentiate responses to WNT ligands during development and in stem cells, but the mechanisms by which they transduce signals are not fully understood and the reasons why they produce different physiological effects are largely unknown. Unexpectedly, we discovered that R-spondins 2 and 3 can uniquely potentiate WNT signaling in cells lacking LGRs 4, 5 and 6, the principal R-spondin receptors. We determined the protein domains on R-spondins necessary and sufficient for this new mode of signaling, and showed that it is mediated by an alternative interaction with cell-surface heparan sulfate proteoglycans. This finding is transformative because LGRs 4-6 were thought to be required to transduce all R-spondin signals and hence determine their site of action. Indeed, these LGRs are highly expressed in many stem cell compartments whose maintenance depends on potentiation of WNT signaling by R-spondins. Instead our work shows that there are two modes of signaling by R-spondins, an LGR-dependent and an LGR-independent mode, and that different R-spondins may use distinct molecular mechanisms to transduce signals in various biological contexts. Supporting our findings, recent work from another group demonstrated that during limb development, R-spondin 2 signals through an LGR-

independent mechanism. I will present the results demonstrating our conclusions and discuss their implications in development and tissue homeostasis.

BMP Receptor Agonists: a Rare Find in BMP Receptor Pharmacology.

R. Rathod, L. Barasa, S. Yoganathan, J. Perron; St.John's University, NewYork, NY.

Bone Morphogenetic Proteins (BMPs) are set of powerful morphogens which play critical roles in development of the nervous system, regulating activities such as differentiation and migration of progenitor cells, as well as formation of neural circuits. BMPs are known to play fundamental roles in many organ systems like skeletal, cardiovascular, pulmonary and gastrointestinal. They are also required for maintaining homeostasis in adult tissue like facture repair, vascular remodelling and maintaining joint integrity. Because of their ubiquitous presence in different organ systems, perturbation in BMP signaling can lead to marked developmental defects or severe pathologies later in life. BMP signaling is highly regulated by intracellular, extracellular and membrane modulators. Currently, the small molecules known to regulate BMP signaling are largely antagonists. The few compounds that have been identified as positive regulators of BMP activity, primarily act as enhancers or sensitizers. To date, no full agonist of BMP signaling has been identified. In this study, we have analysed a novel series of compounds, which share a core structure with an identified sensitizer of BMP activity (PD407824). Our results suggest that select compounds from this series of small molecules demonstrate BMP receptor agonist activity by stimulating both Smad- and PI3K-dependent signaling pathways in C2C12 cells, as well as in human pulmonary endothelial cells. The active compounds also appear to act as enhancers of BMP activity when used in combination with subthreshold concentrations of BMPs. Morevoer, we have determined that stimulation of Smad phosphorylation by our active compounds is dependent on signaling through type I BMP receptor subunits by using the type I BMP receptor inhibitor, Dorsomorphin. We are now exploring the functional similarities of these compounds to the transcriptional, inductive and chemotropic actions of BMPs by 1) determining whether these compounds upregulate target genes similar to those stimulated by BMPs, as well as, induce the differentiation of C2C12 myoblasts into osteoblasts using RT-PCR and ALP assays and 2) assessing whether these compounds promote chemotropic activity using chemotaxis and wound-healing assays. Identification of potent BMP receptor agonists would be valuable for controlling stem cell differentiation, as potential therapeutics for the treatment of BMP-related disorders, such as pulmonary arterial hypertension, or for promoting wound healing.

P603/B617

Investigating the Effects of Resveratrol on Combating Inflammation Induced by Exposure to Inhaled Pollutants.

P. Kwarteng, S. Jones; University of Richmond, Richmond, VA.

The goal of this research was to evaluate the anti-inflammatory effects of resveratrol on macrophage inflammation induced by woodsmoke and acrolein exposure. Resveratrol is a compound normally found in the skin of red grapes that has anti-inflammatory, antioxidant, metabolic, and cardioprotective qualities. Woodsmoke is generated from the burning of wood, whereas acrolein is an aldehyde derived from smoke in house and forest fires, cigarette smoke, cooking oil, etc. Although there is limited published research on resveratrol as an option to limit the effects of inflammation, existing research

shows that it works by regulating, activating, or deactivating various regulatory pathways and cytokine production (via the NF-kB signaling pathway). We exposed a murine RAW 264.7 macrophage cell line to lipopolysaccharide (LPS) and zymosan (two compounds that work to stimulate the innate immune response) and woodsmoke. After toxicant exposure, we used techniques including Lactate Dehydrogenase (LDH) assay, Polymerase Chain Reaction (PCR)/gel electrophoresis, and Sandwich Enzyme-Linked Immunosorbent Assay (ELISA) to assess the ability of resveratrol to inhibit inflammation. These assays tested for cellular cytotoxicity, inflammatory gene expression, protein production, etc. Thus far, our data suggest that macrophages exhibit increased levels of pro-inflammatory gene expression when exposed to LPS, zymosan, and woodsmoke alone. We also saw that when increasing concentrations of resveratrol were added, resveratrol had some inhibitory effects on woodsmoke (regarding gene expression and protein production), but not observed effect on LPS and zymosan. The downstream signaling pathways are known for LPS and zymosan, but the pathways leading to woodsmoke-induced inflammation are currently unknown. These data suggest that the signaling pathways used for LPS and zymosan are clearly different from that of woodsmoke. In the future, we wish to continue to gather data on woodsmoke signaling pathways, acrolein exposure, and other assays to look at levels of phagocytosis and cell surface protein changes.

P604/B618

Pact Facilitates Activation of the Notch Signaling Pathway by Strengthening the Association between Cbf1 and Notch Intracellular Domain.

S. Lee, S. Byun, M. Kwon, H. Noh, **K. Yoon**; Sungkyunkwan Univ., Suwon, KOREA, REPUBLIC OF.

The protein activator of protein kinase R (PKR) (PACT) is known to play important roles in PKR regulation and microRNA biogenesis. Based on the observation that PACT is specifically expressed in the ventricular zone (VZ) at the mid-neurogenic period, we examine the role of PACT in this embryonic neural stem cell niche. Here, we provide the first evidence that PACT increases neurosphere formation, as well as expression of Notch target genes and the neural stem cell marker Sox2 in primary neural stem cells in *vitro*. Consistently, introduction of PACT into the mouse embryonic brain in *utero* increased the fraction of cells localizing to the VZ. We also show that the PACT-enhanced stemness of neural stem cells is PKR-independent. At the molecular level, PACT was revealed to physically interact with C promoter binding factor 1 (CBF1) and dramatically strengthen the association between CBF1 and Notch intracellular domain (NICD), which indicates stabilization of the Notch transcriptional coactivation complex responsible for Notch target gene expression. Taken together, our study indicates that PACT is a novel transcriptional coactivator of the Notch pathway playing a pivotal role during mammalian brain development.

P605/B619

P63 Control of Desmosomal Gene Regulation and Adhesion Is Compromised with Mtorc1 Loss of Function.

S. Murali[1], K. Asrani[1], Z. Khan[2], T. Lotan[1]; [1]Johns Hopkins University Sch Med, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD.

The transcription factor p63 (isoforms TAp63 and DNp63) is essential for the formation of epidermis and other stratifying epithelia as demonstrated by the severe skin abnormality of p63-deficient mice and by the development of certain types of ectodermal dysplasia in humans as a result of p63 mutations.

However, the molecular determinants of p63 regulation and its specific role in the transcriptional program regulating epidermal fate remain poorly characterized. Patients with AEC (Ankyloblepharon, ectodermal defects, cleft lip/palate) syndrome caused by mutations in p63 exhibit severe skin fragility and blistering due to reduced desmosomal gene expression. Studies from our lab previously showed that mTORC1 is an essential driver of epidermal morphogenesis, stratification and desmosomal gene regulation, with epidermal Rheb and Rptor cKO mice exhibiting a similar phenotype as seen in AEC patients and p63-null mice. We investigated the role of p63 in mediating this phenotype, downstream of mTORC1. Mice with mTORC1 loss of function have reduced basal nuclear p63 expression in the epidermis. *Rptor* floxed keratinocytes treated with cre recombinase (*Rptor* cre) showed decreased whole cell and nuclear expression of TAp63 and DNp63 isoforms by western blotting. Over-expression of both p63 isoforms in *Rptor* cre keratinocytes rescued expression of desmosomal proteins and cellular adhesion, as seen by western blots and dispase assays respectively. In mice with mTORC1 loss of function, we previously found that Rho kinase (ROCK) signaling was constitutively activated, resulting in increased cytoskeletal tension and impaired cell-cell adhesion, and ROCK inhibition rescued desmosomal levels and adhesion. mTORC1 loss of function also resulted in marked feedback upregulation of upstream TGF-β signaling, triggering ROCK activity and its downstream effects on desmosomal gene expression. However, the transcription factors mediating these effects remain uncharacterized. A recent study reported that ROCK is a negative regulator of p63 and we found whole cell and nuclear levels of p63 to be rescued by ROCK inhibition in *Rptor* cre keratinocytes by western blotting. Whole cell and nuclear levels of p63 was also rescued by TGF-β inhibition in *Rptor* cre keratinocytes by western blotting. Increased nuclear localization of p63 was also observed in *Rptor* cre keratinocytes with TGF- β signaling inhibition. These data suggest that p63 expression and/or activity may be regulated by TGF-β signaling upstream of mTORC1 and ROCK signaling downstream of mTORC1.

P606/B620

Endosomal Regulation of DAF-16 FOXO and Insulin/IGF Signaling.

I. Meras, L. Chotard, T. Liontis, Z. Ratemi, B. Wiles, J. Van Raamsdonk, **C. Rocheleau**; McGill University, Montreal, QC, CANADA.

The insulin/IGF signaling pathway negatively regulates a conserved family of FOXO transcription factors that play a major role in aging, metabolism and stress responses. Phosphorylation of FOXO by AKT kinases leads to 14-3-3 binding and sequestration of FOXO in the cytoplasm. Subsequent ubiquitination targets FOXO for degradation. However, it is not known if extranuclear FOXO is compartmentalized or just diffuse in the cytoplasm. *C. elegans* has a single FOXO, DAF-16. We investigated DAF-16::GFP subcellular localization by epifluorescence and confocal microscopy. We found that DAF-16 localizes to vesicles in the intestinal cells. The number of vesicles per cell is variable, ranging from zero to much greater than 50. This localization is partly dependent on insulin/IGF signaling and the RLE-1 E3 ubiquitin ligase. We find that DAF-16-positive vesicles correspond to a subset of RAB-5 and RAB-7 positive endosomes. In *tbc-2* mutant worms, which have increased RAB-5 activity, endomembrane localization of DAF-16 is greatly expanded at the expense of nuclear localization. We found that TBC-2 is required for the increased fat storage and extended lifespan of *daf-2 IGF receptor* mutant animals suggesting that endomembrane localization serves to sequester and or inhibit DAF-16. We are testing if TBC-2 regulates the expression of DAF-16 target genes using transcriptional reporters and qRT-PCR. These findings identify endosomes as a potential site of DAF-16 regulation and suggest that FOXO proteins could similarly be regulated on endosomes in human cells.

P607/B621

Translational Regulation of Cav2.2 by the Sigma-1 Receptor at the Dorsal Root Ganglia during Neuropathic Pain.

S. Wang, N. Goguadze, Y. Kimura, T. Su, **H. Wu**; NIDA/NIH, Baltimore, MD.

Primary sensory neurons at the dorsal root ganglia (DRGs) signal for neuropathic pain, when pathophysiologic damages elicita hyperexcitability in DRG neurons. We have previously demonstrated that the blockade of the sigma-1 receptor (Sig-1R) can reverse the diminished inward Ca^{2+} current (I_{ca}) which is a known feature of nerve injury in primary sensory neurons. One of the potential Ca^{2+} channels responsible for the I_{ca} is Cav2.2. In the present study we examined the potential transcriptional and translational controls of Cav2.2 by the Sig-1R in DRG during neuropathic pain induced by spared nerve injury (SNI) and explored the underpinning molecular mechanism thereof. To this end, the Cav2.2 protein expression level, and the mRNA level were compared in DRGs obtained from skin shame (SS) control and SNI rats. Immunoblotting showed a decrease of the Cav2.2 protein expression but not its mRNA level, indicating either a protein degradation or a translational regulation. In the protein degradation test, we found that ubiquitination of Cav2.2 did not differ in wild-type or Sig-1R knockout (KO) HEK cells under the condition when proteasome is inactivated by using NG132. This suggested that the decrease of Cav2.2 protein is related to translational processes. Using the RNA-immunoprecipitation assay, we found that the eukaryotic initiation factor eIF4E can increase its binding to Cav2.2 mRNA in Sig-1R KO HEK cells when compared to wild-type HEK cells. On the other hand, it has been demonstrated that 4E-BP1 can interact with eIF4E and attenuate the eIF4E binding to the mRNA 5'-cap to decrese the initiation of the translation of the mRNA. We reasoned that the Sig-1R may regulate 4E-BP1.We found that 4E-BP1 protein and mRNA were both decreased in Sig-1R KO HEK cells and interestingly were both increased in SNI DRGs, suggesting that the Sig-1R upregulates the transcription of 4E-BP1. Further, although 4E-BP1 did not directly interact with Sig-1R in HEK cells, 4E-BP1 increased its interaction with eIF4E in SNI DRGs, blunting the initiation of mRNA translation. Taken together, our results suggest that a decreased of Cav2.2 expression after nerve injury is due to the inactivation of eIF4E which in turn is governed by the level of the 4E-BP1 seemingly controlled by the Sig-1R. However, the Sig-1R regulation on the 4E-BP1 expression needs further examination.

Dynamics of Focal Adhesions and Invadosomes

P608/B623

Analyzing the focal adhesion mechanics using novel Src and p130Cas-based FRET Biosensors.

L. Koudelkova[1], C. Pataki[1], O. Tolde[1], V. Kolomaznikova[1], V. Pavlik[1], K. An derson[2], J. Brabek[1], **D. Rosel**[1]; [1]Charles University, Faculty of Science, Praha, CZECH REPUBLIC, [2]The Francis Crick Institute, London, UNITED KINGDOM.

Focal adhesions (FAs) are dynamic adhesion structures mediating bidirectional mechanical and signaling link between ECM and intracellular actin cytoskeleton. Many FA-constituting proteins have the ability to function as mechanosensors; proteins that respond to mechanical stress by changing their conformation and transmit the mechanical stimuli to cellular response. P130Cas and more recently also Src tyrosine kinase were proposed to function as such mechanosensors in FAs. To analyze the role of Src and its main substrate in FAs p130Cas we have developed FRET-based biosensors allowing us to monitor

conformational changes and activity of Src, p130Cas phosphorylation and tension induced stretch of substrate domain of p130Cas in live cells. Based on the results obtained with the Src-FRET biosensor we proposed a new model for the role of Src and Src-dependent phosphorylation in focal adhesions. According to the model, Src is rapidly activated during focal adhesions assembly and Src-dependent tyrosine phosphorylation of focal adhesion proteins drives the assembly phase of focal adhesions. It remains stable during maturation of focal adhesions due to counteracting activity of tyrosine phosphatases. Hyperphosphorylation of the Src targets in focal adhesions, potentially due to decreased activity tyrosine phosphatases, induces focal adhesions' disassembly which is followed by gradual Src inactivation. P609/B624

The Role of APC-mediated Actin Assembly in Microtubule Capture and Focal Adhesion Turnover.

M. A. Juanes[1], D. Isnardon[2], A. Badache[2], S. Brasselet[3], M. Mavrakis[3], B. L. Goode[1]; [1]Brandeis University, Waltham, MA, [2]Centre de Recherche en Cancérologie de Marseille, Inserm, Institut Paoli-Calmettes, Aix Marseille Université, Marseille, FRANCE, [3]Aix Marseille Université, CNRS, Centrale Marseille, Institut Fresnel, Marseille, FRANCE.

Focal adhesions (FA) are highly dynamic structures that assemble at the front of the cell and disassemble at the rear, allowing cells to move directionally. Focal adhesion (FA) turnover depends on microtubules and actin. Microtubule ends are captured at FAs, where they induce rapid FA disassembly. However, actin's roles are less clear. Here, we use polarization-resolved microscopy, FRAP, super-resolution microscopy, live-cell imaging, and a mutant of Adenomatous polyposis coli that is incapable of nucleating actin (APC-m4) and impairs directional cell migration (Juanes et al., 2017; *J. Cell Biology*) to investigate the role of actin assembly in FA turnover. We show that APC-mediated actin assembly is critical for maintaining normal F-actin levels, organization, and dynamics at FAs, along with proper organization of FA components, including Src and FAK Kinases, and Paxillin. Live imaging in wild type cells shows that microtubules are captured repeatedly at FAs as they mature, but once a FA reaches peak maturity, the next microtubule capture event leads to delivery of an autophagosome, triggering FA disassembly. In APC-m4 cells, microtubule capture frequency and duration are altered, and there are long delays between autophagosome delivery and FA disassembly. Thus, APC-mediated actin assembly is required for normal feedback between microtubules and FAs, and maintaining FAs in a state 'primed' for microtubule-induced turnover. In addition, we found that APC-m4 expression or silencing of the formin Dia1 each caused a ~30% reduction in total F-actin levels in cells; however, Dia1 silencing led to only modest defects in FA turnover. Thus, APC-m4 effects on FA turnover do not arise from a general loss of actin assembly in cells, but rather from a specific disruption of APC-mediated actin nucleation at FAs. In summary, this work demonstrates that APC is a *bona fide* actin nucleator in *vivo*, and that this activity of APC is crucial for regulating FA turnover underlying directed cell migration. Importantly, our results do not rule out the possibility of other actin assembly-promoting factors contributing to FA turnover, or APC coordinating actin and microtubule dynamics in other cellular locations besides FAs.

P610/B625

Limd1 Phase Separation Contributes to Cellular Mechanics and Durotaxis by Regulating Focal Adhesion Maturation Under Force.

Y. Wang, C. Zhang, S. Shao, Y. Sun, L. Liang, C. Wu; Peking University, Beijing, CHINA.

Cells sense and respond to extra-cellular mechanical environment through cell-matrix adhesions. Interestingly, the maturation of focal adhesions (FAs) is reciprocally force-dependent. How this mechano-chemical coordination is achieved at cellular and molecular levels remains enigmatic. Meanwhile, how biomechanical cues in the extracellular environment dictate the status of cell motility is yet to be determined. LIMD1, a member of the LIM domain proteins, localizes to the FAs and has been reported to negatively regulate the Hippo-YAP signaling pathway in response to tension. Here we identify the force sensitive recruitment of LIMD1 to the FAs. We discover that LIMD1 maintains FA dynamics and composition, and regulates cell spreading and cellular force. FAs mediate the cross-talk between the cytoskeleton and the extracellular matrix during migration. We found that the directional cell migration towards a stiffness gradient-durotaxis is hampered upon LIMD1 deficiency. Intriguingly, LIMD1 selectively recruits late but not early FA proteins through phase separation. We further discover that vinculin may act as an anchor for LIMD1 phase separation under force. Our data suggest a model in which localization of LIMD1 to the FAs, triggered by mechanical force, serves as a phase separation hub for assembling and organizing late FA proteins, allowing for effective FA maturation and efficient cellular mechano-transduction.

P611/B626

The Architecture of Talin Reveals an Autoinhibition Mechanism.

D. Dedden[1], S. Schumacher[1], C. Kelley[1], M. Zacharias[2], C. Biertümpfel[1], R. Fässler[1], N. Mizuno[1]; [1]Max-Planck-Inst Martinsried, Munich, GERMANY, [2]Technische Universität München, Munich, GERMANY.

Focal adhesions (FAs) are protein machineries essential for cell adhesion, migration and differentiation. Talin is an integrin-activating and tension-sensing FA component directly connecting integrins in the plasma membrane with the actomyosin cytoskeleton. However, its regulation is poorly understood. Here, we show a cryo-EM structure of full-length talin revealing a two-way mode of autoinhibition. The actin-binding rod domains fold into a 15-nm globular arrangement that is further interlocked by the integrin-binding FERM head. In turn, the rod domains R9 and R12 shield access of the FERM domain to integrin and the phospholipid PIP2 at the membrane. This mechanism ensures synchronous inhibition of integrin-, membrane- and cytoskeleton-binding. We also demonstrate that compacted talin reversibly unfolds to a ~60-nm string-like conformation, revealing interaction sites for vinculin and actin. Our data explains how fast switching between active and inactive conformations of talin could regulate FA turnover, a process critical for cell adhesion and signaling.

P612/B627

Regulation of PARP-1 Localization by Phosphorylation at Ser ^{372} by ERK1/2.

R. Chen[1], L. Xie[1], Y. Fan[1], **C. Chung**[1,2]; [1]Tianjin University, Tianjin, CHINA, [2]Duke Kunshan University, Kunshan, CHINA.

The poly(ADP-ribose) polymerases-1 (PARP-1) is a highly abundant nuclear protein. Its nuclear functions in repairing DNA damages induced by various stress signals, including genotoxic and inflammatory

stresses, have been well studied. In contrast, limited studies have been done on a cytoplasmic role(s) of PARP-1. Our study focuses on the cytoplasmic role of PARP-1 during microglia activation. Using immunofluorescence microscopy and western blotting, we showed that PARP-1 is present in the cytosol of microglia cells stimulated and activated by LPS. PARP-1changes its localization between nucleus and cytoplasm and more PARP-1 is in the cytosol of activated microglia. This change of PARP-1 localization can be blocked by U0126, an ERK1/2 inhibitor. The role of ERK1/2 phosphorylation on Ser^{372} of PARP-1 in the regulation of PARP-1 activity has been reported, but it has never been linked to the regulation of PARP-1 localization. Cells transfected with GFP-$PARP\text{-}1^{S372E}$ show a high level of PARP-1 in the cytosol in the resting microglia. In contrast, GFP-$PARP\text{-}1^{S372A}$ shows almost exclusive localization in the nucleus even in activated microglia. These results suggest a novel regulatory mechanism underlying cytoplasmic localization of PARP-1 by ERK1/2. We also demonstrated a novel function of cytoplasmic PARP-1 in regulating focal adhesion (FA) disassembly. In resting microglia, co-localization between paxillin, a main component of FA, and cytoplasmic PARP-1 was observed in resting microglia. Increased cytoplasmic PARP-1level induced by LPS was accompanied by focal adhesion assembly. These results suggest that PARP-1 localization change have a regulatory effect on FA disassembly, which may further regulate cell motility upon microglia activation.

Development of an Invadosome Inhibitor for Cancer Cell Metastasis Suppression.

Y. Su, M. Chuang, Y. Liu; National Taiwan University, Taipei, TAIWAN.

Invadosome, a term composed of invadopodia and podosome, is an actin-rich structure featured with ECM degradation ability. Depending on different cell types, invadosomes participate in various cellular functions, including migration of immune cells, bone resorption of osteoclasts, and especially the metastasis of cancer cells. Tks5, which contains a PX domain and five SH3 domains is a critical regulator for invadosome formation. In invadosomes, Tks5 acts as a scaffold that the PX domain determines the localization of invadosomes, and the SH3 domains recruit actin polymerization proteins such as N-WASP and Grb2 to invadosomes. Previous studies have shown that overexpression of Tks5ΔPX, a truncated protein lacking PX domain, could inhibit invadosome formation; therefore, it is unclear whether any one of these five SH3 domains could inhibit invadosome formation. In this study, we are aiming to develop an invadosome inhibitor to attenuate the invasion ability of cancer cells. Surprisingly, we found that overexpression of two SH3 domains could effectively inhibit invadosome formation in NIH3T3 c-Src cells. Besides, we generated the cell-penetrating peptide fusion proteins for SH3 proteins delivery. To further analyze the effect of SH3 proteins treatment on the invadosome functions and other cellular processes such as endocytosis, we will perform the ECM degradation assay, invasion assay, and transferrin uptake with the human breast cancer cells, MDA-MB-231. We hypothesize that single SH3 domain from Tks5 could be utilized as a potent invadosome inhibitor.

Modular Actin Nano-architecture Enables Podosome Protrusion and Mechanosensing.

K. van den Dries[1], L. Nahidiazar[2], J. A. Slotman[3], E. Pandzic[4], A. B. Houtsmuller[3], P. W. Wiseman[5], K. Jalink[2], **A. Cambi**[1]; [1]Radboud UMC, RIMLS, Nijmegen, NETHERLANDS, [2]The Netherlands Cancer Institute, Amsterdam, NETHERLANDS, [3]Erasmus MC, Rotterdam, NETHERLANDS, [4]University of New South Wales, Sydney, AUSTRALIA, [5]McGill University, Montreal, QC, CANADA.

Basement membrane transmigration during embryonal development, tissue homeostasis and tumor invasion relies on invadosomes, a collective term for invadopodia and podosomes. An adequate structural framework for this process is still missing. Here, we reveal the modular actin nano-architecture that enables podosome protrusion and mechanosensing. The podosome protrusive core contains a central branched actin module encased by a linear actin module, each harboring specific actin interactors and actin isoforms. From the core, two actin modules radiate: ventral filaments bound by vinculin and connected to the plasma membrane and dorsal interpodosomal filaments crosslinked by myosin IIA. On stiff substrates, the actin modules mediate long-range substrate exploration, associated with degradative behavior. On compliant substrates, the vinculin-bound ventral actin filaments shorten, resulting in short-range connectivity and a focally protrusive, non-degradative state. Our findings redefine podosome nanoscale architecture and reveal a paradigm for how actin modularity drives invadosome mechanosensing in cells that breach tissue boundaries.

P615/B630

Macro-based an alysis of Podosomes, Their Components and Contact by Microtubule +tips.

R. Herzog[1], K. Weber[1], K. van den Dries[2], P. Cervero[1], **S. Linder**[1]; [1]University of Clinic Eppendorf, Hamburg, GERMANY, [2]Radboud University, Nijmegen, NETHERLANDS.

Podosomes are actin-based adhesion and invasion structures in a variety of cell types, with podosome-forming cells displaying up to several hundreds of these structures. Podosome numbers, distribution and composition can be affected by experimental treatments or during regular turnover, necessitating a tool that is able to detect even subtle differences in podosomal properties. Here, we present a Fiji-based macro code termed “Podji” (“podosome analysis by Fidji”), which serves as an easy-to-use tool to characterize a variety of cellular and podosomal parameters, including area, fluorescence intensity and relative enrichment of associated proteins. This tool should be useful to gain more detailed insight into regulation, architecture and functions of podosomes. Moreover, it should be easily adaptable for the analysis of other micron-size punctate structures such as the podosome-related metalloproteinase islets, invadopodia, or focal complexes. This poster describes the work flow of the Podji macro, presents several examples of its applications, and also points out limitations, as well as adaptable features to streamline the analysis. We also present a second macro that is used to quantitatively analyse the contact of microtubule +TIPs with podosomes. Combining a tracking approach with +TIP detection in live cells, we analyse the impact of +TIP/microtubule contacts on the delivery of vesicle cargo to and accumulation at podosomes. In particular, we investigate i) the role of the ring structure as a potential docking site for MT1-MMP vesicles, and ii) the impact of actomyosin-generated forces regulated by the podosome cap on +TIP tethering at the ring, on substrates of different stiffness.

P616/B631

Investigating the Role of Specc1l Drosophila Homolog, Split Discs, in the Regulation of Non-muscle Myosin II Contractility.

A. Teran, J. Jung, A. Platenkamp, D. A. Applewhite, 97202; Reed College, Portland, OR.

Point mutations to sperm antigen with calponin homology and coiled-coil domain 1 like (SPECC1L), have been associated with a spectrum of crainio-facial disorders including Tessier type IV clefts, Oblique facial clefts, Opitz G/BBB syndrome, and Teebi hypertelorism all of which commonly share pathologies such as cleft palate or lip, hypertelorism (wide- spaced eyes), and defects of larynx, and esophagus [2,3,4].

These phenotypes are suggestive of defects in the migration and adhesion of neural cranial crest (NCC) cells [1]. Interestingly, morpholino knock-out of the zebrafish homolog of SPECC1L led to defects in the formation of head and jaw structures, and depletion of the Drosophila homolog of SPECC1L, Split Discs (SPDS), led to defects in the formation of the proboscis and blistering in wings [1]. Collectively, these phenotypes are indicative of defects in cellular adhesion and migration. In mammalian cells, SPECC1L co-localized with both actin and microtubules, and as such was hypothesized function as a cytolinker [1,5]. When we expressed SPDS in Drosophila S2 cells we observed a localization pattern more consistent with nonmuscle myosin II (NMII). Given this potential localization we hypothesized that SPDS may affect cell migration through the regulation of NMII contractility. To test these hypotheses, we carried out a series of colocalization experiments between SPDS and NMII, including point mutations analogous to those associated with cranial-facial disorders in humans. Furthermore, we used a migratory Drosophila cell line (D25) and tracked focal adhesion dynamics. We found that the phosphorylation status of SQH had no effect on the association between SPDS and SQH, while point mutations to SPDS did. Our data indicate that SPDS does colocalize with NMII, with the point mutation Q266P showing the highest degree of colocalization while G915S showed the lowest. We also found that while depletion of SPDS by RNAi had no effect of focal adhesion assembly rates, however, the rates of focal adhesion disassembly were slowed. Furthermore, the overall rate of cell migration was also decreased following depletion of SPDS, suggesting that this delay in focal adhesion disassembly may be affecting cell migration. We conclude that SPDS localizes to NMII and that it plays a role in focal adhesion dynamics that may be mediated by this interaction.

Signaling Networks Governing Cell Migration

P617/B632

Mechanisms of Sema-5c Signaling during Collective Cell Migration in the *Drosophila* Follicular Epithelium.

M. An derson, S. Horne-Badovinac; University of Chicago, Chicago, IL.

The collective migration of cells is a critical process during development, wound healing, and cancer metastasis. We study the highly coordinated collective migration of follicular epithelial cells in the *Drosophila* egg chamber. These cells utilize planar polarized signaling proteins to coordinate their migration, which is required to create the ovoid shape of the egg; follicle cells that do not migrate produce round eggs. Recent work in our lab has identified a relatively understudied transmembrane semaphorin, Sema-5c, as a novel regulator of migration. However, the molecular details of how Sema-5c regulates migration are unknown. Normal migration involves the extension of actin-rich protrusions only from the leading edge of each cell. Through live imaging, we have observed the extension of protrusions from the plasma membranes at not only leading edges, but also trailing edges in egg chambers lacking Sema-5c. We have also begun to characterize the role of a putative downstream target of Sema-5c, the small GTPase Rap1, in follicle cells during migration. Expression of a constitutively active form of Rap1 ($Rap1^{CA}$) produces moderately round eggs, which is strikingly similar to the shape of *Sema-5c* null eggs. Furthermore, we find that egg chambers expressing $Rap1^{CA}$ have slowed migration rates, suggesting that Rap1 has some function in follicle cell migration. Indeed, Rap1 is found at the basal surface of cells, where the molecular machinery controlling migration is located. Finally, we have taken advantage of the fact that egg chambers null for *Sema-5c* produce moderately round eggs that are neither fully elongated nor completely round to conduct an enhancer/suppressor screen. Previous work has shown that

removal of the receptor protein tyrosine phosphatase Lar, another regulator of migration in follicle cells, suppresses the *Sema-5c* egg shape defect. We are currently screening the left arm of the second chromosome, which contains about 20% of the *Drosophila* genome, using large deletions to tile across the entire arm. Though this screen, we aim to identify new proteins that interact with the Sema-5c signaling system and that may have roles in regulating migration.

P618/B633

Cell Confinement Reveals a Branched-actin Independent Circuit for Neutrophil Polarity.

B. R. Graziano[1], J. P. Town[1], E. Sitarska[2], T. L. Nagy[1], M. Fošnarič[3], S. Penič[3], A. Iglič[3], V. Kralj-Iglič[3], N. S. Gov[4], A. Diz-Muñoz[2], O. D. Weiner[1]; [1]UCSF, San Francisco, CA, [2]EMBL, Heidelberg, GERMANY, [3]University of Ljubljana, Ljubljana, SLOVENIA, [4]Weizmann Institute, Rehovot, ISRAEL.

Migratory cells use distinct motility modes to navigate different microenvironments, but it is unclear whether these modes rely on the same core set of polarity components. Here, we address this question by dissecting the role of branched actin assembly in the neutrophil polarity program. We use CRISPR-mediated genome editing in human neutrophils to knock out either the Arp2/3 complex, the nucleator of branched actin assembly, or its key activator the WAVE complex, which promotes branched actin assembly at the leading edge of migratory cells. We find that during unconfined migration, Arp2/3 and WAVE complex are each required for the mechanical force generation that supports long-range negative feedback and restriction of protrusion growth to one location. However, each complex is dispensable for polarity and movement of confined cells, where cell-extrinsic mechanical forces can compensate for the cell-intrinsic forces normally produced by WAVE complex. This confined movement relies on a completely different mode of leading-edge advance, with processive bleb-based protrusions forming in a back-and-forth motion that extends the leading edge in a serpentine manner. Surprisingly, these serpentine protrusions coincide with Rac-based local positive feedback loops that set a permissive zone for bleb propagation, operate independently of branched actin assembly, and form a mechanistically distinct polarity circuit in this context. Finally, we find that the long-range inhibitor that underlies competition between protrusions does not always respond to membrane tension directly but may rely on closely linked properties such as global cell shape and local membrane curvature. Our work reveals a hidden circuit for neutrophil polarity and indicates that cells have distinct molecular mechanisms for polarization that dominate in different microenvironments.

The Ca^{2+}Channel ORAI1 Is Essential for Lamellipodia Formation and Directional Persistence in Osteosarcoma U2OS Cells.

N. Espinosa-Bermejo, A. M. Lopez-Guerrero, I. Sanchez-Lopez, C. Pascual-Caro, E. Pozo-Guisado, **F. J. Martin-Romero**; University of Extremadura, School of Life Sciences, Badajoz, SPAIN.

Cell migration requires coordinated regulation of the cortical cytoskeleton to promote the generation of plasma membrane protrusions at the leading edge that allows the formation of focal adhesions and cell progression. Epithelial tumor cells are dependent on the formation of persistent and polarized lamellipodia that allows directed cell migration. To generate lamellipodia, a protein complex known as the WAVE regulatory complex (WRC) promotes the assembly of actin filaments to push the front of the cell forward. This process is cyclic and the continuous formation and severing of actin filaments, known as plasma membrane ruffling, is dependent on Ca^{2+} influx. In order to determine the extracellular Ca^{2+}

entry route that allows this reorganization of the cortical cytoskeleton, we have studied the possible participation of the plasma membrane Ca^{2+} channel ORAI1 in this event. We have found that ORAI1 co-localizes and co-precipitates with WRC members in response to the activation of the small GTPase RAC1, an upstream activator of the WRC and downstream mediator of epidermal growth factor, EGF. By subcellular localization of ORAI1-GFP, we have found that RAC1 stimulates the translocation of ORAI1 to the leading edge increasing its externalization. This RAC1-dependent stimulation promoted the formation of lamellipodia, increased protrusions persistence and played a key role in cell directness, features that were sensitive to the pharmacological inhibition of RAC1 with NSC 23766. The genomic edition of U2OS cells to generate a U2OS ORAI1-KO cell line confirmed that ORAI1 mediates the influx of Ca^{2+} at the leading edge, as KO cells showed reduced lamellipodia, persistence, and directness in a random cell migration assay. Finally, we have demonstrated that ORAI1 has a role in the disassembly of F-actin and that this Ca^{2+} channel was essential for the binding of gelsolin to F-actin, a set of results that explain the reason for the need for ORAI1 at the leading edge.Funded by grants BFU2007-82716 (Spanish Ministerio de Ciencia, Innovacion y Universidad), IB16088 and GR18084 (Junta de Extremadura). All these grants were co-funded by European Regional Development Funds (ERDF/FEDER).

Store-operated Calcium Drives Calcium Sensor and Channel Trafficking to Regulate Filopodia.

C. A. Heckman, M. L. Cayer, O. M. Ademuyiwa; Bowling Green State University, Bowling Green, OH.

Filopodia are sensors for signals in the cell's microenvironment and set the direction for cell motility in several cell types. The experimental elevation of intracellular Ca^{2+} level could initiate either extension or retraction in the most widely used model system, the axonal growth cone. Here, calcium content and filopodia dynamics are investigated using conditions under which chemotactic and haptotactic gradients are obviated. Removal of serum caused an increase in filopodia, which was enhanced several-fold by simultaneous endoplasmic reticulum (ER) stress with cyclopiazonic acid. Whereas these increase in filopodia was transient, cytoplasmic calcium, $[Ca^{2+}]_i$, increased continuously during net filopodia retraction. Inhibitors of calpain or calmodulin canceled the return of filopodia to the starting point, so both of these proteins were negative effectors of Ca^{2+} signaling. Restoration of external Ca^{2+} caused a persistent increase in filopodia which was blocked by transient potential canonical (TRPC) channel inhibitors but not voltage-gated calcium or Ca^{2+} release-activated channel (CRAC) inhibitors. Immunofluorescence localizations of stromal-interacting molecule (STIM), Orai, and TRPC suggested they resided in different compartments in untreated cells. All three proteins were also in loci with different radii. Orai became localized with STIM at the cell surface during ER depletion. Clusters of TRPC1 were found on microtubules or free in the peripheral cytoplasm in untreated cells, but appeared as a continuous layer at the surface during ER refilling. The data suggested that the effects of high internal Ca^{2+} were opposite during ER depletion and refilling. The Ca^{2+} influx caused formation of TRPC-STIM complexes at the cell surface and promoted filopodia growth. The prevalence of filopodia was further increased by a Ca^{2+}/calmodulin inhibitor. The results suggest that calcium-dependent suppression of filopodia is overcome by Ca^{2+} influx and exocytosis of TRPC channels.

P621/B636

Local Ca^{2+} Signaling Via a Stretch-activated Channel Trpv4 Facilitates Lamellipodial Protrusions and Orchestrates Directional Cell Migration.

E. Iu, A. Bogatch, S. Plotnikov; University of Toronto, Toronto, ON, CANADA.

Many biological processes, such as tissue morphogenesis and immune responses, require a coordinated, directional cell movement. To move directionally, cells require precise spatiotemporal regulation of force-generating components, e.g. Actin and myosin, focal adhesions, and regulatory proteins. Ca^{2+} is an important regulator of cell migration as indicated by the necessity of Ca^{2+} for cell polarization and protrusion-retraction cycles. Moreover, the dynamics of Ca^{2+} signaling have been shown to correlate spatiotemporally with lamellipodial protrusion events. Yet, it remains unknown which specific Ca^{2+} channel(s) control the structure and dynamics of cell lamellipodia and what molecular players are involved in this regulation.Using a genetically-encoded calcium biosensor, we showed that Ca^{2+} is enriched at the protruding edge of migrating fibroblasts. Inhibiting Ca^{2+} signaling was found to suppress lamellipodia extensions, perturb protrusion-retraction cycles of lamellipodia and impede cell migration. By combining siRNA gene silencing and cell spreading assay, we identified a mechano-gated Ca^{2+} channel TRPV4 as a prominent regulator of lamellipodia extension. We showed that TRPV4 is enriched in lamellipodia, suggesting that TRPV4 may regulate Ca^{2+} signaling at the cell edge. Inhibiting TRPV4 was found to decrease Ca^{2+} level at the protruding edge. To determine if TRPV4-mediated Ca^{2+} signaling regulates protrusion dynamics, we employed live-cell imaging and quantified the frequency and speed of protrusions. We found that suppression of TRPV4 resulted in slower and less frequent protrusions, suggesting that cell protrusion machinery is defective. Immunostaining of TRPV4-suppressed cells showed lower densities of actin network and nascent adhesion in lamellipodia.To understand the molecular link between TRPV4-dependent Ca^{2+} events and protrusions, we used an optogenetic inhibitor of Ca^{2+}/calmodulin-dependent protein kinase (CaMKII), a key Ca^{2+} signaling hub in many cell types. We found that local inhibition of CaMKII led to a significant reduction in the frequency and speed of protrusions, similar to those in TRPV4-suppressed/depleted cells. Inhibiting CaMKII showed a similar phenotype, suggesting that CaMKII is the mediator of Ca^{2+}-regulated cell protrusions. To determine the role of TRPV4-mediated Ca^{2+} signaling in directed cell migration, we assessed the speed and directionality of cell movement when either TRPV4 or CaMKII was suppressed and found that cell migration was impaired in both conditions.Together, these data unravel a new signaling axis composed of TRPV4/CaMKII, which regulates the structure and dynamics of protruding cell edge, enhances the efficiency of the protrusion machinery and orchestrates directed cell migration.

P622/B637

The Cadherin Fat2 Organizes a Planar Signaling System That Directs Actin Protrusion and Collective Migration of Epithelial Cells.

A. M. Williams, S. Horne-Badovinac; University of Chicago, Chicago, IL.

Cells migrating as a collective need to ensure that their leading and trailing edges align with their neighbors, a form of planar cell polarity. We study how a novel planar cell polarity system in the Drosophila egg chamber epithelium coordinates one such collective migration. The follicle cells that make up the egg chamber epithelium undergo a highly coordinated collective migration along an underlying basement membrane extracellular matrix. The tissue lacks leader cells, and tissue-level polarity emerges from cell-cell interactions across the field. We show that Fat2, an atypical cadherin that

localizes to the trailing edge, promotes lamellipodial protrusion by recruiting the Wave complex to clusters at the leading edge of the cell behind. Fat2 also recruits Lar and Sema-5c, two transmembrane signaling proteins, to these leading edge clusters to form a planar-polarized intercellular signaling complex. Key next questions include 1) How does the Fat2 signaling complex organize asymmetrically across cell-cell junctions and 2) How does polarity information propagate across the cell field?

The Role of ERalpha36 and GPR30 receptors in the Estrogen Signaling in Inflammatory Breast Cancer.

X. S. Bittman Soto[1], E. A. Peterson[1], J. Perez-Santiago[1,2]; [1]University of Puerto Rico, San Juan, PR, [2]UPR Comprehensive Cancer center, San Juan, PR.

Inflammatory Breast Cancer (IBC) is a rare and very aggressive type of breast cancer; reporting a rapid progression and a poor prognosis compared to other subtypes of breast cancer. Approximately ~40% of IBC cases are classified as triple negative breast cancer (TNBC), due to the absence of hormone receptors and HER2 receptor; for which there is still no effective targeted therapy available. Estrogen (E2) have been found to enhance the migration and invasion phenotypes of IBC cell lines; by activating a novel cytoplasmic receptor (ERα36 isoform) and a membrane localized G-protein receptor (GPR30). However, this mechanism is not well characterized in IBC. Here, we evaluated the transcriptome changes in IBC cells upon exposure with E2 and/or GPR30 receptor inhibitor (G15). We hypothesized that ERalpha36 and GPR30, upon exposure with E2, are necessary to conduct transcriptome regulation in IBC cells; enhancing its oncogenic phenotypes. **Methods:** We performed Immunofluorescence microscopy and RNA-seq assay in these 4 study groups; ETOH-treated, E2-treated, G15-treated and E2-G15-treated IBC cell line SUM149PT (classified as TNBC), for ERα36 and GPR30 receptor detection and localization, and to identify specific transcriptome changes associated with oncogenic phenotypes. **Results:** Inhibition of receptor GPR30 was associated with biological processes such as: cell-cell adhesion via plasma-membrane adhesion molecules, regulation of membrane potential, and peptide hormone metabolism (adjusted p-value <0.01), among others. These results suggest that GPR30 is involved in the regulation of genes associated with the oncogenic phenotypes in IBC. Furthermore, by IF, we suggest ERα36 can translocate into the nucleus upon activation with E2. Data acquired from these experiments will contribute to the better understanding of IBC molecular signature and create new opportunities to develop novel targeted therapies. Non-canonical Wnt Signaling Promotes Stem Cell Migration in the *Drosophila* Intestinal Epithelium.

D. Hu, J. Yun, J. Elstrott, H. Jasper; Genentech, Inc., South San Francisco, CA.

Adult stem cells play crucial roles in the maintenance and repair of high-turnover tissues. In multiple tissues, stem cells respond to damage and migrate from their current niche to the site of injury, proliferating or differentiating to replace lost cells. As such, stem cell migration must be carefully regulated to enable proper regeneration without disrupting the stem cell niche during homeostasis. In the *Drosophila* intestine, we find that intestinal stem cells (ISCs) are largely static under homeostatic, unchallenged conditions, but undergo lamellipodium formation and cell migration after intestinal damage by *Ecc15* bacterial infection or laser ablation. We find that this process is actin-dependent, and

regulated by non-canonical Wnt signaling. ISC migration is blocked after inhibiting Myosin II activity by blebbistatin treatment, or disrupting the actin-associated proteins, Dia and the Arp complex. Depletion of Otk (Ptk7 in mammals), a transmembrane protein in the non-canonical Wnt pathway, and its interactor, Dishevelled (Dsh/Dvl), prevents ISC migration after tissue damage, while overexpression of Otk and Dsh was sufficient to promote lamellipodium formation in unchallenged conditions. We also observe that depletion of Otk or Dsh decreases mitotic numbers, suggesting an additional role of these proteins in ISC proliferation. Altogether, we find that ISCs migrate in response to damage, and our data support a role for non-canonical Wnt signaling in regulating this behavior.

P625/B640

Negative Surface Charge Defines the State of Cell Cortex and Regulates Excitable Dynamics in Amoeboid Migration and Macropinocytosis.

T. Banerjee[1], D. Biswas[2], D. S. Pal[1], Y. Miao[1], P. A. Iglesias[2], P. N. Devreotes[1]; [1]Department of Cell Biology, Johns Hopkins University School of Medicine, Baltimore, MD, [2]Department of Electrical and Computer Engineering, Johns Hopkins University, Baltimore, MD.

The spatially distributed components of signal transduction excitable network (STEN) and cytoskeletal excitable network (CEN) in Dictyostelium and leucocyte cells generate autonomous waves in the substrate attached basal surface. One key event in this characteristic cortical wave formation is the symmetry breaking of membrane phospholipids and self-organization of STEN and CEN proteins to dynamically generate distinct regions in the cell cortex which corresponds to the typical front (or “activated”) and back (or “inactivated”) regions of a randomly migrating cell. An analogous pattern of organization is observed in chemotactic migration, micropinocytosis, phagocytosis, and cytokinesis of different types of eukaryotes cells. We have identified two novel unexpected features of these self-organizing patterns. First, we have found that three lipidated membrane proteins in Dictyostelium, PKBR1, Gßγ, and RasG, which are widely thought to be uniformly distributed over the membrane, show preferential localization in the back/inactivated regions of cell cortex. Our data indicates that besides conventional recruitment based mechanism used by many other components, a dynamic partitioning process may contribute to the self-organization pattern of components that remain associated with the membrane. Second, we have assessed the localization of the generic surface charge sensor that was previously shown to be tightly associated with the negatively charged inner surface. In Dictyostelium and RAW 264.7 cells, we found that the sensor partitioned to the back/inactivated region as did the lipidated proteins. Our data suggested that high negative surface charge defines the back or inactivated region of the cell cortex and the cell migration and macropinocytosis processes are essentially guided by the alteration of surface potential on the inner leaflet to generate dynamic polarity.

P626/B641

Genetic Screening for Novel Partners of an Adhesion Regulator - Kinase Responsive to Stress B (KrsB).

A. Khan, S. Ratnayake, Y. Artemenko; SUNY Oswego, Oswego, NY.

Dictyostelium discoideum social amoeba is a well-established model organism for the study of amoeboid-type migration, which is the type of movement seen in neutrophils and metastatic cancer cells. Cycling between active and inactive forms of the serine/threonine kinase responsive to stress B (KrsB), a homolog of mammalian tumor suppressor MST1/2 and Drosophila Hippo, contributes to the dynamic regulation of cell adhesion that is needed for proper cell adhesion and chemotaxis in D.

discoideum. However, the exact mechanism by which KrsB affects the cell's ability to adhere is unclear. The goal of this project is to find new regulators or effectors of KrsB using a genetic suppressor screen. Cells lacking KrsB were transformed with a cDNA library and mutants that exhibited either a rescue or an enhancement of the original phenotype were isolated. Cells lacking KrsB have a distinct phenotype when they form plaques on a bacterial lawn, with an enlarged region of cells in streams and an uneven expanding front of vegetative cells, which makes krsB$^-$ plaques appear to have rough edges. During the first round of screening, 150 plaques were identified, 48 of which showed a phenotype that was different from krsB$^-$: 30 plaques had smooth round edges similar to wild-type or cells rescued with KrsB, and the rest had phenotypes that differed from krsB$^-$ or wild-type cells, such as plaques that completely lacked aggregating cells. Thus, the first round of screening demonstrated that the cDNA library may provide genes that can compensate for the lack of KrsB. Efforts are underway to expand our collection of mutants and to isolate plasmids with the cDNA library inserts to identify the genes responsible for the rescue of the krsB$^-$ phenotype or for making the phenotype more severe. Identification of these genes will give us a better understanding of the molecular mechanism of KrsB function in cell adhesion and migration.

P627/B642

Integrating Neutrophil Fronts and Backs with the Mtorc2 Mechanotransduction Pathway.

S. Saha, O. D. Weiner; Cardiovascular Research Institute and Department of Biochemistry and Biophysics, UCSF, San Francisco, CA.

Neutrophils leverage feedback between mechanical forces and biochemical signaling to guide their polarity and motility during immune surveillance. For efficient movement, cells need to establish a single leading edge. We recently found that tension-based communication between actin protrusions (relayed by the PLD2/ mTORC2 pathway) are responsible for long-range competition between protrusions for proper control of polarity and movement. mTORC2 is an evolutionarily conserved regulator of cellular growth, proliferation and metabolism. Surprisingly, this signaling node has been co-opted for mechanochemical regulation of membrane homeostasis and cellular polarity or motility in systems ranging from yeast to Dictyostelium to neutrophils. Here we probe the molecular logic of how mTORC2 regulates the motility machinery. The kinase activity of mTORC2 is the most well-characterized route of regulating downstream effectors, but the complex is also thought to scaffold recruitment of some effectors in a kinase-independent fashion. Which of these activities links mTORC2 to the motility machinery is not well understood. Here we investigate this question using a combination of genetic and pharmacological approaches to selectively impair the kinase-dependent versus independent signaling roles of the complex. We find that the tension-based inhibition of Rac activation that enables competition between protrusions is gated by the kinase-independent role of the complex, whereas the mTORC2 kinase arm is essential for regulation of Myosin II activity at the trailing edge. With live cell imaging and Rac/Rho biosensors, we show the necessity of both of these branches of mTORC2 signaling for leading and trailing edge organization, cell polarity, movement, and guidance. Our results show how stretch activates the kinase dependent and independent arms of mTORC2 to integrate both the front (Rac) and back (Rho) polarity programs during neutrophil motility.

P628/B643

A Mechanistic Model of PLC/PKC Signaling Implicates Phosphatidic Acid as a Key Amplifier of Chemotactic Gradient Sensing.

J. L. Nosbisch[1], A. Rahman[1], K. Mohan[1], T. C. Elston[2], J. E. Bear[3,2], J. M. Haugh[1]; [1]North Carolina State University, Raleigh, NC, [2]University of North Carolina School of Medicine, Chapel Hill, NC, [3]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC.

Chemotaxis of fibroblasts and other mesenchymal cells is critical for embryonic development and wound healing. Fibroblast chemotaxis directed by a gradient of platelet-derived growth factor (PDGF) requires signaling through the phospholipase C (PLC)/protein kinase C (PKC) pathway. Diacylglycerol (DAG), the lipid product of PLC that activates conventional PKCs, is focally enriched at the up-gradient leading edge of fibroblasts responding to a shallow gradient of PDGF (Asokan et al., PMID 25482883), suggesting that an internal amplification mechanism is at play. In previous work, a mechanistic, reaction-diffusion model of the PLC/PKC signaling pathway was developed to identify possible mechanisms responsible for signal amplification (Mohan et al., PMID 28700916). We found that phosphorylation of myrisotylated alanine-rich C kinase substrate (MARCKS) by membrane-localized PKC constitutes a positive feedback loop sufficient for local amplification of DAG and active PKC at the leading edge. However, by itself, the MARCKS feedback only weakly amplifies the signal in shallow PDGF gradients, and the system lacks robustness to modest changes in the midpoint concentration of PDGF. The new model includes phosphatidic acid (PA), a lipid intermediate in the metabolism of DAG, identifying roles in two other positive feedback loops. Model simulations show that the MARCKS feedback mechanism synergizes with these new feedback loops to polarize PKC signaling in response to shallow PDGF gradients and over an appreciable range of midpoint PDGF concentrations. DAG kinases and phospholipase D, the enzymes that produce PA, are implicated as key regulators, and testable predictions related to perturbation of DAG kinase activity are most promising.

Novel Extraction Method of Molecular Activity Patterns Controlling the Cell Morphological Changes Based on Reverse Correlation an alysis.

K. Kunida, Y. Sakumura; Nara Institute of Science and Technology, Ikoma Nara, JAPAN.

Cell migration are one of the important biological phenomena related to various biological functions. The molecular mechanisms of cell migration have been extensively studied in tissue culture cells. Rho GTPases (Rac1, Cdc42, RhoA) have been identified as key regulators of cell migration(Alan Hall *Science*,1998). In previous work, we have measured and quantified the spatio-temporal signals of Rho GTPase activity and cell morphological change in migrating HT1080 cell by using the FRET imaging and quantitative imaging analysis. Furthermore, we have uncovered the relative timing between Rho GTPase activity and morphological change based on the time-shifted cross-correlation analysis (K Kunida et al., *J Cell Sci*, 2012). Cross-correlation analysis is powerful tool for investigating the relative timing between signals. But there are several concerns; (i)The dynamic relationship between signals cannot be seen in cross correlation. (ii)The obtained cross-correlation coefficient is very small (it is around 0.5 in our and other groups research). (iii) Positive or negative of the shift time at which the correlation coefficient is maximum does not necessarily indicate a causal relationship. From the above, this study proposes a new data analysis method for extracting dynamic relationship from sequential data of Rho GTPases activity and cell morphological change. In this study, we propose Motion-Triggered Average (MTA) as a method

to extract time-series data of molecular activity that control the specific pattern of morphological change based on reverse correlation analysis. Specific sequence patterns of resulting morphological changes are defined, and the average of molecular activity data having the same relative time to each morphological change is calculated to obtain molecular activity information from which noise is removed. As the result, we extracted the time-series of Rho GTPase activities corresponding to 4 typical cell migration patterns (wavelike-protrusion or retraction, directed-protrusion or retraction) with MTA analysis. Comparing with the random sampling, MTA analysis could extract signals with high similarity despite the different cell. Finally, we performed the Principle Components an alysis (PCA) for MTA-identified signals of Rho GTPase activities and confirmed that MTA analysis could identified distinct patterns of Rho GTPase activities.

Myosin IIA and Pi3k Are Important for the Basal Protrusion of Nrk52e Ras^{V12} Cells during Cell Competition.

I. Jebri, T. Itoh; Kobe University, Kobe, JAPAN.

Cell competition describes a process by which a small number of unfit cells are eliminated by a vast majority of surrounding cells. In mammalian cells, the outcome of cell competition was mainly the apical extrusion of unfit cell from the cell layer. For the last decade, MDCK were the only mammalian cells used for the study of cell competition. Therefore, it is not known if this process occurs also in other mammalian cells. In this study, we show that cell competition can occur also in Normal Rat Kidney 52E epithelial cells (NRK52E). Interestingly, unlike the apical extrusion often observed in MDCK Ras^{V12} cells (unfit cells) surrounded by WT MDCK cells, NRK52E Ras^{V12}cells behaved in a totally different manner. We first demonstrate that when NRK52E Ras^{V12}cells are surrounded by normal cells, Ras^{V12}cells become highly motile and are fragmented. An d we show that this process is apoptosis-independent. We also demonstrate that this movement happens beneath the layer of normal cells. Previously it has been demonstrated that the elevation of myosin IIA in MDCK Ras^{V12}cells during cell competition is important for the apical extrusion of these cells. Interestingly, the treatment of NRK52E Ras^{V12}surrounded by WT cells by the myosin inhibitor Blebbistatin significantly increased the number of extruded Ras^{V12}cells. Moreover, the Knockdown of Myosin IIA in Ras^{V12}cells showed a similar result. Previous study has also demonstrated that Myosin IIA activation affects E-cadherin/catenin complex. We interestingly found that the expression of E-cadherin was depleted when Ras^{V12}is activated. To further investigate the mechanism of cell competition in NRK52E cells, we tried to inhibit different effectors downstream of Ras such as PI3K, p38, ERK, JNK and ROCK. Myosin IIA is usually activated by ROCK but its inhibitor Y27632 didn't block the basal protrusion of Ras^{V12}. Instead, we found that the treatment of NRK52E cells by the PI3K inhibitor LY294002 significantly increased the apical extrusion of Ras^{V12}cells surrounded by WT cells. Moreover, we show that the level of P-Akt is increased in Ras^{V12}cells. However, the LY294002 treatment doesn't seem to significantly decrease the level of P-Akt. This study shows that cell competition can also occur in other mammalian cells and that in this model Myosin IIA and PI3K are important for the basal protrusion of NRK52E cells independent of P-Akt.

P631/B646

Analysis of Rho Gtpase Networks Using Gtpase-trap Reveals That Rac-induced Contractility Changes Cell Migration Behavior.

H. Lee; IBS, daejeon, KOREA, REPUBLIC OF.

The Rho GTPases, Rac1, Cdc42 and RhoA, coordinate cytoskeletal dynamics and regulate cell motility through binding to various effectors. There have been many efforts to identify interactions between Rho GTPases and their effectors so as to understand the molecular mechanisms underlying cell migration. However, obtaining a highly refined, large-scale network of Rho GTPases has been challenging because most previous interaction assays were performed at a single GTPase level using experimental methodologies and conditions that varied. In this report, we developed a super-sensitive, large-scale interaction-screening method for use in live cells called 'GTPase-Trap'. Utilizing this method, we demonstrate that Rac proteins strongly bind to ROCK (Rho-associated kinase) proteins, which have long been known as typical downstream effectors of RhoA. Perturbation of Rac-ROCK interactions revealed that the contractility induced by this interaction is essential for lamellipodia protrusion, arc stress fiber formation, focal adhesion regulation, and cell migration behavior. Thus, the molecular network of Rho GTPases identified by our method provides new insight into the underlying mechanisms by which these GTPases coordinate actin cytoskeleton, focal adhesion dynamics, and cell migration.

Modeling Cell Repolarization in Single Cells and in Cell-cell Contacts.

A. Buttenschoen, E. Rens, **L. Edelstein-Keshet, V6T 1Z2**; University of British Columbia, Vancouver, BC, CANADA.

What external stimuli makes a polarized cell de-polarize or re-polarize? Under what conditions would a motile cell undergo contact inhibition of locomotion (CIL) when it encounters another cell? Would colliding cells adhere, stall, reverse or move together? to address these questions, we extend a basic model for cell polarization due to Mori et al (2008) Biophys J 94: 3684. The model describes the spatio-temporal distribution of GTPase activity by a "wave-pinning" mechanism. We first analyze polarity robustness and show its dependence on the total amount of GTPase and the rates of (in)activation by GAPs/GEFs. We show that some cell states are robust and refractory to repolarization, whereas other states are highly sensitive. We then add bi-directional feedback between cell forces and GTPase activity, and show that our simulated repolarization closely resembles experimental data (from opto-genetic manipulations of GTPases, and cell-cell collisions in microfluidic channels). Simulations in 1D kymographs, as well as 2D motile cells (with the Cellular Potts Model) are presented. We explore various assumptions for the link between cell-cell forces and GTPase signaling and how those assumptions affect paired cell migration. Our theoretical and simulation studies pave the way to investigate the roles of forces and signaling in collective migration of cell-trains and epithelial sheets.

Rap1 Regulates Adhesion and Cytoskeletal Rearrangements during Embryonic Wound Healing.

K. E. Rothenberg, R. Fernandez-Gonzalez; University of Toronto, Toronto, ON, CANADA.

Collective cell movements contribute to embryonic development and tissue repair, as well as the spread of disease. Cells coordinate their migration through adhesion and cytoskeletal rearrangements, but how

these molecular rearrangements are regulated is not well understood. We investigate collective cell migration during wound healing in the *Drosophila* embryonic epidermis, a process in which cells coordinate their movements to rapidly seal a lesion. After wounding, cells immediately surrounding the lesion internalize cell-cell adhesion molecules from the wound edge, including the core adherens junction (AJ) proteins E-cadherin, alpha-, and beta-catenin. AJ proteins are subsequently redeployed to the former tricellular junctions at the wound edge. In parallel, the cells polarize their actomyosin cytoskeleton to form a supracellular cable around the wound. Formation of the actomyosin cable requires the redistribution of AJ components at the wound edge. Through a combination of contraction of the actomyosin cable and reinforced adhesion, cells coordinate their movements to promote rapid wound repair. However, the signals that initiate and coordinate the molecular rearrangements that drive wound closure are unclear. The small GTPase Rap1 is a mechanosensitive molecular switch that promotes cytoskeletal polarization during collective cell migration in *vivo*. Rap1 also regulates cell junction turnover and interacts with actin regulators. Thus, Rap1 may coordinate and integrate the junctional and cytoskeletal rearrangements that drive wound repair. We tracked the dynamics of Rap1 and E-cadherin localization during wound closure, and we found that Rap1 was rapidly depleted from the wound edge and localized to tricellular junctions, preceding the redistribution of E-cadherin. These data suggest that Rap1 may be necessary for the molecular rearrangements that drive embryonic wound closure. Rap1 depletion by RNAi slowed down wound repair by 47% relative to controls, indicating that Rap1 is important for rapid embryonic wound healing. Additionally, polarization of the molecular motor non-muscle myosin II at the wound edge was 49% lower upon Rap1 RNAi treatment, suggesting that Rap1 mediates formation of the supracellular actomyosin cable around the wound. Similar results were obtained by overexpressing a dominant-negative form of Rap1. Together, our data suggest that Rap1 plays an integral role in regulating the adhesion and cytoskeletal rearrangements required for cells to coordinate their migration during embryonic wound healing.

P634/B649

Genetic Interaction between Adhesion Regulators Rap1 and Kinase Responsive to Stress B in *Dictyostelium Discoideum*.

G. Niu, B. Fernandez, Y. Artemenko; SUNY Oswego, Oswego, NY.

Cell adhesion to the substrate influences a variety of cell behaviors and its proper regulation is essential for migration. Social amoeba *Dictyostelium discoideum* is an extensively and commonly used model organism, whose movement is very similar to that of other amoeboid cells, such as neutrophils and metastatic cancer cells. Although we know many components of the signal transduction network that regulate directed migration, details of the pathways regulating cell adhesion during migration are lacking. Rap1 is a small GTPase that regulates adhesion in Dictyostelium cells in part via its effects on myosin II and talin. Kinase responsive to stress B (KrsB), a homolog of mammalian tumor suppressor MST1/2 and Drosophila Hippo, also regulates cell adhesion and migration, although the molecular mechanism of KrsB action is not understood. Since KrsB has been shown to interact with active Rap1 by mass spectroscopy, we decided to investigate the genetic interaction between Rap1 and KrsB. Cells lacking KrsB have increased contact with the substrate and are difficult to detach from the surface, which leads to reduced movement. Expression of constitutively active $Rap1^{G12V}$ increased cell adhesion, and inactive $Rap1^{S17N}$ reduced cell adhesion even in the absence of KrsB, suggesting that Rap1 does not require KrsB to mediate cell adhesion. However, $Rap1^{S17N}$ reduced cAMP-induced KrsB phosphorylation, whereas expression of $Rap1^{G12V}$ raised basal KrsB phosphorylation, suggesting Rap1 regulates KrsB

activation. Surprisingly, chemoattractant-induced activation of Rap1, as assessed by transient cortical localization of the biosensor RalGDS, was impaired in *krsB*$^-$ cells, possibly due to increased basal activity of Rap1. Thus, Rap1 appears to activate KrsB, which may function in a negative feedback loop to shut off Rap1 signaling, allowing for precise regulation of cell adhesion during migration.

P635/B650

The Novel Role of Phosphatidylinositol-3,4-bisphosphate in Cell Migration.

X. Li, P. Devreotes; Johns Hopkins University School of Medicine, Baltimore, MD.

Cell migration mediates a large number of key physiological activities during development and in the adult. These processes require coordination of signal transduction and cytoskeletal events which display excitability. Phosphoinositides have played a prominent role in signal transduction networks involved in migration, but the mechanisms of excitability are poorly understood. Here we identified that cells maintain complementary spatial and temporal distributions of Ras activity and Phosphatidylinositol-3,4-Bisphosphate (PI(3,4)P2) during random migration and in response to chemoattractants. Whereas Ras is active in the front, PI(3,4)P2 is distributed in a back to front gradient. In addition, depletion of PI(3,4)P2 by disruption of the 5-phosphatase, Dd5P4, or by recruitment of 4-phosphatase INPP4B to the plasma membrane, leads to elevated Ras activity, cell spreading and altered migratory behavior. Interestingly, lagging edge component PI(3,4)P2 localizes to leading edge protrusions, such as nascent macropinosomes, in a temporally and spatially restricted manner. PI(3,4)P2 enriched macropinocytic vesicles are transported into the cytosol and then break apart into “satellites” vesicles. Furthermore, using the green-to-red photoconvertible system, we determined that PI(3,4)P2 diffuses towards the front, suggesting there is a source at the back. Based on these observations, we propose there might be a connection between the PI(3,4)P2 on the front macropinosomes and back-to-front gradient of PI(3,4)P2 during cell migration.

P636/B651

Fine Tuning of the an ionic Membrane Lipids PI(4,5)P2 and Phosphatidylserine Establishes Polarized Morphologies and Regulates Cell Migration.

M. Beshay, A. Schade, N. Bawazir, **C. Janetopoulos**; University of the Sciences, Philadelphia, PA.

Changes in cell morphology are critical for many cellular processes including cell division and the ability of cells to migrate. Many of the same signaling and cytoskeletal components regulate these morphological changes. Here we show that fine tuning of the plasma membrane (PM) PI(4,5)P2 levels and the rate of phosphatidylserine (PS) exposure contribute to a change in the charge of the inner leaflet of the PM and contributes to the feedback loops that set up polarized morphologies during migration. Synthetic lowering of PM PI(4,5)P2 levels below a threshold initiated positive feedback loops triggering actin polymerization and cell spreading. Conversely, raising PM PI(4,5)P2 levels significantly decreased cell speed and motility. Additionally, we demonstrate that PS is exposed on the outer leaflet of the PM in response to chemoattractants and after PI(4,5)P2 levels are lowered. This work shows for the first time a feedback loop between alterations in the PI(4,5)P2 pool on the inner leaflet and rates of PS exposure to the outer leaflet of the PM. Our work finds that there is a a gradient of PI(4,5)P2 in a polarized cell, with elevated levels at the rear. Taken together, these findings suggest that charge contributes to cell polarity, with migrating cells having a net loss of negative charge on the inner leaflet at the leading edge and an increase in negative charge at the rear of the cell.

P637/B652

Novel Role for Pikf in the Regulation of Pi(3,4)p_2 Dynamics.

E. Zhang, K. Zhangxu, J. Lee, M. Edwards; Amherst College, Amherst, MA.

Directed cell migration is essential to a range of events including early organismal development and immune function. Migration is controlled by the highly coordinated activities of the cytoskeletal and signal transduction cellular networks. Phosphoinositides, a network of phosphorylated inositol lipids, serve as key regulators of the signal transduction networks involved in migration. Uncovering the networks of kinases and phosphatases which regulate phosphoinositide biosynthesis is vitally important to our understanding of the networks that regulate migration. Phosphatidylinositol (3,4)-bisphosphate [PI(3,4)P_2] has been found to antagonize movement by limiting Ras activity in a mutually inhibitory feedback loop. However, the identity of the molecules involved in mediating this mutual inhibition have not been fully described. The depletion of Dd5P4, a 5-phosphatase that generates PI(3,4)P_2, results in only a partial suppression of cellular PI(3,4)P_2 levels, suggesting the involvement of other unidentified enzymes in PI(3,4)P_2 biosynthesis. Here, we describe a novel role for pikF, a putative 3-kinase in *Dictyostelium,* that contributes to the balance of PI(3,4)P_2 biosynthesis. We demonstrate that pikF is a critical regulator of cellular protrusiveness and directed cell migration. We propose that a mutually inhibitory relationship between Ras and pikF dependent PI(3,4)P_2 biosynthesis serves as the mechanism of pikFs role in migration. Furthermore, we identify an important role for the formin-generated cortical actin network in the regulation of pikF dynamics. Our work provides important insight into the regulation of the cellular dynamics of PI(3,4)P_2, which is itself emerging as a critical regulator of cellular protrusiveness and directed cell migration.

P638/B653

CD56 (NCAM) Regulates Actin Cytoskeletal Function in Human Natural Killer Cells.

A. L. Dixon[1], J. T. Gunesch[2], T. Ebrahim[3], E. Hegewisch Solloa[1], **E. M. Mace**[1]; [1]Columbia University Irving Medical Center, New York, NY, [2]Baylor College of Medicine, Houston, TX, [3]Barnard College, New York, NY.

Human natural killer (NK) cells are innate immune cells that are defined as being $CD56^+CD3^-$, however the functional role of CD56 (neural cell adhesion molecule, NCAM) on NK cells has not been described. We have previously shown that CD56 is required for human NK cell migration on developmentally supportive stromal cells. The objective of this study was to define the functional role of CD56 in regulating cell motility, adhesion and function in human NK cells. We deleted CD56 in two human NK cell lines using CRISPR-Cas9 gene editing and performed high- and super-resolution microscopy and scanning electron microscopy to define the effect of CD56 deficiency on the regulation of cell migration and the cytoskeleton. This was complemented by functional assays to measure the effect of CD56 deletion on lymphocyte effector function. We found that CD56 colocalizes with β1 integrin in the uropod of migrating NK cells, and that CD56 deficiency leads to impaired cell spreading. Cell migration in the absence of CD56 was inhibited due to impaired detachment of the cell uropod and actin architecture was highly deregulated. Structured illumination microscopy defined large actin asters at sites of focal adhesion proteins, suggesting that disassembly of integrin-mediated adhesion complexes is dysregulated. Impaired cell spreading was accompanied by increased filopodia length and disordered lamellipodia, underscoring the requirement for CD56 in actin polymerization and homeostasis. This was confirmed by scanning electron micrographs which revealed significantly longer filopodia and

deregulated membrane topology in resting cells in the absence of ligation; reconstitution of CD56 rescued these phenotypes. Finally, we tested immune synapse formation and NK cell lytic function. Despite the actin impairments in CD56-KO cells, they formed immune synapses with susceptible target cells but were unable to mediate target cell lysis due to impaired lytic granule exocytosis. This functional deficiency was accompanied by decreased phosphorylation and aberrant localization of the focal adhesion kinase (FAK) homologue Pyk2, a non-receptor protein tyrosine kinase that plays critical roles in lymphocyte migration and activation. Taken together, these data demonstrate a critical role for CD56 in human NK cell migration and function through modulation of Pyk2 signaling.

P639/B654

Pi-3 Kinase Drives Adaptive 3D Migration by Polarizing Large Pressure-based Protrusions.

E. Welf, M. Driscoll, A. Weems, K. Dean, R. Fiolka, G. Danuser; UT Southwestern Medical Center, Dallas, TX.

A hallmark of highly metastatic cells is the ability to navigate complex and diverse microenvironments. Cells with this capability often switch between motility modes, utilizing both actin-driven and pressure-driven protrusions to find or make empty spaces in dense extracellular matrices. In contrast to the belief that actin and pressure-based protrusion operate independently, we have discovered in this study that actin polymerization plays a critical role in reinforcing pressure-based protrusions to generate large blebs that push and remodel a 3D collagen network to create space for invading melanoma cells. We found that this localized protrusion reinforcement occurs through spatially restricted PI-3 Kinase (PI3K) signaling that drives actin polymerization through Rac1. By using a combination of high resolution light sheet microscopy along with 3D analytical tools, we show that regions of high PI3K create larger blebs. These blebs are reduced in size and redistributed in space under PI3K inhibition. By using photoactivatable forms of PI3K and Rac1, we found that bleb size can be increased by local activation of both PI3K and Rac1. Melanoma cells use these large pressure-based protrusions to dig tunnels through the soft but dense collagen network. Surprisingly, we found that this tunneling process does not require extracellular protease activity, but employs paxillin-containing adhesions along with repeated pressure-based “punches” to burrow through the network. Formation of adhesion structures at the front of these tunnels also localizes PI3K signaling to organize the large protrusions at the front of the cell where greatest contact occurs between adhesions and collagen. Classically, PI3K is thought to drive actin-based protrusion by recruiting Rac activators that generate a branched actin network. We also found actin inside growing blebs, suggesting that actin polymerization through Rac1 and PI3K drives bleb growth. This surprising result calls into question the very discrimination of actin-based and pressure-based protrusions and suggests that all protrusions may share common mechanisms. Furthermore, identification of PI3K as a common polarity cue explains how highly metastatic cells are able to switch protrusion mechanisms while maintaining directional polarity - cells use the same tools in different ways in order to switch protrusion mechanisms quickly when confronted with diverse microenvironments.

P640/B655

Let'S Stick Together: Defining the Molecular Mechanisms Underlying Chick Cranial Neural Crest Cell Epithelial to Mesenchymal Transition.

C. M. Gustafson, L. S. Gammill; University of Minnesota, Minneapolis, MN.

Neural crest cells (NCC) are a transient, multipotent vertebrate cell population that differentiates into a variety of crucial cell types including melanocytes, chondrocytes, neurons or glia. Early in development, NCC undergo an epithelial to mesenchymal transition (EMT) in order to migrate and colonize different tissues throughout an embryo. EMT requires drastic changes to cell polarity, cell-cell adhesion, and the cytoskeleton. Currently, the molecular mechanism by which NCC undergo EMT is incompletely understood. Previous work in the lab identified a four-pass transmembrane protein, Tetraspanin18 (Tspan18), that antagonizes EMT in chick cranial NCC by maintaining the epithelial adherens junction protein, Cadherin 6B (Cad6B). In order for EMT to occur, Tspan18 and Cad6B must be downregulated. While Tspan18 and Cad6B mRNA expression is extinguished prior to EMT, the fate of Tspan18 protein in chick cranial NCC is unknown. Other cell types release tetraspanins in exosomes, a type of extracellular vesicle, and exosomes have known roles in the induction of EMT as well as promoting invasiveness and motility in cancer cells. It is unknown whether NCC release exosomes, and whether signaling through exosomes regulates NCC EMT. The aim of this project is to determine whether NCC release exosomes and the role of these exosomes in cranial NCC EMT. In order to identify NCC-derived exosomes, chick cranial NCC primary cultures were fixed and stained with the exosomal marker Hsc70 or live imaged using Bodipy Ceramide-TR (BC-TR). NCC expressed Hsc70 throughout the cytoplasm and in live imaging, movement of small, BC-TR labelled vesicular bodies suggests the presence of exosomes. Treatment of NCC cultures with 5 µM or 2.5 µM GW4869, a small molecular inhibitor of exosome biogenesis, resulted in differences in cell shape and migration distance between the treated and DMSO cultures. Together these data suggest that NCC release exosomes, and that exosomes are necessary for NCC migration. Future work will further characterize NCC-derived exosomes and their mode of signaling to define this previously unexplored method of NCC cell communication.

Intermediate Filaments

P641/B656

Identification of a Critical Phosphorylation Site That Regulates the Assembly of Glial Fibrillary Acidic Protein.

S. Delic[1,2], R. Battaglia[1], R. Quinlan[2], N. Snider[1]; [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Durham University, Durham, UNITED KINGDOM.

Intermediate filament (IF) proteins form a major component of the cytoskeleton. There are >70 different human IF proteins, expressed in a cell type-specific pattern. GFAP is the major IF protein of mature astrocytes, important for providing structural support, regulating cell migration, and progression through mitosis. Naturally-occurring missense mutations compromise filament assembly and promote GFAP aggregation, impairing cellular function. Presently it is unclear how these mutations promote defective GFAP proteostasis. Our hypothesis is that naturally-occurring mutations interfere with GFAP filament assembly by disrupting critical post-translational modifications (PTMs). We used a computational approach to map known mutation sites on human GFAP in relationship to PTM sites that have been identified via proteomic studies, and curated by the PhosphoSite database. In parallel, we

performed mass spectrometry phospho-mapping analysis on GFAP extracted from post-mortem brain tissue of human subjects expressing either wild-type (WT) GFAP, or one of the following mutations: N77S, R79C, R239C, R239H, E373K, and D395Y. Based on the results of these analyses, we generated point mutants of GFAP designed to interfere with a key phosphorylation site, and analyzed their assembly properties in transfected cells via immunofluorescence analysis and in *vitro* via transmission electron microscopy (TEM). Our computational analysis of reported PTM sites on GFAP revealed that, in general, the modified residues fall outside of known mutation "hot spots." Specifically, we observed that phosphorylation sites were enriched in the N-terminal 'head' domain of GFAP (spanning residues 1-72), while the majority of GFAP mutations occur within the coiled-coil 'rod' domain (spanning residues 73-377) and C-terminal 'tail' domain (spanning residues 378-432). Furthermore, our mass spectrometry phospho-proteomic analysis revealed that phosphorylation of Serine-13 was highly enriched on human GFAP from subjects carrying missense mutations, but absent in GFAP from subjects expressing WT protein. This result was confirmed by western blot analysis using a phospho-specific antibody. The phospho-deficient mutant S13A formed abnormally short filaments compared to WT GFAP in *vitro* and in transfected cells, while the phospho-mimetic mutant S13D was completely incapable of filament assembly in *vitro,* forming uniform globular particles with an average size of 171nm^2. In transfected cells, S13D was significantly more sensitive to caspase cleavage and became incorporated into large perinuclear aggregates. In conclusion, our results reveal a shared PTM mechanism by which naturally-occurring mutations promote the destabilization of the GFAP intermediate filament network.

P642/B657

Hybrid Approach to Intermediate Filament Structure.

A. V. Lilina[1], P. Vermeire[1], G. Stalmans[1], H. Herrmann[2], **S. V. Strelkov**[1]; [1]KU Leuven, Leuven, BELGIUM, [2]University Hospital Erlangen, Erlangen, GERMANY.

The three-dimensional structure of 10nm wide intermediate filaments (IFs) remains an unresolved problem of structural molecular biology. Functional studies of various IF protein classes are flourishing due to their fundamental importance and scores of disease-related mutations found in IF proteins. Yet the understanding of their 3D structure is clearly lagging behind, aggravated by both intrinsic disorder and heterogeneity. In the past, we have achieved a substantial progress on the atomic structure of the signature central alpha-helical domain of IF proteins which forms a segmented coiled-coil dimer. Our recent crystallographic studies of keratins, vimentin and nuclear lamin a further highlight the dimer-dimer interactions responsible for the filament assembly process. In addition, we use chemical crosslinking coupled to mass-spectrometry analysis to elucidate the arrangement of the dimers in the assembly intermediates and in mature filaments, while cryo-electron microscopy is being exploited to unravel the overall structure of IFs assembled in vitro. Using such a panel of synergistic experimental approaches as well as 3D-modelling we gain substantial new insights into IF structure.

P643/B658

Vimentin Protects the Structural Integrity of the Nucleus and Suppresses Nuclear Damage Caused by Large Deformations.

A. Vahabikashi[1], A. Patteson[2], K. Pogoda[3], S. Adam[1], K. Mandal[4], M. Kittisopikul[1], S. Sivagurunathan[1], A. Goldman[1], R. Goldman[1], P. Janmey[4]; [1]Northwestern University, Chicago, IL, [2]Syracuse University, Syracuse, NY, [3]Institute of Nuclear Physics, Krakow, POLAND, [4]University of Pennsylvania, Philadelphia, PA.

The mechanical properties of the cell and its nucleus are important factors in regulating cell migration through confined spaces. Early in migration, cells often initiate expression of vimentin intermediate filaments (VIFs), which extend from the nucleus to cell periphery. However, the role of VIFs in regulating nuclear shape and mechanics during cell motility is unknown. To examine this role, we used wild type (WT) and vimentin knock out (KO) mouse embryo fibroblasts (MEFs) and performed super resolution microscopy, Transwell migration assays, and atomic force microscopy (AFM). Our findings show that loss of VIFs affect nuclear shape and volume, and increases nuclear blebbing, rupture, and DNA damage during migration through constricting spaces. Image analyses revealed that VIFs are juxtaposed to the nuclear surface in WT cells, forming a cage-like meshwork surrounding it. Nuclei in WT MEFs were flatter and elliptical in shape compared to the KO cells that possessed rounder nuclei as determined by sphericity test. Average nuclear volume in KO MEFs was significantly smaller compared to the WT (475±13 vs. 631±23 μm^3, $p<0.0001$). Data from migration assays show that KO MEFs transit more readily through both pores of 3μm (5.5%±1.7% vs. 1.3%±0.6%, $p<0.01$) and 5μm (11.5%±3.8% vs. 2.55%±0.9%, $p<0.01$). The nucleus area was significantly smaller in WT and KO cells that migrated to the bottom of the membrane compared to those on the top (220±20 vs. 280±10 μm^2, $p<0.01$), yet WT and KO MEFs at the bottom had similar nuclear areas ($p>0.3$). Aspect ratio analysis showed that nuclear shape was altered in both cell types after migration ($p<0.01$), and that KO MEFs had significantly elongated nuclei compared to the WT ($p<0.001$). Translocation through the pores increased the fraction of nuclei with blebs in both cell types ($p<0.001$) with KO MEFs exhibiting 35% more nuclei with blebs than the WT ($p=0.03$). Migration through 3μm pores led to 50% increase in DNA damage repair foci in KO MEFs ($p<0.001$) compared to the WT. AFM results showed that WT MEFs were significantly stiffer in perinuclear region compared to the KO (0.46±0.035 vs. 0.33±0.04 kPa, $p<0.02$). Our results establish a new mechanism for the cytoskeletal resistance to nucleus deformation in cell migration in addition to previously demonstrated role for nuclear lamins. Supported by NIH GM P01 GM096971 and T32 CA080621-15.

P644/B659

Vimentin Intermediate Filaments Drive Cell Extension Formation and Cell Migration in a Substrate-dependent Manner.

Z. Ostrowska-Podhorodecka, R. Liu, C. A. McCulloch; University of Toronto, Toronto, ON, CANADA.

Cell migration involves adhesion to the extracellular matrix and actin filament reorganization, which result in the formation of specialized membrane extensions. Vimentin (VIM) intermediate filaments are centrally involved in cell migration during embryonic development, wound healing and cancer invasion. The direct interactions of actin filaments with the C-terminal tails of VIM, or indirectly through VIM binding partners, modulate cell adhesion receptors involved in cell migration. We considered that the impact of VIM on cell adhesion plays a crucial role in the formation and stabilization of cell extensions

and cell migration. VIM deletion in mouse embryonic fibroblasts (MEF) impaired cell spreading (two-fold; $p<0.01$), decreased the number and length of cell extensions (by 50% and 30%, respectively; $p<0.01$) and altered the localization of the extension tip marker, myosin 10 (MYO10). We found that VIM is required for MYO10 trafficking to the tip of cell extensions. Deletion of VIM promoted accumulation of MYO10 at the edge of the cell membrane (three-fold more compared to WT cell; $p<0.001$). As VIM evidently affects cell extension formation in a substrate-dependent manner, we quantified the impact of VIM expression on cell adhesion to collagen or fibronectin. VIM deletion increased (by 60%; $p<0.01$) fibronectin-coated bead binding compared with collagen binding. Deletion of VIM increased the abundance of total and activated β1 integrin receptors in cells plated on fibronectin. Finally, a phospho-site screen (VIM S39, S56, and S72) indicated that phosphorylation and spatial reorganization of the vimentin is higher on fibronectin (by 60%; $p<0.01$) than collagen what may determine differences in cell motility. In conclusion, our results demonstrate a central role of VIM in the regulation of cell extension formation and stabilization, which affects cell migration.

Keratin 19 Role in Mcf7 Breast Cancer Cells Morphology and Migration.

S. Alsharif; the Catholic Univesity of America, washigton D.C, DC.

Tumor metastasis is associated with epithelial to mesenchymal transition whereby an epithelial cell loses its polarity, cell to cell attachment, and altered expression of keratin intermediate filament proteins. Keratins regulate the shape and mechanical integrity of epithelial cells. Among keratins, keratin 19 is frequently overexpressed in breast cancer and is associated with poor prognosis. We found that K19 plays a role in maintaining epithelial cell shape and tight cell to cell adhesion in MCF7 breast cancer cells, as K19 depletion leads to elongated cell shape and loose cell to cell adhesion. Moreover, K19 depletion increases the migratory potential of MCF7. At the molecular level, E-cadherin, an actin associated adhesive molecule, was surprisingly found to be overexpressed in K19 depleted cells. However, we found that E-cadherin is less membrane associated and less stable in K19 depleted cells. Our results suggest that K19 promotes destabilization of E-cadherin, decreased cell adhesion and increased cell migration.

Vimentin Intermediate Filaments and F-actin Form Interpenetrating Networks in the Cell Cortex.

H. Wu[1], Y. Shen[1], S. Sivagurunathan[2], M. Weber[3], O. Medalia[3], R. Goldman[2], D. Weitz[1]; [1]John A. Paulson School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, [2]Department of Cell and Developmental Biology, Northwestern University Feinberg School of Medicine, Chicago, IL, [3]Department of Biochemistry, University of Zurich, Zurich, SWITZERLAND.

Vimentin intermediate filaments (VIFs) and F-actin are both filamentous cytoskeletal proteins in the cytoplasm but they are typically understood to have vastly different properties and functions. However, there is some evidence that VIFs are involved in cellular functions commonly attributed to actin, which necessitates a closer look at the interplay between the F-actin and VIF cytoskeletons. Using structured illumination microscopy, we image the cortical region of mouse embryonic fibroblasts (MEFs), where we observe close associations between VIFs and F-actin bundles (stress fibers). Furthermore, cryo-electron tomography (cryo-ET) of stress fiber ultrastructure reveals that VIFs are pervasive throughout the structure, suggesting that a stress fiber is an interpenetrating network (IPN) of F-actin and VIFs.

Although many F-actin structures are facilitated by crosslinking proteins, we show that a mixture of purified actin and vimentin proteins self-assembles in vitro into an IPN without the help of binding proteins. Finally, we study the functional consequences of having composite VIF-actin structures in cells, and find that VIFs can significantly impact actin dynamics. We use traction force microscopy (TFM) to find that VIFs play an important role in cell contractility even though they are not intrinsically a force-generating unit; this contribution is likely due to the integrated structure. In addition, fluorescence recovery after photobleaching (FRAP) measurements reveal that VIFs hinder cytoplasmic G-actin diffusion. From these observations, we infer parallels with double-network hydrogels, which are tougher than either of their component gels. These results indicate that the interplay between VIFs and F-actin is an important aspect of cell mechanics, especially as it relates to the contractile nature of cells. These results demonstrate that VIFs play a broad and essential role in cellular mechanics by influencing both the structure and dynamics of actin. Expression of the N-terminal TRSEEX Domain of Bag-1M Prevents Binding to Intermediate Filaments.

A. Mashukova[1], R. Forteza[2], **P. J. Salas**[2]; [1]Nova Southeastern University, Miami, FL, [2]University of Miami Miller School of Medicine, Miami, FL.

Bag1 (Large, Medium, or Small) isoforms are translated from a single mRNA with multiple start codons. Bag-1L and M share TRSEEX repeats in the N-terminal region, which are not present in Bag-1S. Bag1-L also displays a nuclear localization signal (NLS), responsible for nuclear import, not expressed in Bag1-M. Accordingly, the latter is strictly cytoplasmic. In previous work we demonstrated that Bag-1M binds to intermediate filaments (IF), and blocks IF-bound Hsp70 which participates in PKC refolding. Furthermore, Bag1 upregulation induced by TNF-alpha and IFN-gamma resulted in decreased levels of atypical PKC. We hypothesized that TRSEEX repeats must be involved in binding of Bag1-M to IF. We used two synthetic peptides with only one TRSEEX repeat, or the full Bag1-M N-terminal TRSEEX domain, but without the NLS. Both peptides included a C-terminal antennapedia cell-penetrating peptide, known to be effective in Caco-2 intestinal epithelial cells. In the same cell line, we also expressed the Bag1-M TRSEEX domain or the full Bag1-M ORF using stable lentiviral transduction. Both synthetic peptides and the lentiviral expression of the TRSEEX domain reduced nearly 80% the amount of Bag1-M attached to IF. Interacting partners of the TRSEEX domain were determined by BirA-mediated near neighbors biotinylation. Interactions of the Bag1-M N-terminal domain were observed on IF and in neighboring apical membrane compartments. As expected, expression of the TRSEEX Bag1 domain abrogated the post-translational decrease in aPKC induced by proinflammatory signaling. We conclude that this Bag1 N-terminal domain indeed mediates Bag1-M localization to IF but it is also localizes to intracellular membranes.

Exploring the Intermediate Filament Proteome.

U. Axelsson[1], P. Thul[1], D. Mahdessian[1], C. Gnann[1], R. Schutten[2], J. Fall[1], M. Uhlén[1], E. Lundberg[1]; [1]Science for Life Laboratory / KTH, Stockholm, SWEDEN, [2]Uppsala University, Uppsala, SWEDEN.

Intermediate filaments (IFs) are perhaps the most complex, but least well studied, part of the metazoan cytoskeleton. IFs are known to play important roles in cell structure and mechanical support, adhesion

and migration, polarization, and organelle positioning, but also in cell signaling and cytoskeletal crosstalk. IFs are assembled from a diverse family of proteins, the majority of which are expressed in a cell type specific and/or developmentally regulated manner. Therefore, IFs tend to vary greatly in composition, as well as structure and function, ultimately providing each cell type with a unique cytoskeletal signature. Further diversification is achieved by posttranslational modifications and interactions with IF associated proteins (IFAPs). Mutations in genes encoding IF proteins are involved in a number of human diseases, with highly variable pathology. The Cell Atlas, which is part of the Human Protein Atlas (HPA) open access database, aims at providing high-resolution insights into the spatio-temporal distribution of proteins in human cells. Using antibody-based profiling by immunofluorescence and confocal microscopy, we have identified 191 candidate proteins that localize to IFs, including 150 proteins for which there is no previous experimental evidence for localization to this subcellular compartment in the UniProt database. Some of these are known members of the IF protein family, but the majority represent new potential IFAPs, including 18 uncharacterized proteins. Interestingly, as many as 72 of the proteins that localize to IFs display cell-to-cell variation in protein levels, when assayed by staining intensity. This variation may further reflect the complexity of intermediate filament structure and function, ultimately reflecting highly dynamic and responsive cell populations. In this study, we are presenting an overview of the intermediate filament proteome and aim at further characterizing the observed single cell variability among these proteins. This analysis of the IF proteome can provide a valuable knowledge resource for studies of IF function in human health and disease.

The Role of Septins in Platelet Morphology and Functions.

O. V. Kim[1], E. Mordakhanova[2], O. Vagin[3], M. Alber[4], R. I. Litvinov[1,2], J. W. Weisel[1]; [1]University of Pennsylvania, Philadelphia, PA, [2]Kazan Federal University, Institute of Fundamental Medicine and Biology, Kazan, RUSSIAN FEDERATION, [3]Geffen School of Medicine at UCLA, Department of Physiology, Los an geles, CA, [4]University of California Riverside, Riverside, CA.

Platelets are anucleate blood cells that play a role in hemostasis and thrombosis. Activated platelets change shape due to reorganization of cytoskeleton, consisting mainly of actin, tubulin, spectrin, and filamin. Septins, a family of GTP-binding cytoskeletal proteins, are implicated in division of nucleated cells, but their role in platelets remains unknown. Here, we used a combination of high resolution confocal microscopy, biomechanical and biochemical assays to study the distribution of septins 2 and 9 in resting and activated platelets and to explore how disruption of septin assembly impacts platelet morphology and physiology, including contractility, aggregation, adhesion, and integrity. As detected by immunostaining, in resting platelets septin 2 was concentrated almost exclusively around the cell periphery, forming a ring-like structure, while septin 9 formed small patches throughout the cell volume, often with peripheral localization. In platelets activated by thrombin, septins were also present in filopodia. Incubation of platelets with thrombin for longer times (1 hour) caused significant changes in septin organization, leading to a 2-fold increase of septin staining intensity, which was concurrent with a decrease of platelet size due to fragmentation. Impairment of septin dynamics with forchlorfenuron (FCF) caused dose-dependent alterations in platelet shape and functions. First, incubation of platelets with FCF for 1 hour resulted in a substantial decrease of platelet roundness and solidity parameters that quantify cell shape changes. Second, flow cytometry-based analysis of resting platelets treated with FCF indicated a significant 7- to 10-fold increase of the fraction of platelets expressing phosphatidylserine,

activated integrin αIIbβ3, and P-selectin. In FCF-pretreated platelets activated with thrombin-receptor activating hexapeptide (TRAP-6), expression of both phosphatidylserine and activated αIIbβ3 was significantly suppressed, while P-selectin was overexpressed compared to activated cells untreated with FCF. Third, treatment of platelets with FCF impeded platelet-driven clot contraction kinetics with a 6-fold increase of the lag-time and up to a 3-fold decrease of the extent of contraction. At later stages of platelet activation with thrombin, disruption of septin assembly with FCF resulted in a significant acceleration of platelet fragmentation. Meanwhile, FCF did not alter platelet aggregation kinetics induced by TRAP measured with light transmission aggregometery. Our findings suggest that septins play an important role in platelets by stabilizing their shape and maintaining platelet integrity; septins are also involved in the transmission of contractile forces during blood clot contraction.

Tight Junctions

Calcium Signaling Contributes to Epithelial Tight Junction Remodeling during Cell Shape Changes.

S. Varadarajan, R. E. Stephenson, A. L. Miller; University of Michigan, an n Arbor, MI.

Cell shape changes challenge epithelial cell-cell adhesion and barrier function. In order for an epithelium to serve as an effective barrier, tight junctions must be remodeled during events that cause cell shape changes, such as morphogenetic movements and cytokinesis. Using live imaging in the epithelium of gastrula-stage *Xenopus laevis* embryos, we have shown that junction elongation correlates with local loss of tight junction proteins, resulting in a leaky barrier. These leaks are rapidly repaired by localized, transient activation of RhoA - termed “Rho flares” (Stephenson et al., 2019) - which promote actomyosin-mediated reinforcement of tight junction proteins. However, the mechanism underlying local activation of Rho flares is unknown. Here, we show that a transient increase in intracellular calcium (Ca^{2+}) precedes activation of Rho flares and is localized to the site of Rho flares. Further, our data shows that intracellular Ca^{2+} increase is required for activation of Rho flares and efficient reinforcement of tight junction proteins. Because Rho flares are associated with junction elongation and apical plasma membrane deformation (Stephenson et al., 2019), we propose that a mechanosensitive channel, Piezo1, may be responsible for Ca^{2+} influx at the site of Rho flares. However, the localization of Piezo1 in the *Xenopus* epithelium and its potential function in regulating Ca^{2+} influx during tight junction repair are unknown. We find that Piezo1 is expressed in the gastrula stage *Xenopus* epithelium and localizes to apical cell-cell junctions. Both a broad mechanosensitive channel inhibitor (Gadolinium chloride) and a more specific Piezo1 inhibitor (GsMTx4) attenuate externally-induced Rho flare activation and Ca^{2+} influx. Interestingly, partial knockdown of Piezo1 increases the frequency of barrier leaks, alters Ca^{2+} influx dynamics, and causes abnormally large Rho flares. Together, our results suggest that mechanically-triggered Ca^{2+} influx through Piezo1 mechanosensitive channels may be an important feature of the mechanism by which cells sense and repair transient leaks in barrier function. Claudin-specific Interactions at the Tight Junction Cytoplasmic Plaque.

E. Gamero-Estevez[1], A. K. Ryan[1,2]; [1]McGill University, Montreal, QC, CANADA, [2]Research Institute of the McGill University Health Centre, Montreal, QC, CANADA.

Tight junctions are essential to regulate paracellular transport as well as to coordinate morphogenesis during development. Our lab showed that claudins, the main components of tight junctions, are essential for the proper elevation and fusion of the neural folds during neural tube closure. In fact, the removal of Cldn3, -4 and -8 through treatment with the C-terminal domain of *Clostridium perfringens* enterotoxin (C-CPE) generated open neural tubes and convergent extension defects in 100% of the embryos treated. Claudins are composed of a cytoplasmic tail, two extracellular and four transmembrane domains. They are known to interact with other claudins in the same or apposing cell using the extracellular or transmembrane domains. On the other hand, the cytoplasmic tail has been proposed to interact with different scaffolding proteins and cytoskeleton. However, a direct experiment has not been performed to identify specific interactors for each claudin. In our study, we used the cytoplasmic C-terminal domains from different claudins to identify claudin-specific interaction partners for Cldn1, -3, -4, -8 and -14 from different stages of embryogenesis (mid-neurulation, late neurulation and early organogenesis). We observed different interaction profiles for the individual claudins at the different embryonic stages. We hypothesize that this reflects the claudin-specific functions and dynamic expression patterns during development.

Lights, Camera, Rho Flare Action: Inducing Contractility with Optogenetics.

S. A. Chumki, R. E. Stephenson, A. L. Miller; University of Michigan - an n Arbor, an n Arbor, MI.

Epithelial tissues generate barriers that compartmentalize multicellular organisms, support homeostatic nutrient and water transport, and prevent pathogens from invading the tissue. Epithelial cell-cell junctions, including tight junctions (TJs), which seal the paracellular space between cells, and adherens junctions, which promote cell-cell adhesion, are connected to an apical bundle of F-actin and Myosin II (actomyosin). Cell shape changes driven by dynamic events including cell division, wound healing, and developmental morphogenesis generate tension along junctions, which challenges cell adhesion and barrier function. We have shown that “Rho flares”, short-lived, local accumulations of active Rho, rapidly repair local leaks in barrier function *via* local actomyosin-dependent contraction of the junction[1]. However, the mechanism by which Rho flares are triggered remains unknown. Because Rho flares are preceded by junction elongation and a local loss of TJ proteins, we hypothesize that junction elongation may act as a mechanical trigger that initiates TJ leaks and the Rho flare repair mechanism. In order to test this hypothesis, we have adapted the previously-described TULIP optogenetic system, which locally activates contractility upon light stimulation[2], for use in live *Xenopus laevis* embryos. We have shown that whole-field light stimulation elicits recruitment of a photo-recruitable GEF followed by RhoA activation at cell-cell junctions in *Xenopus* embryos. We also observe cell shape changes (e.g. junction straightening) associated with actomyosin contractility upon whole-field stimulation. We aim to use targeted light stimulation of TULIPs to elongate junctions on demand with high spatiotemporal precision. This system will allow us to test whether junction elongation triggers local TJ leaks and Rho flares and will provide a platform for us to further investigate the mechanism of Rho flare activation. Bicellular and Tricellular Tight Junction Molecules Localize to Midbody and Centrosome during Cytokinesis in Human Endometrial Carcinoma Cell Line.

T. Kojima, 060-8556, T. Konno, T. Kohno, S. Kikuchi, H. Shimada, S. Satohisa, T. Saito; Sapporo Med University Sch Med, Sapporo, JAPAN.

Epithelial integrity and barrier function are maintained during cytokinesis in vertebrate epithelial tissue. The changes in localization and the roles of the tricellular tight junction molecule lipolysis-stimulated lipoprotein receptor (LSR) during cytokinesis are not well known, although new tricellular tight junctions form at the flank of the midbody during cytokinesis. In this study, we investigated the changes in localization and the role of LSR at the midbody and centrosome during cytokinesis using human endometrial carcinoma cell line Sawano, comparing the tricellular tight junction molecule tricellulin, bicellular tight junction molecules occludin, claudin-7, ZO-1 and cingulin and the epithelial polarized related molecules ASPP2, PAR3 and YAP. During cytokinesis induced by treatment with taxol, the epithelial barrier was maintained and the tricellular tight junction molecules LSR and tricellulin were concentrated at the flank of the acetylated tubulin-positive midbody and in γ-tubulin-positive centrosomes with the dynein adaptor Hook2, while the other molecules were also localized there as well. All the molecules disappeared by knockdown using siRNAs. Furthermore, by the knockdown of Hook2, the epithelial barrier was maintained and most of the molecules disappeared from the centrosome. These finding suggest that bicellular and tricellular tight junction molecules may play crucial roles not only for barrier function but also for cytokinesis.

P654/B670

ZO-1 in Epithelial Morphogenesis:a Regulator and Transducer of Mechanical Force.

A. J. Haas, M. S. Balda, K. Matter; UCL, London, UNITED KINGDOM.

Epithelia are cell sheets that separate body compartments by forming barriers. Epithelial morphogenesis is a process that drives development and puts tissues under physical constraints. Adaptations in cell-cell and cell-extracellular matrix (ECM) tension are necessary to maintain barrier function during this process, but the mechanisms balancing these forces are not well understood. The tight junction protein ZO-1 plays a central scaffolding role and tethers the actin cytoskeleton to transmembrane cell-cell adhesion proteins. We hypothesized that ZO-1 plays a central role in the balancing of mechanical forces by transducing cell-cell tension from the neighbouring cells to the cytoskeleton and by spatially regulating actomyosin activity through biochemical signalling. To validate our hypothesis, we used RNAi against ZO-1 in MDCK cells grown on different matrix stiffness to model varying monolayer tension conditions. Using a ZO-1-based FRET tension sensor, we observed that tension at tight junctions in MDCK cells correlated with ECM stiffness. Forces acting on E-cadherin were regulated by ZO-1 in a substrate stiffness-dependant manner. On stiff matrix, ZO-1 knockdown induced a flattened cell morphology with partially disrupted cell-cell junctions and increased tension on E-cadherin. The cell cytoskeleton was also affected: RhoA-GEFs, actomyosin and focal adhesions redistributed, which

correlated with increased F-actin polymerisation and myosin II phosphorylation. On soft substrates, tension decreased in ZO-1-depleted cells and traction force microscopy revealed reduced substrate traction upon ZO-1 depletion, which confirmed the decrease in cytoskeletal tension. On even softer substrates, ZO-1 depletion only led to a reduction in the cells capability to form continuous monolayers and disrupted lumen formation in 3D culture. We then used RNAi to identify ZO-1 transmembrane binding partners that could transduce tension and observed that JAM-A knock-down led unexpectedly to increased tension at tight junctions with no significant impact on adherens junctions. Finally, depletion of ZO-1 also impacted on transcriptional pathways regulated by tight junctions, leading to activation of YAP/TAZ signalling via a biochemical mechanism rather than tension-induced activation. To summarise, we demonstrate that crosstalk between apical and basal adhesion dynamics in epithelia is regulated by ZO-1 in a matrix-stiffness-dependant manner by mechanisms that involve biochemical signalling and transduction of tensile force across ZO-1.

P655/B671

Activation of the Ca^{2+} Sensing Receptor and the PKC/WNK4 Downstream Signaling Cascade Induces Incorporation of ZO-2 to Tight Junctions and Its Separation from 14-3-3.

E. Amaya[1], L. Alarcón[1], D. Martín-Tapia[1], F. Cuellar-Perez[1], M. Cano-Cortina[1], J. Ortega-Olvera[1], B. Cisneros[1], A. Rodriguez[2], G. Gamba[3,4], **L. Gonzalez-Mariscal**[1]; [1]CINVESTAV, Mexico city, MEXICO, [2]Rutgers University, Newark, NJ, [3]UNAM, Mexico city, MEXICO, [4]Instituto Nacional de Ciencias Médicas y Nutrición, México, MEXICO.

Tight junction (TJ) protein ZO-2 displays a diffuse cytoplasmic distribution in cells cultured in low calcium (LC, 1-5 µM). However, if in confluent MDCK cells cultured in LC, the Ca^{2+} sensing receptor (CaSR) is activated with Gd^{3+}, ZO-2 appears at the cell borders. Here we have explored the signaling cascade triggered by the activation of the CaSR that leads to ZO-2 movement from the cytoplasm to the cell borders. CaSR is a G coupled receptor whose signaling through $G\alpha_{q/11}$ leads to activation of PKC. Accordingly, in cells cultured in LC, ZO-2 appears at the cell borders after treatment with DiC8, a permeable analogue of diacylglycerol that stimulates novel and conventional PKCs. Next we observed that treatment of LC cultured cells with bryostatin an stimulator of nPKC δ and ε, or with Gd^{3+} and röttlerin, an inhibitor of nPKC δ, allows the arrival of ZO-2 to the cell borders, thus indicating that activation of nPKCε is sufficient to induce ZO-2 relocation to the cell borders. Since PKC phosphorylates and activates with no lysine kinase-4 (WNK4), which favors TJ formation, we next analyzed the impact of bryostatin or DiC8 treatment on ZO-2 in LC cultured cells, observing with a proximity ligation assay (PLA) and immunoprecipitation assays that ZO-2 phosphorylation at serine residues augmented as well as ZO-2/WNK4 interaction, while inhibition of WNK4 with WNK463 blocked cell appearance at the cell borders induced by Gd^{3+} or DiC8, as well as ZO-2 phosphorylation at serine residues after DiC8 treatment. In addition, we observed that in LC, ZO-2 is protected from degradation by association to 14-3-3 proteins, and that stimulation of CaSR with Gd^{3+} diminishes the cytoplasmic co-localization of the ZO-2/14-3-3 complex. U2 region of ZO-2, and S261 located within a nuclear localization signal, are critical for the interaction with 14-3-3 ζ and σ and for the efficient nuclear importation of ZO-2. In summary, our results reveal the appearance of ZO-2 at the membrane triggered by activation of the CaSR/PKCε/WNK4 signaling pathway and the subsequent the disassembly of the cytoplasmic ZO-2/14-3-3 complex.

P656/B672

Rho Flares Rapidly Repair Local Breaches in Tight Junctions.

R. E. Stephenson, A. L. Miller; University of Michigan, an n Arbor, MI.

An important function of epithelial tissues is to create biological barriers, thereby generating an internal environment distinct from the external environment of an organ or organism. Tight junctions play a key role in regulating the strength and selectivity of this barrier. However, many epithelial tissues are routinely subjected to intrinsically and extrinsically generated mechanical forces, such as those resulting from morphogenesis, cell division and extrusion, or normal organ function (e.g., bladder filling). To determine the degree to which these events challenge barrier integrity, we combined high spatiotemporal imaging in the *Xenopus laevis* embryo with ZnUMBA (Zinc-based Ultrasensitive Microscopic Barrier Assay), an assay that allows us to monitor subcellular changes in barrier function in real time. Using this approach, we found that local, transient breaches of tight junctions are caused by events that elongate junctions, such as cell division. These localized leaks are followed by Rho flares, sites of locally activated Rho GTPase, which repair the leak and locally increase tight junction and adherens junction proteins, such as ZO-1, occludin, and E-cadherin. We find that actomyosin-mediated junction contraction is critical for efficient leak repair and reinforcement of the tight junction. Rapid repair of the tight junction following cell shape change allows epithelial tissues to tolerate changes to cell shape with minimal impact on barrier integrity. Ongoing work focuses on the role of specific components of adherens junctions, tight junctions, and the cytoskeleton in facilitating efficient barrier restoration.

P657/B673

Nanoparticles That Interact with Beta 1 Integrin Promote Junctional Rearrangement at a Distance Due to Cytoskeletal Rearrangement Depending on Their Geometry.

R. J. Peterson[1], C. R. Zamecnik[2], T. A. Desai[2], M. Koval[1]; [1]Emory University, Atlanta, GA, [2]University of California San Francisco, San Francisco, CA.

Epithelia form selective barriers that compartmentalize organs which allows for specialized physiologic function. Epithelial barrier permeability has two regulated components, the transcellular path mediated by transcytosis, and the paracellular path regulated by tight junctions (TJs). We previously determined that contact between the apical plasma membrane and nanostructured films (NSFs) increases the permeability of epithelial cells to large macromolecules, such as Alexa-594 Fab, through both the transcellular and paracellular pathways. Several lines of evidence identified a role for apically localized beta 1 integrin in the ability of NSFs to increase substrate permeability. However, a drawback to using NSFs is that they act by engaging large, heterogeneous patches of the apical plasma membrane making it difficult to precisely define molecular mechanisms linking specific surface proteins to changes in epithelial barrier function. Thus, to specifically investigate whether beta 1 integrin is directly involved in increased barrier permeability, we developed a nanowire system consisting of anti-beta 1 integrin antibodies conjugated to functionalized polycaprolactone nanowires. These anti-integrin nanowires serve as a platform to specifically cluster apically localized beta 1 integrin to determine whether integrin stimulation has the capacity to regulate epithelial barrier function. Treatment of epithelial monolayers with anti-integrin nanowires significantly decreased the transepithelial resistance of the monolayer and increased the rate of transepithelial flux of Alexa-594 Fab across monolayers. These functional effects were associated with nanowire-induced changes in the localization of the TJ scaffolding protein zonula

occludens-1 (ZO-1) as well as rearrangement of the actin cytoskeleton from stress fibers into a more cortical pattern of organization. Recently we have observed that the majority of these changes in ZO-1 localization do not occur in regions where the nanowires are in direct contact with ZO-1, but rather the anti-integrin nanowires induced these changes at a distance. Additionally, we have observed that the shape and size of the antibody conjugated nanoparticles plays a role in the severity of the barrier function response. Longer nanowires (15um x 200nm) have a more pronounced effect on barrier permeability, while shorter nanowires (5um x 200nm) have a more pronounced effect on ZO-1 localization. Anti-integrin microspheres (2um) have a moderate effect on both permeability and TJ structure. These data show that clustering apical beta 1 integrin does not have a local effect on TJ barrier structure, and that the regulation of transepithelial permeability via anti-integrin nanoparticles is dependent on nanoparticle geometry.

P658/B674

Probing the Molecular Architecture of Claudin-based Tight Junction Strands.

C. Hempel[1], J. Protze[2], E. Altun[1], B. Riebe[1], A. Piontek[2], I. M. Lee[1], A. From m[1], T. Saleh[1], D. Günzel[1], G. Krause[2], J. Piontek[1]; [1]Charité – Universitätsmedizin Berlin, Institute of Clinical Physiology, Berlin, GERMANY, [2]Leibniz-Forschungsinstitut für Molekulare Pharmakologie (FMP), Berlin, GERMANY.

Models of molecular architecture of tight junction (TJ) strands and paracellular channels have been proposed. However, they were not fully consistent with experimental and structural data. Here, we analyzed architecture of claudin-based TJ-strands and channels by cellular reconstitution of strands, structure-guided mutagenesis, in *silico* protein docking and oligomer modeling. Prototypic channel- (Cldn10b) and barrier-forming (Cldn3) claudins were analyzed. FRET-assays indicated multistep claudin polymerization, starting with claudin subtype-specific *cis*-oligomerization and extending by *trans*-interaction-mediated *cis*-polymerization. Alternative protomer interfaces were modeled in *silico* and tested by cysteine-mediated crosslinking, confocal- and freeze fracture electron microscopy-based analysis of strand formation. The results indicated antiparallel double row arrangement of protomers in Cldn10b- and Cldn3 strands, similar as suggested previously for Cldn15. Hydrophilic and hydrophobic *cis- and trans*-interfaces containing extracellular segment (ECS) 1 and ECS2 residues were defined. Cldn10b and -3 are indicated to share this polymerization mechanism. However, electrostatic repulsion (Cldn10b) or attraction (Cldn3) in the paracellular center of tetramers leads to pore- or barrier formation, respectively. Together, the study provides improvement of the molecular and mechanistic understanding of paracellular permeability regulation and its pathogenic alteration.

P659/B675

The Role of ATPIF1 Protein for Skin Barrier Function.

C. Park, **J. Seo**, H. Lee, Y. Nam, J. Kang, H. Jung, Y. Lee, J. Chung; CHA university, Gyeonggi-do, KOREA, REPUBLIC OF.

The skin barrier is essential to maintain homeostasis and prevents water loss from the skin inside. The tight junction transmembrane proteins are known as important regulators on skin barrier function. A number of tight junction proteins including claudins, occludins and junctional adhesion molecules (JAMs) have been shown to form a barrier in the epidermal keratinocytes, the predominant cell type in the skin epidermis. In the present study, we identified new role of ATPase inhibitory factor 1 (IF1), an F1F0-ATP synthase inhibitor protein in improving skin barrier function. IF1 is a physiological inhibitor for

mitochondrial F1F0-ATP synthase with its binding activity. F1F0-ATP synthase is mainly located within the mitochondrial matrix; however, its F1 catalytic subunit β-F1-ATPase may also be localized on the plasma membrane of keratinocytes. So it is possible that cell surface F1-ATPase, namely ecto-F1-ATPase is involved in a different biological function and exogenous IF1 administration can act as a ligand for F1-ATPase to induce specific cellular responses. We observed that human epidermal keratinocytes (HEKs) exposed to recombinant IF1 protein underwent concentration-dependent cell proliferation as analyzed by WST-1 cell proliferation assay. The expression of tight junction proteins such as claudin-1 and JAM-A was also increased by IF1 protein treatment in a concentration-dependent manner. IF1 protein treatment significantly increased the transepithelial electrical resistance (TEER) of keratinocytes, indicating intact barrier function as electrical resistance across a cellular monolayer and prevention of transepidermal water loss. To confirm the cellular integrity, paracellular permeability was measured with in vitro transwell system using 4 kDa FITC-dextran was measured in keratinocytes. IF1 protein treatment decreased keratinocyte cell permeability 60% compared with the control group. Our findings provide new insight into the role of IF1 of the skin barrier formation, and may contribute to a potential therapeutic target for therapy of epidermal barrier defects.

P660/B676

Association of Dynamin-2 with Morphological Changes at Tight Junctions in Lung Alveolar Epithelial Cells.

K. S. Lynn, B. Schlingmann, R. M. Cornely, S. A. Molina, M. Koval; Emory University, Atlanta, GA.

Acute respiratory distress syndrome (ARDS) is a severe and oftentimes fatal lung disease characterized by widespread fluid flooding of the lungs. Maintenance of fluid balance in the lung airspace is critical for survival of ARDS. Chronic alcohol abuse is associated with impaired fluid balance in the lungs and magnifies the severity and risk of ARDS. Our lab is currently investigating the molecular mechanisms of chronic alcohol abuse and the increased risk of ARDS with a particular interest in the effects on tight junctions. Previously we determined that an increase in tight junction protein claudin-5 was associated with chronic alcohol ingestion. This increased expression of claudin-5 was necessary and sufficient to reduce barrier function and induced the molecular rearrangement of tight junction proteins to form spike-like protrusions (referenced as tight junction spikes (TJ spikes)) perpendicular to the linear junction. Upon closer inspection of the TJ spike structures, we observed vesicle budding and fusion at the TJ spikes, suggesting that these structures could be areas of active junction remodeling, known to be facilitated by endocytosis of junction proteins. Upon treatment with endocytosis inhibitor Dynasore, which targets the actin-binding protein dynamin, we observed a decrease in the number of TJ spikes, suggesting a role for dynamin in TJ spike formation. We determined by immunoblot that dynamin-2 is the dominant isoform in primary rat lung alveolar type I epithelial cells and observed dynamin-2 localized to tight junctions and TJ spikes by immunofluorescence. Using super-resolution immunofluorescence microscopy (Stimulated Emission Depletion (STED)) to further investigate the localization of tight junction proteins within TJ spikes, we observed irregular distribution of ZO-1 compared to claudin-18 within the TJ spikes. We further observed several TJ spike intermediate structures that we hypothesize to be maturing TJ spikes. We are currently using live-cell microscopy and super-resolution microscopy to further characterize TJ spikes and their role in epithelial barrier function and maintenance. Our long-term goal is to identify novel therapeutic targets to rescue barrier function by restoring normal tight junction morphology.

Cadherins and Cell-Cell Interactions

P661/B677

Resolving the Mechanism of Adhesion Mediated by a Non-clustered Delta-1 Protocadherin.

D. Modak, M. Sotomayor; the Ohio State University, Columbus, OH.

Cadherins form a large family of calcium-dependent cell adhesion proteins involved in cell differentiation, tissue morphogenesis and neuronal connectivity. Being membrane proteins, they have an extracellular, a transmembrane and a cytoplasmic domain. Non-clustered delta-1 protocadherins are a subgroup of cadherins with seven extracellular cadherin (EC) repeats, a single-pass transmembrane domain, and cytoplasmic domains distinct from classical cadherins. These proteins mediate homophilic adhesion and have been implicated in various diseases, including asthma, autism, epilepsy and cancer. However, how delta-1 protocadherins use their extracellular domain to mediate adhesion is unknown. Here we present the first X-ray crystal structures of the extracellular domain of a delta-1 protocadherin member, Protocadherin-1 (PCDH1), expressed mainly in the airway epithelium, skin keratinocytes, and lungs. PCDH1 is involved in asthma and hantavirus related pulmonary syndrome infection. The structures revealed binding modes that involve antiparallel as well as parallel overlap of multiple EC repeats. Mutagenesis, binding assays and other biochemical experiments tested the modes of adhesion as predicted from these structures. Overall, our studies reveal the molecular mechanisms of adhesion mediated by PCDH1 and shed light on its role in maintaining epithelial integrity, the loss of which causes asthma. Given the sequence similarity among delta-1 protocadherins, these mechanisms of adhesion are likely the mechanism of adhesion for all of them. Further, the structure of PCDH1 EC1, which is used for infection by Hantavirus will open up new avenues of drug design against the disease.

P662/B678

Resolving Species-dependent Heterophilic and Homophilic Cadherin Interactions in Intestinal Epithelium Intermicrovillar Links.

M. Gray, Z. Johnson, **D. Modak**, M. Sotomayor; the Ohio State University, Columbus, OH.

Enterocytes are specialized epithelial cells lining the luminal surface of the small intestine involved in nutrient absorption, processing and host defense. Terminally differentiated enterocytes have densely packed arrays of microvilli known as the brush border. The microvilli are arranged in a hexagonal pattern that is maintained by intermicrovillar links formed by two non-classical members of the cadherin superfamily of calcium-dependent cell adhesion proteins: Protocadherin-24 (PCDH24) and the mucin protocadherin (CDHR5). Cadherins typically have an extracellular domain with a variable number of extracellular cadherin (EC) repeats followed by a transmembrane and a cytoplasmic domain. PCDH24 has 10 EC repeats and a membrane adjacent domain while CDHR5 has 4 EC repeats and membrane adjacent mucin-like domains. Intermicrovillar links are formed by the heterophilic and homophilic interactions of PCDH24 and CDHR5. Here we present binding assays that identify the PCDH24 and CDHR5 EC repeats involved in both heterophilic and homophilic adhesion for human and mouse proteins. We also present the first X-ray crystal structures of the PCDH24 and CDHR5 tips and analyze species-specific differences in the mode of adhesion of these proteins. Structures together with binding assays and mutagenesis are shedding light on how brush border assembly, key to nutrient absorption, is driven by cadherins.

P663/B679

Role of Jak/Stat Signaling during Neural Crest Migration.

E. Kunttas, M. Bronner; California Institute of Technology, Pasadena, CA.

Many of the molecular mechanisms acting during early embryogenesis are reiterated during tumor initiation, progression and metastasis. The JAK/STAT pathway has a well established role in cancer cell invasion and collective cell migration in the Drosophila. Here, we show that JAK/STAT signaling also plays a role in neural crest migration during vertebrate development. Loss and gain of STAT3 function leads to defects in neural crest delamination and migration, at least partially due to dysregulation of key EMT transcription factors like Ets1 as well as the cell adhesion molecule E-cadherin. Our findings reveal a novel role for JAK/STAT signaling pathway during neural crest migration and suggest that is plays an evolutionarily conserved role in collective cell migration.

P664/B680

Kinetic Nucleation-dependent E-cadherin Clustering Regulates Alpha-Catenin Conformational Activation.

K. H. Biswas; Hamad Bin Khalifa University, Doha, QATAR.

E-cadherin-based cell-cell adhesion (E-cadherin adhesion) is essential for organogenesis and maintenance of the epithelial tissue, and a loss of cell- cell adhesion has been suggested to contribute to cancer development. In addition to performing its adhesive function through the extracellular domain-mediated homotypic interaction, E-cadherin adhesion enables cells to sense mechanical tension in the tissue through the adaptor protein, alpha-catenin. This has been proposed to be mediated through, in part, a conformational change in alpha-catenin upon increase in the actomyosin tension on E-cadherin adhesion resulting in the availability of cryptic binding sites in alpha-catenin leading to an enhancement in its interaction with vinculin, an adaptor protein that is homologous to alpha-catenin, and the actin cytoskeleton. Reconstitution of E-cadherin adhesion in a hybrid format wherein a live cell interacts with a synthetic, supported lipid bilayer functionalized with the extracellular domain of E-cadherin showed that cells utilize filopodia to cluster E-cadherin. Importantly, E-cadherin clustering requires a reduced diffusive mobility of the protein on the membrane indicating the presence of a step of kinetic nucleation in the process. Further, experiments with nanopatterned supported lipid bilayer substrates revealed that the size of E-cadherin clusters regulate the conformational activation of alpha-catenin. Once activated, however, alpha-catenin is sustained in the active conformation even when actomyosin tension in the cell is reduced pharmacologically. Thus, membrane diffusion-regulated E-cadherin clustering impacts alpha-catenin conformational activation and mechanical signaling.

P665/B681

Cell Proliferation Controls Cell Shape Remodeling in Epithelia.

J. Devany[1], D. Sussman[2], L. Manning[2], M. Gardel[1]; [1]University of Chicago, Chicago, IL, [2]Syracuse University, Syracuse, NY.

Epithelia have distinct cellular architectures, which are maintained despite externally applied forces, wounding, and cell division or death. In turn, cell shape is thought to affect tissue function by controlling cell differentiation, and motility. Here we investigate cell shape changes in a model epithelial monolayer of MDCK cells. After the onset of confluence, we find that cells continue to divide and change shape

over time, eventually reaching a similar final state characterized by arrested dynamics and more hexagonal cell shapes. On substrates of different stiffness, monolayers form with different cell density, but have a similar relationship between cell shape and dynamics. This suggests that cell shape controls motility in confluent monolayers. We find that inhibiting different cytoskeletal regulators causes monolayers to arrest with elongated cell shapes. Interestingly, across a diverse set of inhibitor conditions, final cell shape is correlated with the rate of cell division. By measuring the shape change of individual cells during monolayer remodeling we demonstrate oriented cell division is insufficient to explain this relationship. We observe similar changes in the cell shape behavior when modifying the effective surface tension in an active vertex model. This suggests that changes in cell shape remodeling result from differences in cell mechanical properties. To understand the mechanism which couples cell mechanics and proliferation in monolayers we perturb several molecular pathways which regulate both the cytoskeleton and the cell cycle. Our results reveal an important connection between cell proliferation and cell mechanics which controls cell shape remodeling in epithelia.

P666/B682

Junctional Localization of Septin 2 Is Crucial for Integrity of Junctional Molecules in Endothelial Monolayer.

J. Kim, J. A. Cooper; Washington University, St Louis, MO.

It was previously demonstrated that Septin 2 is required to regulate barrier function of microvascular endothelial monolayer. Loss of Septin 2 protein altered organization of vascular endothelial (VE)-Cadherin, adherens junctional molecule as well as dynamic membrane protrusion at the cell-cell contact sites. On top of that, we recently found that localization of Septin 2 at the junctions is necessary to control integrity of junctional molecules. TNF-alpha treatment with microvascular endothelial cells sequestered Septin 2 to the cytoplasm from the junctions without the effect of protein level. Interestingly, TNF-alpha treatment revealed the same effect with loss of Septin 2 on various junctional molecules of adherens junctions (AJs) and tight junctions (TJs). Immunofluorescent staining analysis showed dramatic loss of integrity of AJs and TJs at the junctions. Next, in order to investigate necessity of junctional localization of Septin 2 we performed mutations on amino acid residues in polybasic motif of Septin 2 suggested to interact with $PIP_{2\ in}$ plasma membrane. Of note, overexpression of PIP_2binding mutants of Septin 2 showed accumulation of Septin 2 in the cytoplasm with decrease in junctional localization in microvascular endothelial cells.

P667/B683

Inside-out Regulation of Cadherin Adhesion.

R. Koirala[1,2], A. Priest[1,2], M. Gloerich[3], S. Yamada[1], S. Sivasankar[1]; [1]Department of Biomedical Engineering, University of California, Davis, CA, [2]Department of Physics and Astronomy, Iowa State University, Ames, IA, [3]Center for Molecular Medicine, University Medical Center, Utrecht, NETHERLANDS.

During morphogenesis and wound healing, cellular migration and rearrangements rely on tightly regulated changes in E-cadherin (Ecad) adhesion. Previous studies, carried out in a cell free context, show that Ecad ectodomains bind in two different conformations, strand-swap dimers and X-dimers, which have different adhesive properties. However, the molecular mechanism by which Ecad conformation and adhesion is regulated on cell surface is not understood. To address this critical gap,

we used live cell Atomic Force Microscopy (AFM) to correlate the structure and adhesion of Ecad ectodomains to their cytoskeletal linked states in Madin-Darby Canine Kidney (MDCK) cells engineered with different knockout/mutant versions of α-catenin and vinculin. Our results show that in parental MDCK cells, only a third of non-junctional Ecads are robustly bound to the actin cytoskeleton; the remaining Ecads only transiently associate with the cortical actin. Robust linkage of Ecad to the cytoskeleton requires both α-catenin and vinculin. Strikingly, we show that ectodomains of cytoskeleton bound Ecad adopt a strand-swap dimer conformation while disrupting cytoskeletal linkage traps Ecads in X-dimer conformation. Our data directly demonstrates that changes in Ecad ectodomain structure and adhesion are regulated from the inside-out, by Ecad linkage to the actin cytoskeleton.

P668/B684

Endothelial Junctional Tunnels Are Crucial for Leukocyte Extravasation.

B. Van Steen, J. D. van Buul; Sanquin Research, Amsterdam, NETHERLANDS.

Inflammation is characterized by migrating leukocytes that extravasate from the circulation across the vascular endothelium into inflamed tissue. This is a carefully orchestrated dialogue of adhesion and signaling between leukocytes and endothelial cells. The process is tightly regulated to prevent excessive leukocyte extravasation and vascular leakage. In our study, we demonstrate the role of previously understudied structures at the endothelial level and their role in extravasation using a multitude of advanced imaging techniques (AFM, SEM, TEM, CLSM, and SIM). Using these techniques, we show that endothelial cell junctions are overlapping instead of connecting. To allow for better study of this process we adopted and developed an advanced microfluidic vessel-on-a-chip approach to grow vessels resembling postcapillary venules. These functional vessels are created in a modular system allowing versatility in matrix substance, stiffness, lumen size and cell type(s). We show that this overlapping structure exists in *vitro*, in our vessel on a chip and in *vivo*. Using mosaic expression of specialized membrane-targeting fluorescent constructs, we were able to demonstrate that these overlapping structures play a crucial role in neutrophil extravasation by the formation of tunnels that help neutrophils to crawl through during diapedesis. This work challenges the extravasation dogma stating that endothelial cells would transiently disconnect to allow leukocytes to pass.

P669/B685

Formation of Intercellular Nanotubes Via Helical Deformation.

M. Chang, **G. Bu, 37673**, O. Lee, J. Oh, J. Jeon, J. Lee; POSTECH, Pohang, KOREA, REPUBLIC OF.

Extensive studies on intercellular nanotubes (INT) that physically connect cells have revealed their biological significances as a new pathway for the distant transport of cytoplasmic components, viruses, or pathogenic substances between cells. However, it remains unknown how such a fine structure is formed and sustained robust over long distance for several hours. Using real-time optical imaging in various epithelial cells, we visualized that random contact of filopodia protruding from two different cells forms filopodial bridges (FBs) via cadherin-cadherin interactions and one of the filopodia is ultimately released from the other filopodium, which result in a single long filopodium bridge connecting two cells (INT). Interestingly, super-resolution microscopy revealed a fine helical structure of FBs, which is driven by rotational motions of filopodia due to the twist of actin filaments inside filopodia by myosin-V. Mechanical studies and computer-aided simulation strongly suggest that the transition of FB into INT is likely that accumulated torsional energy in FBs with the helical deformation breaks

cadherin-cadherin interactions between two filopodia and the actin retrograde flow of the released filopodium leaves a single bridge attached to a paired cell. The single bride is strongly supported by cadherin-cadherin clusters at the junction between the end of the bridge and the cell, which is likely a synapse. This study sheds light on the formation mechanism of filopodial bridge-based intercellular nanotubes for long-distance communication between cells.

P670/B686

Expression Profile of Type I and Type II Classical Cadherins during Neuronal Nuclei Formation in the Developing Mouse Subpallium.

J. Polanco, F. Reyes-Vigil, S. D. Weisberg, **J. L. Bruses**; Mercy College, Dobbs Ferry, NY.

The Differential Cell Adhesion Hypothesis of tissue separation states that cell sorting results from differences in intercellular adhesiveness determined by cell adhesion molecules (CAMs) expressed on the cell surface. Type I and type II classical cadherins comprise a group of CAMs that regulate cell sorting by maximizing adhesive strength mediated by homo and heterotypic cadherin binding. Factors that affect the ability of cadherins to regulate cell sorting include the affinity of cadherin binding and their expression levels. This study examines the expression of cadherins type I (CDH1, CDH2, CDH3, CDH4, and CDH15), type II (CDH5, CDH6, CDH7, CDH8, CDH9, CDH10, CDH11, CDH12, CDH18, CDH19, CDH20, CDH22 and CDH24), and the CELSR CDH13 during nuclei formation in the developing mouse subpallium. Cadherin's mRNA expression values were obtained from in *situ* hybridization experiments carried out at the Allen Brain Institute and available at the Allen Developing Mouse Brain Atlas (DMBA). Expression values for each structure were calculated using the Structure Unionizer module and expression energy values ((sum of expressing pixel intensity / sum of expressing pixels) * (sum of expressing pixels / sum of all pixels)) for each structure were analyzed at embryonic (E) 13.5, E15.5, postnatal (P) 28 and P56. At P56, all type I and type II cadherins are detected in the subpallium; however, only CDH2, 8, 11 and 13 show high expression values (between 1 and 16) throughout the subpallium, while CDH5, 6, 9, 10, 12, 18, 20 and 24 show expression values above 1 in only one to three substructures, and CDH1, 3, 4 and 7 show very low expression (expression values for CDH15, 19 and 22 are not available at the DMBA). Expression values at the ontological structure level 8 (which includes twelves substructures) show a progressive increase in expression of CDH2, 8, 11, and 13 throughout development with regional differences in cadherin type and expression level. CDH5, 6, 9, 10, 12, 18, 20 and 24 show variable expression patterns at different stages. The Pearson's correlation coefficient calculated at each developmental stage between cadherins with the highest expression values (CDH2, 8, 11 and 13) show that expression of CDH2 and 13 is significantly correlated at E13.5 ($r = 0.529$), P28 ($r = 0.689$) and P56 ($r = 0.616$), expression of CDH11 and 13 is correlated at E13.5 ($r = 0.569$), while CDH8 and 13 expression is correlated at P28 ($r=0.689$). This analysis shows that cadherin type and expression level are heterogenous among cell pools within the subpallium. This suggest that groups of cells within the subpallial mass have distinct and dynamic patterns of type I and II cadherin expression that may provide an identity that contributes to the segregation of cells from a parental cell group and their aggregation into distinct nuclei.

P671/B687

αT-catenin Intramolecular Interactions Regulate Vinculin Binding.

J. A. Heier[1], S. Pokutta[2], W. I. Weis[2], A. V. Kwiatkowski[1]; [1]University of Pittsburgh School of Medicine, Pittsburgh, PA, [2]Stanford University School of Medicine, Stanford, CA.

Cardiomyocyte contractions place unique physical and regulatory demands on the protein complexes that join these cells. Cardiomyocytes are connected by intercalated discs (ICDs), specialized junctions that mechanically and electrically couple cells. Mechanical linkage at the ICD is accomplished through the adherens junction (AJ) and desmosome that connect to the actin and intermediate filament cytoskeletons, respectively. The core component of the AJ is the cadherin-catenin complex, and α-catenin serves as the primary link between the AJ and actin. Two α-catenins are expressed in the mammalian heart, αE(Epithelial)-catenin and αT(Testes)-catenin. Tension regulates αE-catenin conformation: actomyosin-generated force stretches the middle(M)-region to relieve autoinhibition and reveal a binding site for the actin-binding protein vinculin. In contrast, little is known about the molecular properties of αT-catenin. Here we describe the biochemical properties of αT-catenin and how intramolecular interactions regulate vinculin binding. Isothermal titration calorimetry (ITC) showed that αT-catenin binds the β-catenin/N-cadherin complex with a similar affinity (low nanomolar) to that of αE-catenin indicating a similar association with the AJ. Limited proteolysis revealed that the αT-catenin M-region adopts a more open conformation than αE-catenin. Consistent with these results, ITC revealed that the αT-catenin M-region binds the vinculin N-terminus with low nanomolar affinity, indicating that the αT-catenin M-region is not autoinhibited and distinct from αE-catenin. However, the αT-catenin head domain binds vinculin 1000-fold more weakly (low micromolar affinity), indicating that the N-terminus regulates M-region binding to vinculin. Notably, β-catenin binding to the αT-catenin head domain does not affect vinculin binding. Together, our results indicate that the αT-catenin N-terminus is required to maintain M-region autoinhibition and modulate vinculin binding. We postulate that the unique molecular properties of αT-catenin regulate ligand binding to meet the demands of intercellular adhesion in cardiomyocytes.

P672/B688

Epithelial Cells Act as a Regional Checkpoint for Immune Cell Organization.

S. Park, C. Martone, V. Greco; Yale University, New Haven, CT.

Skin protects our body against the outer environment, and its ability to repair upon injury is directly connected to both disease and survival. Despite recent advances in our understanding of skin homeostasis, it is still unclear how stem cells interact with their niche to sustain this process in a live mammal. The critical barrier to addressing these fundamental questions lies in the inability to simultaneously follow behaviors of different cell types and to define their functional interactions in *vivo*. Skin epidermis is an ideal system because of its accessibility and well-characterized epithelial stem cells and coexisting epidermal immune cells. In the epidermis, epithelial stem cells are closely intermingled with two resident immune cell populations: Dendritic epidermal T cells (DETCs) and Langerhans cells (LCs). Intravital imaging platform with multiphoton microscope allows us to dissect the coordination and functional significance of distinct cell activities, populations and interactions during homeostasis in live mice. In addition to immune surveillance, our data show that both immune populations can perceive and respond to the changes of their neighbors. Epidermal immune cells actively retain spatial organization within their own population while neighboring epithelial stem cells continuously divide and

differentiate. Furthermore, skin epithelial stem cells act as regional checkpoints for the organization and number of epidermal immune populations, but not vice versa. This study reveals new principles of immune organization within the epidermis and elucidates dynamic epithelial-immune interactions that are in place to maintain homeostasis of the epidermis.

P673/B689

RhoA mediates epithelial cell shape changes via mechanosensitive endocytosis.

K. Cavanaugh[1,2], M. Staddon[3], E. Munro[1,4], S. Banerjee[3], M. Gardel[4,5]; [1]Department of Molecular Genetics and Cell Biology, University of Chicago, Chicago, IL, [2]Committee on Development, Regeneration and Stem Cell Biology, University of Chicago, Chicago, IL, [3]Department of Physics and Astronomy, and Institute for the Physics of Living Systems, University College London, London, UNITED KINGDOM, [4]Institute for Biophysical Dynamics, University of Chicago, Chicago, IL, [5]James Franck Institute, and Department of Physics, University of Chicago, Chicago, IL.

RhoA mediates epithelial cell shape changes via mechanosensitive endocytosis Kate E. Cavanaugh[1,2], Michael F. Staddon[3], Ed Munro[1,4], Shiladitya Banerjee[3], Margaret L. Gardel[4, 5 1] Department of Molecular Genetics and Cell Biology, University of Chicago, Chicago, IL 60637, USA, [2]Committee on Development, Regeneration and Stem Cell Biology, University of Chicago, Chicago, IL 60637, USA, [3]Department of Physics and Astronomy, and Institute for the Physics of Living Systems, University College London, London WC1E 6BT, United Kingdom, [4]Institute for Biophysical Dynamics, University of Chicago, Chicago 60637 IL, USA, [5]James Franck Institute, and Department of Physics, University of Chicago, Chicago 60637 IL, USA. Abstract: Epithelial remodeling involves ratcheting behavior whereby periodic contractility produces transient changes in cell-cell contact lengths, which stabilize to produce lasting morphogenetic changes. Pulsatile RhoA activity is thought to underlie many morphogenetic ratchets, but how RhoA governs transient changes in junction length, and how these changes are rectified to produce irreversible deformation, remains poorly understood. Here, we use optogenetics to characterize responses to pulsatile RhoA in model epithelium. Short RhoA pulses drive reversible junction contractions, while longer pulses produce irreversible junction length changes that saturate with prolonged pulse durations. Using an enhanced vertex model, we show that this is explained by two effects: thresholded tension remodeling and continuous strain relaxation. Our model predicts that structuring RhoA into multiple pulses overcomes the saturation of contractility and we confirm this experimentally. Junction remodeling also requires formin-mediated E-cadherin clustering and dynamin-dependent endocytosis. Thus, irreversible junction deformations are regulated by RhoA-mediated contractility, membrane trafficking, and adhesion receptor remodeling.

P674/B690

PI3K Regulates Adhesions in Parietal Endoderm Migration.

B. Griffith, J. Mulrooney; Central Connecticut State University, NEW BRITAIN, CT.

Parietal endoderm outgrowths from F9-derived Embryoid Bodies (EB) are a well-established model system for the in *vitro* study of morphological and molecular events involved in early embryonic yolk sac development including migration. Migration of parietal endoderm mimics a combination of collective sheet migration and contact inhibition of locomotion in an oriented and directed fashion away from the embryoid body. Data suggest that these transient cell to cell interactions are comprised of classical cadherin family adhesion proteins typical of adherens junctions, while cell-ECM interactions are

mediated by typical integrin-containing focal adhesions. Recently, our laboratory has begun to investigate the role of Phosphatidylinositol 3-Kinase (PI3K) signaling in parietal endoderm migration. Inhibition of PI3K using LY294002 phenocopies the effects of siRNA knockdown of E-cadherin. Preliminary data suggest that inhibition of PI3K results in a decrease in E-cadherin containing adhesions at cell-cell boundaries, with a corresponding increase in vinculin containing focal adhesions within the sheet of outgrowth. Vinculin containing focal adhesions on the leading edge of the outgrowth appear to be more numerous and robust. These data suggest a role for PI3K in regulating cell-cell and cell-ECM adhesions during the migration of parietal endoderm Here, we explore the relationship between PI3K and E-cadherin during parietal endoderm migration.

P675/B691

Regulating Interactions between Cell-cell Adhesion Proteins P120-catenin and Plekha7.

L. J. Pence, P. Z. An astasiadis; Mayo Clinic, Jacksonville, FL.

The adherens junction (AJ) is a crucial mediator of cell-cell adhesion and promotes the integrity and stability of epithelial tissue. Additionally, the AJ has important roles in regulating cell signaling, promoting the formation of other junctional complexes, maintaining cytoskeletal integrity, transducing mechanical inputs, and others. The AJ is composed primarily of a core cadherin-catenin complex, including E-cadherin, p120-catenin, β-catenin, and α-catenin. This core cadherin-catenin complex localizes along basolateral contacts and also exhibits a highly organized concentration at the apical membrane. Our lab recently showed the functional relevance of these two distinct cadherin-catenin populations. The apical complex, characterized by the presence of PLEKHA7 (P7), suppresses pro-anchorage independent growth factors, which are driven by the basolateral complex. This regulatory action of the apical complex is dependent upon the presence of P7. P7 recruits components of the RNA-interference pathway, including microRNA processing complex, RNA-induced silencing complex, and a subset of miRNAs and mRNAs, to the apical AJ and thereby mediates localized regulation of translation. The loss of P7 leads to upregulation of pro-anchorage independent growth and pro-tumorigenic proteins, including Snail, Myc and Cyclin D1. It is known that P7 is localized exclusively to the apical AJ through its interaction with p120-catenin. However, nothing is known about how this interaction is regulated. Here, we explore the regulation of the P7-p120-catenin interaction by phosphorylation. We characterize the small binding domain of p120-catenin required for the interaction. Finally, we begin to explore functional effects of this regulation at the AJ and potential implications for normal physiology and disease states.

P676/B692

Investigating the Interactome of the Brush Border Protocadherin Cdhr5 in Transporting Epithelia.

S. Matoo, M. Graves, R. El Sheikh Idris, M. Soo Choi, S. Crawley; University of Toledo, Toledo, OH.

Transporting epithelia of the intestine and kidney mediate solute transport by assembling a brush border (BB): a highly-ordered array of specialized apical microvilli. BB assembly is driven, in part, by a protocadherin-based adhesion complex found at the tips of BB microvilli. Known as the intermicrovillar adhesion complex (IMAC), this protein complex creates physical linkages that connect neighboring microvilli together during BB assembly in order to establish a mature, functional BB. IMAC adhesion is mediated by two calcium-dependent protocadherin molecules: Cadherin Related Family Member 2 (CDHR2; also known as protocadherin-24) and Cadherin Related Family Member 5 (CDHR5; also known

as mucin-like protocadherin). Previous studies revealed that CDHR2 is associated with a cytoplasmic complex comprised of two scaffolding proteins, USH1C and ANKS4B, along with the motor protein Myo7b. To further define the protein composition of the IMAC, we performed a screen to isolate proteins that associate with the cytoplasmic domain of CDHR5 and have identified the PDZ-based scaffold E3KARP as a putative binding partner. Importantly, E3KARP and its closely related homolog EBP50 are highly expressed in the transporting epithelia of the kidney and small intestine, respectively. Here, these scaffolds are thought to associate with Ezrin and numerous transmembrane proteins in order to promote both proper microvillar structure and function. E3KARP/EBP50 are each comprised of two PDZ domains followed by an Ezrin binding domain that terminates with a canonical PDZ-binding motif. Given that EBP50 has been shown to play an essential role in intestinal BB assembly, we focused our attention on characterizing this candidate binding partner using our intestinal models. We observe that CDHR5, EBP50 and Ezrin exhibit partial co-localization within BB microvilli, and that the phosphorylated, active form of Ezrin displays an enrichment towards the tips of BB microvilli, the site of IMAC function. Furthermore, we provide preliminary biochemical data to demonstrate that ternary complex formation between CDHR5-EBP50-Ezrin requires Ezrin to be in an active conformation. Going forward, we will investigate whether sequential activation of Ezrin by $PI(4,5)P_2$ binding and phosphorylation leads to CDHR5-EBP50-Ezrin ternary complex formation. In sum, these results further define the IMAC interactome and reveal a potential mechanism of how CDHR5 may contribute to BB structure through Ezrin.

P677/B693

Investigating the Function and Regulation of the Apical Scaffold an ks4b during Enterocyte Brush Border Assembly.

M. Graves, S. Matoo, R. El Sheikh Idris, Z. Storad, B. Pickles, S. Crawley; the University of Toledo, Toledo, OH.

The transporting epithelia of the intestine interact with their luminal environment by assembling an apical brush border: a densely-packed collection of lumen-oriented microvilli that are highly enriched in nutrient processing enzymes and transport channels. Although essential in gut function, how enterocytes assemble a functional brush border is still poorly understood. Recent studies have shown that a protocadherin-dependent adhesion complex is a key factor in driving brush border assembly. Microvillar organization is mediated by a pair of protocadherins (CDHR2 and CDHR5) that interact in *trans* to create physical linkages between the neighboring microvilli at their distal tips. To permit correct tip targeting and function, these protocadherins require association with a cytoplasmic complex that includes two scaffolding proteins, Harmonin and ANKS4B, and a myosin motor, Myo7b. Altogether, these components are known as the intermicrovillar adhesion complex (IMAC). Here, we provide evidence that ANKS4B acts as the 'primordial' scaffold used to assemble the IMAC within the enterocyte apical domain in a regulated manner. ANKS4B is comprised of an N-terminal ankyrin-repeat domain, a central unstructured region and C-terminal sterile α-motif ending in a PDZ-binding motif. While ANKS4B has been shown function as a scaffold by directly interacting with Myosin-7b and Harmonin, little is known about either its regulation or targeting properties. We show that ANKS4B is the first IMAC component expressed during enterocyte polarization, and that ANKS4B possesses a dedicated BB-targeting domain that promotes apical targeting independent of the other adhesion complex components. Furthermore, we demonstrate that ANKS4B is subject to phosphorylation, and that phosphorylation of the scaffold modulates its functional properties during BB assembly. Together, our

study further defines the role of ANKS4B within the IMAC and sheds light on how dysfunction of ANKS4B results in perturbed BB structure, which may contribute to GI disease.

Cell Death: ROS & ER-Stress

Haploinsufficiency of U17 Small Nucleolar Rnas Reprograms Cellular Metabolism and Regulates Metabolic Stress.

A. Sletten, M. Schwaiger-Haber, S. Zhao, H. Fujiwara, S. Gale, X. Jiang, R. Sidhu, S. Gelman, G. Patti, D. Ory, J. Schaffer; Washington University in St. Louis, St. Louis, MO.

Dyslipidemia and resulting lipotoxicity are common features of metabolic syndrome and type 2 diabetes. Excess lipid causes cell dysfunction and induces cell death through pleiotropic mechanisms that link to oxidative stress. Through a retroviral promoter trap mutagenesis screen, we isolated a cell line that is resistant to lipid-induced cell death and oxidative stress. We show that disruption of the box H/ACA U17 snoRNAs encoded within the small nucleolar hosting gene 3 *(Snhg3*) causes resistance to lipid-induced cell death and general oxidative stress. This protection from metabolic stress results from upregulation of the mammalian target of rapamycin (mTOR) signaling axis and is associated with increased oxidative metabolism. Our findings demonstrate a novel role for the U17 snoRNAs as regulators of cell metabolism and stress response pathways.

P679/B696

MUC5B Expression in IPF is Associated with ER Stress and Impaired Mitochondrial Function.

E. Dobrinskikh, A. Estrella, J. S. Kurche, I. V. Yang, D. A. Schwartz; University of Colorado, Aurora, CO.

Rationale: Idiopathic Pulmonary Fibrosis (IPF) is a chronic progressive lung disease characterized by parenchymal remodeling and heterogeneous fibrosis due to poorly understood mechanisms. The gain-of-function *MUC5B* promoter variant rs35705950 is the strongest risk factor for IPF. MUC5B protein expression is upregulated in bronchoalveolar epithelial cells and honeycomb cysts in patients with IPF. Pulmonary fibrosis develops as a final pathological outcome of impaired wound healing responses to persistent lung injury and is characterized by the excessive extracellular matrix (ECM) deposition in the lungs. It is known that persistent endoplasmic reticulum (ER) stress in alveolar epithelial cells is observed in IPF. CHOP (a marker of ER stress) is often activated in the terminal or pathological stage to induce activation of Caspase 3 usually leading to apoptosis. Thus, we hypothesize that overproduction of MUC5B in bronchoalveolar epithelia is associated with the ER stress response leading to cell death and progressive lung fibrosis. **Methods and Results:** Using RNAScope and immunofluorescence, we have found that different cell types express MUC5B, including a subset of type II epithelial cells in human lung tissues obtained from controls and patients with IPF. MUC5B has higher expression in IPF lungs than control lungs, and is strongly associated with honeycomb cysts, where we also found majority of CCSP-positive and a subset of SPC-positive cells producing MUC5B. Moreover, MUC5B is co-expressed with CHOP in airway epithelial cells as well as in a subset of SPC-positive cells in patients with IPF. Some MUC5B overexpressing cells in IPF patients co-express cleaved caspase 3, indicating mitochondrial damage. SHG for fibrillar collagen analysis showed increased fibrillar collagens depositions in patients with IPF. Local metabolic imaging via Fluorescent Lifetime Imaging Microscopy (FLIM) showed that patients with IPF have a shift of free/bound NADH lifetime towards increased free NADH in airway

epithelial cells and alveolar regions, indicating metabolic reprogramming of airway cells consistent with mitochondrial damage and thus impaired function. **Conclusions:** These results indicate that excess of MUC5B is associated with ER stress in the distal lung, which may cause mitochondrial impairment and apoptosis, followed by augmented lung fibrosis.

P680/B697

L-serine Protects Mouse Hippocampal Neuronal Ht22 Cells Against Oxidative Stress-mediated Mitochondrial Damage and Apoptotic Cell Death.

K. Kim, 41566[1], S. Hwang[1], S. Park[1], M. Kim[2], D. Jun[2], Y. Kim[1]; [1]Kyungpook National University, Daegu, KOREA, REPUBLIC OF, [2]Astrogen. Inc, Daegu, KOREA, REPUBLIC OF.

The cytoprotective mechanism of L-serine against oxidative stress-mediated neuronal apoptosis was investigated in mouse hippocampal neuronal HT22 cells. Treatment with the reactive oxygen species (ROS) inducer 2,3-dimethoxy-1,4-naphthoquinone (DMNQ) increased cytosolic and mitochondrial ROS and apoptosis, without necrosis, in HT22 cells. ROS-mediated apoptosis was accompanied by the induction of the endoplasmic reticulum (ER) stress-mediated apoptotic pathway, involving CHOP/GADD153 upregulation, JNK and p38 MAPK activation, and caspase-12 and caspase-8 activation, and subsequent induction of the mitochondrial apoptotic pathway through BAK and BAX activation, mitochondrial membrane potential (Δψm) loss, caspase-9 and caspase-3 activation, PARP cleavage, and nucleosomal DNA fragmentation. However, the DMNQ-caused ROS elevation and ER stress- and mitochondrial damage-induced apoptotic events were dose-dependently suppressed by co-treatment with L-serine (7.5−20 mM). Although DMNQ reduced both the intracellular glutathione (GSH) level and the ratios of reduced GSH to oxidized GSH (GSSG), the reduction was restored by co-treatment with L-serine. Co-treatment with GSH or *N*-acetylcysteine also blocked DMNQ-caused ROS elevation and apoptosis; however, co-treatment with the GSH synthesis inhibitor buthionine sulfoximine significantly promoted ROS-mediated apoptosis and counteracted the protection by L-serine. In HT22 cells, DMNQ treatment appeared to tilt the mitochondrial fusion-fission balance toward fission by down-regulating the levels of profusion proteins (MFN1/2 and OPA1) and inhibitory phosphorylation of profission protein DRP1 at Ser-637, resulting in mitochondrial fragmentation. These DMNQ-caused alterations were prevented by L-serine. A comparison of mitochondrial energetic function between DMNQ- and DMNQ/L-serine-treated HT22 cells showed that the DMNQ-caused impairment of the mitochondrial energy generation capacity was restored by L-serine. These results demonstrate that L-serine can protect neuronal cells against oxidative stress-mediated apoptotic cell death by contributing to intracellular GSH synthesis and maintaining the mitochondrial fusion-fission balance.

P681/B698

Genome-wide Crispri and Crispra Screens Identify Novel Factors Regulating Reactive Oxygen Species (ros) Homeostasis in Human Ipsc-derived Neurons.

R. Tian[1,2,3], M. Gachechiladze[4], C. Ludwig[2,3], J. Hong[2,3], R. Yan[5,3], K. Xu[5,3], M. Ward[4], M. Kampmann[2]; [1]Biophysics Graduate Program, University of California, San Francisco, San Francisco, CA, [2]Institute for Neurodegenerative Diseases, Department of Biochemistry and Biophysics, San Francisco, CA, [3]Chan-Zuckerberg Biohub, San Francisco, CA, [4]National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, MD, [5]Department of Chemistry, UC Berkeley, Berkeley, CA.

Reactive oxygen species (ROS) are highly reactive oxygen-derived radicals that can damage proteins, lipids, DNA and RNA. Excessive level of ROS has been implicated in aging and many neurodegenerative diseases. Neurons in the brain are especially vulnerable to ROS due to their high oxygen consumption, limited antioxidants and enriched polyunsaturated fatty acids (PUFA) that are susceptible to oxidation. However, how neurons maintain ROS homeostasis remains largely unknown. To systematically characterize factors that regulate ROS level in human neurons, we conducted multiple genome-wide CRISPR-based genetic screens. We first developed platforms that enable highly specific gene knockdown or overexpression in human neurons by integrating CRISPRi/a technologies with our previously established i^{3}N neuronal differentiation method that produce large amounts of homogenous glutamatergic neurons. Next, we conducted genome-wide loss-of- and gain-of-function screens in those neurons, including reporter-based screens on the level of ROS, and survival-based screens, in which neurons were cultured in normal medium or medium lack of antioxidants thus generating a condition of mild oxidative stress. From these screens, we identified novel genes that regulate ROS level or neuronal survival under oxidative stress. One of the top hits, prosaposin (encoded by gene *PSAP*), a lysosomal protein involved in gangliosides degradation, showed a strong increase of ROS level when knocked down in neurons. We further characterized that loss of *PSAP* leads to ganglisoides accumulation in enlarged lysosomes, enhanced autophagy and damaged mitochondria in a neuron-specific manner. *PSAP* knockout neurons are highly susceptible to the medium lacking antioxidants, which can be fully rescued by inhibiting lipid peroxidation by Ferrostatin-1 or iron chelation by Desferoxamine (DFO), but not by caspase inhibition, suggesting that ferroptosis but not apoptosis is induced in *PSAP* knockout neurons under oxidative stress. Furthermore, we identified ferroptosis signatures including dramatic accumulations of lipid peroxidation and iron, and decreased glutathione (GSH) level in *PSAP* knockout neurons. In summary, we developed CRISPRi and CRISPRa screening platforms in human iPSC-derived neurons and uncovered novel factors that regulate ROS level in human neurons through genome-wide CRISPR screens. Among all the novel hits, we elucidated the mechanism of *PSAP,* which provides novel links between gangliosides metabolisms, autophagy and ferroptosis.

P682/B699

A Small Molecule Piperazine Oxalate Derivative Compound Induces Er Stress-mediated Apoptosis through Activation of the Activating Transcription Factor 4-c/ebp Homologous Protein-death Receptor 5 Pathway.

S. Kim[1], S. Hwang[1], S. Park[1], I. Kim[2,3]; [1]Biomedical Research Center, ASAN Institute for Life Sciences, ASAN Medical Center, Seoul, KOREA, REPUBLIC OF, [2]Department of Convergence Medicine, University of Ulsan College of Medicine, Seoul, KOREA, REPUBLIC OF, [3]Convergence Medicine Research Center (CREDIT), ASAN Institute for Life Sciences, ASAN Medical Center, Seoul, KOREA, REPUBLIC OF.

Modulation of unfolded protein response (UPR) is an emerging target pathway to treat cancer for its cell death induction activity. In our procedure to isolate UPR-modulating small molecules, we previously reported a piperazine oxalate derivative compound (AMC-04) triggering enhanced phosphorylation of eukaryotic translation initiation factor-2 alpha (eIF2α). An d in this report, we found that AMC-04 induces apoptotic cell death *via* activation of UPR in human hepatocellular carcinoma and human breast cancer cells. Incubation of breast cancer cells with AMC-04 induces upregulation of activation transcription factor-4 (ATF4)-C/EBP homologous protein (CHOP) followed by death receptor 5 (DR5) expression which was revealed by microarray analysis, small-interference RNA analysis, and western blotting. In more mechanistic view, AMC-04 induced cytotoxic UPR pathway activation is mediated by reactive oxygen species (ROS) generation. Chemical informatics approach predicted that AMC-04 can bind and modulate activity of histone methyltransferases. Furthermore, chemical or genetic inhibition of predicted target proteins induced UPR activation with resulting apoptotic cell death suggesting inhibition of histone methyltransferase are promising targets for future cancer therapy. Taken together, we identified a new small molecule AMC-04 modulating epigenetic enzyme activity, and AMC-04 revealed a new molecular communication between UPR and histone modification.

P683/B700

Cellular Energy Stress Induces ROS-mediated Activation of RIP3.

H. Noh, 16499, H. Park, Y. Ha, M. Kim, Y. Lee, S. Hong, Y. Kim; Ajou University, Suwon-si, KOREA, REPUBLIC OF.

The receptor-interacting serine-threonine kinase 3 (RIP3) is key molecule in the programmed necrotic cell death pathway. In response to TNF stimulation, RIP3 interacts with RIP1 through a homotypic interaction motif (RHIM) and MLKL is recruited to assemble necrosome. This consequently induce necroptosis. Phosphorylation is one of the post-translational modification and plays role of switch turning signal on/off. RIP3 is serine/threonine kinase and it can be activated by autophosphorylation at Ser 227 residue under TSZ induced necroptosis. Since phosphorylated RIP3 is required to bind MLKL, activation of RIP3 is critical to induce necrotic cell death. To date, however, how phosphorylation of RIP3 is regulated has not been known yet. Almost cancer cell is exposed to energy stress condition. Under cellular energy stress condition, we observed the phosphorylation of RIP3. Also protein A, which is one of the candidate for kinase to be activation under energy stress condition, phosphorylates RIP3 and sequentially activates MLKL. Furthermore though RIP1 is indispensable in TNF induced necroptosis pathway, it is not required in this condition to activate RIP3 and MLKL. In a future study we investigate protein a as the one of the candidates to activate RIP3.

P684/B701

Cell Injury Leads to an Immediate Internal Calcium Release in Surrounding Astrocytes.

V. Gomez-Godinez, H. Li, A. C. Wu, I. E. Mao, A. M. Yang, E. Liang, A. Zhou, L. Shi, C. Wu, M. W. Berns; UCSD, La Jolla Ca, CA.

Astrocytes in the brain are rapidly recruited to sites of injury where they enclose the lesion, phagocytose damaged material and take up neurotransmitters and ions to avoid the propagation of damaging molecules. Excitatory molecules released from dying cells can lead to calcium dysregulation. Excessive calcium can cause mitochondrial depolarization and overload which can lead to necrotic cell death. We investigate the astrocytic response to nearby cell injury by utilizing a laser microscope system to induce cell death on a selected cell in an established astrocyte cell line. Our results show that astrocytes exhibit an immediate calcium spike. We hypothesize that the calcium spike in nearby cells is due to an internal release and influx from the outside. Glutamate is one of the excitatory molecules that is released from dying cells and can lead to a calcium influx through it's interaction with the NMDA receptor. We find that the NMDA antagonist MK801 decreases the intracellular calcium spike caused by a nearby cell injury. We also investigate the contribution of internal calcium release to the cytoplasmic spike through the use of a commercially available calcium free medium. Surprisingly, cells exhibited a calcium spike with greater amplitudes when compared to control cells in regular medium. Similarly, cells in calcium free hanks buffer saline solution are capable of exhibiting a calcium spike. Treatment with the Ip3 receptor antagonist and store operated calcium release modulator, 2-Aminoethoxydiphenylborane(2-APB) led to a decrease in the calcium spike when in regular and calcium free medium. These results support the internal release of calcium from the ER in astrocytes responding to injury or death in nearby cells.

P685/B702

Evaluation of Ph as a Factor in Vaam-mediated Cellular Distress and Death in *Euglena*.

A. Weikel, A. Mohamed, S. B. Redmond; Radford University, Radford, VA.

During the process of cellular respiration, cells generate a proton motive force (PMF). The PMF functions as a result of the electrochemical gradient found across the mitochondria's inner membrane, moving protons and electrons through a series of electron carrier proteins that, ultimately, provide power to ATP synthase. We observed Vespa Amino Acid Mixture (VAAM), a commercially available sports drink derived from Asian giant hornet larvae. VAAM is a suspected extreme coupler of the PMF and our previous studies have demonstrated increased production of ATP and reactive oxygen species under VAAM treatment, and death in both cells and invertebrates treated with VAAM. We are interested to see if VAAM is toxic to cells due to mitochondrial membrane disruption or due to the acidity of VAAM. VAAM suspended in tap water (as for *Euglena* incubation) has a pH of 3.6 at 0.6%, 3.6 at 0.3%, and 5.6 at 0.03% concentrations. *Euglena* were tested for survivability in the presence of VAAM, citric acid, and hydrochloric acid (HCl) at three different concentrations. *Euglena* have been shown to break down their flagella and enter a balled state when in toxic environments, this has been noted as cellular distress, and disrupted membranes have been noted as cellular death. We found that at 0.6%, 0.3%, and 0.03% VAAM *Euglena* cells show distress and cellular death compared to pH matched solutions of citric acid and HCl, which when tested did not show cellular distress or death. Death was expected to increase over time during the assay, so each trial (n = 3/treatment) was observed at 5, 15, and 30-minute intervals for signs of cellular death. It was found that *Euglena* showed increased cellular distress in response to

VAAM at 30 minutes relative to the 5- and 15-minute intervals. We conclude that while the amino acid mixture in VAAM does alter pH, pH is not sufficient to cause cell distress and death in the absence of VAAM.

P686/B703

Bap31 Inhibits Cell Adaptation to Er Stress Conditions, Negatively Regulating Autophagy Induction by Interaction with Stx17.

K. Machihara, T. Namba; Kochi university, Kochi, JAPAN.

Cancer cells modulate their metabolism to proliferate and survive under nutrient limitation and anaerobic stress conditions, and to induce cellular reactions such as unfolding protein response (UPR) and autophagy. UPR maintains and restores endoplasmic reticulum (ER) homeostasis to increase protein secretion by inducing the ER chaperons that mediate protein refolding and degrade unfolded proteins. However, irreversible ER stress induces cell death to eliminate damaged cells. Autophagy can play a crucial role in cellular adaptation to starvation. By recycling metabolites, autophagy provides a source of energy and basic factors for the biosynthesis of new macromolecules. Therefore, resistance to ER stress and the induction of autophagy is essential for tumor proliferation and survival, and the suppression of these processes is an important “metabolic checkpoint” for the elimination of cancerous cells; however, the molecular mechanism by which cancerous cells avoid the metabolic checkpoint is not fully understood. B-cell receptor associated protein 31 (BAP31) is an integral ER membrane protein that functions in a number of apoptotic pathways. Recently, we discovered that BAP31 regulates mitochondrial function and metabolic pathways, such as autophagy, by communication with ER and mitochondria via contact sites; however, the role of BAP31 in the metabolic checkpoint and cancerous phenotype is not fully understood. This study reports that BAP31 inhibits resistance to metabolic stress in cancer cells, induces cell death via ER stress, and acts as a tumor suppressor factor by suppressing autophagy via the metabolic checkpoint. The loss of BAP31 increased autophagy and suppressed ER stress-induced cell death. The autophagy related protein (ATG) family and the ER-resident SNARE protein syntaxin 17 (STX17) are well-known factors in the induction of autophagy signaling. BAP31 interacts with STX17, which suppressed the induction of autophagy by suppressing interaction with STX17 and ATG14L. Moreover, BAP31-knockout enhances invasion activity and tumor growth in metabolic stress conditions *in vivo* compared to BAP31 expressing cells. Therefore, BAP31 can be considered a novel tumor suppressor factor involved with metabolic stress, inducing cell death via the ER stress response and suppressing autophagy by inhibiting STX17 and ATG14L interaction.

P687/B704

A CRISPR Screen Identifies Essential Mediators of Hydrogen Peroxide-induced Cell Death.

T. Chidawanyika, K. Mark, S. Supattapone; Geisel School of Medicine at Dartmouth, Hanover, NH.

Hydrogen peroxide (H_2O_2) is a key regulatory molecule in cellular redox biology. When present at homeostatic concentrations, H_2O_2 can act as a signaling molecule for cell survival, proliferation and differentiation. However, when present at pathologically higher concentrations, H_2O_2 can cause oxidative stress which results in the damaging of proteins, lipids and DNA. This oxidative damage lead to cell death if the stress is not alleviated. Genes that are required for the execution of H_2O_2-induced cell death are currently unknown. Consequently, we conducted a comprehensive CRISPR-based positive selection screen to identify genes that are essential for H_2O_2-induced cell death in HAP1 cells. Our screen

revealed several genes that are involved in the generation of reactive oxygen species as necessary mediators of H_2O_2-induced cell death. Since H_2O_2has important implications for diseases that arise from oxidative stress such as cancer, myocardial infarction, and neurodegenerative diseases, our findings not only provide important insights on redox biology, but they may also inform avenues for therapeutic interventions for some of these diseases.

Regulation of Aging

P688/B705

Prmt7 Methylates and Suppresses Gli2 Binding to Sufu Thereby Promoting Its Activation.

A. T. Vuong, Male; Shool of Medicine, Sungkyunkwan University, 2066 Seoburo, Suwon, KOREA, REPUBLIC OF.

Cellular senescence is implicated in aging or age-related diseases. Sonic hedgehog (Shh) signaling, an inducer of embryonic development, has recently been demonstrated to inhibit cellular senescence. However, the detailed mechanisms to activate Shh signaling to prevent senescence is not well understood. Here, we demonstrate that Protein arginine methyltransferase 7 (PRMT7) promotes Shh signaling via GLI2 methylation which is critical for suppression of cellular senescence. PRMT7-deficient mouse embryonic fibroblasts (MEFs) exhibited a premature cellular senescence with accompanied increase in the cell cycle inhibitors p16 and p21. PRMT7 depletion results in reduced Shh signaling activity in MEFs while PRMT7 overexpression enhances GLI2-reporter activities that are sensitive to methylation inhibition. PRMT7 interacts with and methylates GLI2 on arginine residues 225 and 227 nearby a binding region of SUFU, a negative regulator of GLI2. This methylation interferes with GLI2-SUFU binding, leading to facilitation of GLI2 nuclear accumulation and Shh signaling. Taken together, these data suggest that PRMT7 induces GLI2 methylation, reducing its binding to SUFU and increasing Shh signaling, ultimately leading to prevention of cellular senescence.

P689/B706

Shh Signaling Regulates Cell Structure and Terminal Differentiation of Mouse Intervertebral Disc Cells.

C. Dahia[1], S. Mohanty[2]; [1]Weill Cornell Medical College, Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, NY.

Sonic hedgehog (SHH) expressed by the notochord is a crucial regulator of embryogenesis. Using a mouse model system, we showed that the notochord descendant nucleus pulposus cells (NP) continue to express SHH in the center of each intervertebral disc (IVD), and throughout the spine. IVD degeneration is a major cause of back pain, but with no effective treatments, due to poor knowledge about the molecular and cellular processes that regulate healthy IVD. We also showed that SHH continues to be an important signaling molecule and regulate the growth, differentiation by way of extracellular matrix production, and structure of the neonatal mouse disc. Recently we found that with aging the expression of SHH reduced, which is associated with the differentiation of large uninucleated NP cells into small-multinucleated syncytium as shown by lineage-tracing studies. In the current study, we test the hypothesis that SHH is crucial for the maintenance of NP cells structure and function and whether it can regulate cellular plasticity to prevent or revert the pathological multinucleated phenotype of the NP cells. First using Shh reporter mice, we found that although SHH was expressed by all notochordal cells, in adult mouse, SHH is expressed only by a subset of NP cells. Next, to test whether

even at low level whether SHH maintains the disc health, we conditionally targeted Shh in adult mouse NP cells and found that within two months large uninucleated NP cells differentiated into small-multinucleated syncytium. Then we using tet-on system we conditionally and transiently overexpressed recombinant Shh (rShh) in the adult mouse NP cells and allowed the mice to age for another six months. While the NP cells of the control mice underwent pathological changes to form a multinucleated syncytium, those of the rShh mice maintained their large uninucleated structure. Finally, using a SmoM2 allele, we conditionally activated hedgehog signaling in the NP cells of aged mice when the NP cells normally changed from large uninucleated cells into small-multinucleated syncytium and analyzed the discs one month later. Interestingly, all NP cells were large and uninucleated again. The change in NP cell phenotype in all the genetic experiments was associated with regulation of downstream targets of SHH, including patched1, Gli1, and extracellular matrix proteins. These findings show that SHH regulates cellular plasticity of NP cells, and has the potential to rejuvenate degenerating discs.

P690/B707

Alteration of Fatty Acids Oxidation by Increased Cpt1a on Senescent of Placenta-derived Mesenchymal Stem Cells by Long-term Cultivation.

J. Seok[1], H. Jung[1], J. Kim[1], J. Jun[1], J. Cho[1], S. Jun[1], S. Kim[1], S. Park[1], J. Lee[2], C. Kim[3], G. Kim[1]; [1]CHA University, Seongnam, KOREA, REPUBLIC OF, [2]Korea University, Seoul, KOREA, REPUBLIC OF, [3]University of Ulsan College of Medicine, Seoul, KOREA, REPUBLIC OF.

Human placenta-derived mesenchymal stem cells (PD-MSCs) have potentials including self-renewal activity as well as differentiation into several lineages for powerful sources for cell therapy in regenerative medicine. Nevertheless, PD-MSCs shows limited lifespan according to long-term cultivation and are well unknown on cellular mechanism related to mitochondrial function. Therefore, the objectives in the study are to compare differences including alteration in cellular metabolism as well as mitochondrial function between early passage (<passage.8, Early) and late passage (<passage.14, Late) of PD-MSCs and investigate whether the expression of CPT1A is associated with mitochondrial dysfunction observed in senescent of PD-MSCs by long-term cultivation. Also, immortalized PD-MSCs (by overexpressed hTERT gene transfection) after passage number 14 were positive control of non-senescent cells. We analyzed the characterization of PD-MSCs for stemness, differentiation, cell death (e.g., apoptosis and autophagy) and mitochondrial function by qRT-PCR, western blot, Elisa, immunofluorescence and XF-assay compared with “Early” PD-MSCs. The “Late” PD-MSCs decreased the expression of stemness markers including differentiation and proliferation, otherwise the expression of senescent markers such as SA-β-gal and p21 including cell death increased compare with “Early” PD-MSCs (*p<0.05). Also, ROS, ATP production, mitochondrial membrane potential (MMP) and cellular metabolism, which are involved in mitochondrial function, were decreased in “Late” PD-MSCs compared to those of “Early” PD-MSCs (*p<0.05). Interestingly, “Late” PD-MSCs increased the expression of CPT1A, p-ACC and PPARα, which involved in mitochondrial metabolism of fatty acid, compared to those of “Early” PD-MSCs (*p<0.05). Down-regulated CPT1A by inhibitor in “Late” PD-MSCs increased MMP and decreased mitochondrial mass, ROS and ATP production compared to control (*p<0.05). Moreover, inhibited of CPT1A in PD-MSCs were increased and glucose and fatty acid mechanism were decreased compared with control (*p<0.05). These findings mean that CPT1A play as an important factor in mitochondrial function via regulation of energy metabolism and ROS level in replicative senescence of PD-MSCs according to long-term cultivation. Therefore, these data help understanding the fundamental mechanism of self-renewal of MSCs and support to overcome the replicative senescence of MSCs. This

work was supported by the National Research Foundation of Korea Grant funded by the Korean Government (F19SN22T1305) This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Science, ICT & Future Planning (NRF-2017M3A9B4061665).

Metformin Alleviates Altered AMPK Activity Associated with a Missense Mutation in Ctrp5 Underlying Late-onset Retinal Degeneration.

M. Nimmagadda[1], K. J. Miyagishima[1], R. Sharma[1], K. Clore-Gronenborn[1], Z. Qureshy[1], D. Ortolan[1], D. Bose[1], C. Zhang[1], M. Farnoodian[1], B. Jun[2], R. Sharp[3], C. Cukras[1], P. Sieving[1], N. Bazan[2], K. Boesze-Battaglia[3], S. Miller[1], K. Bharti[1]; [1]National Eye Institute, NIH, Bethesda, MD, [2]Louisiana State University School of Medicine, New Orleans, LA, [3]University of Pennsylvania, Philadelphia, PA.

Late-onset retinal degeneration (L-ORD) is a rare disease that shares clinical phenotypes with age-related macular degeneration (AMD). Previous reports have linked compromised functionality of the retinal pigment epithelium (RPE), a critical retina layer, to the initiating events of retinal degeneration. The RPE maintains the health and integrity of the lipid and carbohydrate rich photoreceptors, and its degeneration is likely the cause of altered lipid metabolism observed in L-ORD and AMD disease pathologies. L-ORD stems from a missense mutation in CTRP5, which is highly expressed in the RPE. Using induced pluripotent stem cell (iPSC) technology, we differentiated iPSC-RPE (iRPE) cells from fibroblasts of L-ORD patients and their unaffected siblings. Mutant CTRP5, in L-ORD patient iRPE, had reduced binding affinity for adiponectin receptor 1 (AdipoR1), which led to elevated levels of pAMPK under baseline conditions (cells fed with 5% fetal bovine serum containing media). However, under conditions of further metabolic stress (ex. serum starvation or alterations to the ratio of ATP to AMP) L-ORD patient iRPE did not exhibit any additional increases in pAMPK levels. This metabolic dysfunction caused L-ORD patient iRPE to dedifferentiate and enter the process of epithelial to mesenchymal transition. Administration of metformin, an anti-diabetic drug, to L-ORD patient iRPE rescued the cells from EMT, resensitized AMPK activity, and improved lipid metabolism. Furthermore, a retrospective clinical study showed that patients ages 50-59, who had been prescribed Metformin, experienced a delayed age of onset for exudative AMD by two years. With this, we believe that metformin could be a promising course of treatment to mitigate some cellular metabolic stress that emerges during the initiating events of AMD-like retinal diseases.

Dysregulation of Nsun2 Promotes Pathological Tau Alterations in Alzheimer's Disease.

Y. A. Kim[1,2], I. Santa-Maria[1,2]; [1]Taub Institute for Research on Alzheimer's Disease and the Aging Brain, New York, NY, [2]Department of Pathology and Cell Biology, Columbia University, New York, NY.

Background: Currently, the molecular basis of Alzheimer's disease (AD) are unclear. However, several studies suggest that altered microRNA (miRNA) expression and/or function plays an important role in the pathogenesis of AD by altering tau proteostasis. MiRNAs are a part of vital regulatory mechanism that prevents the deposition of tau protein. However, mechanisms governing how miRNAs are regulated in the brain are poorly understood. Methylation is a prevalent posttranscriptional modification found in coding and non-coding RNAs that regulates accuracy of translation initiation, stability and biogenesis or processing. Recently, miRNAs have also been found to be targets of RNA methylation. One of the

methyltransferases specifically enriched in the brain is NSUN2. Importantly, deficits in memory and learning have been observed in NSUN2-deficient *Drosophila melanogaster* model and transgenic mice NSUN2 knockout model, indicating a potential role of NSUN2 in cognitive function. Notably, in humans, mutations in the NSUN2 gene can cause disorders that are associated with intellectual disability. Therefore, our objective is to investigate the role of RNA methyltransferase, NSUN2 in tau proteostasis regulation. **Methods:** Here we performed histological and biochemical analyses of post-mortem human brains from AD patients and healthy controls. In order to mimic pathological conditions of AD brain *in-vitro*, we treated primary neuronal cultures with synthetic oligomeric Amyloid beta (Aβ) and analyzed the effects of alterations in the levels of NSUN2 on tau proteostasis using a myriad of immunocytochemical and biochemical approaches. In addition, we chose *Drosophila* as our *in-vivo* model system to study NSUN2-microRNA modulation of tau neurotoxicity and behavior. **Results:** Our data supports dysregulation of NSUN2 in post-mortem brain tissue from AD patients when compared to healthy controls. In addition, we found that oligomeric Aβ induces both dysregulation of NSUN2 and changes in tau proteostasis in primary neuronal cultures. Furthermore, bioinformatic analysis shows predicted methylation sites in miRNAs that have been implicated in AD. Strikingly, our *in-vivo* data shows that overexpression of NSUN2 can rescue tau induced toxicity. **Conclusion:** We propose that NSUN2 mediates methylation of brain miRNAs promoting alterations in tau proteostasis leading to neurodegeneration and cognitive dysfunction. Discovering the earliest events driving alterations in tau proteostasis will identify possible therapeutic targets to slow and/or halt the progression of the disease.

P693/B710

Vascular and Neurogenic Rejuvenation in Aging Mice by Modulation of Asm.

J. Bae, J. Lee, K. Park, W. Han, H. Jin; Kyungpook Natl University Med Sch, Daegu, KOREA, REPUBLIC OF.

Although many reports have revealed dysfunction of endothelial cells in aging, resulting in blood-brain barrier (BBB) breakdown, the underlying mechanism or mechanisms remain to be explored. Here, we find that acid sphingomyelinase (ASM) is a critical factor for regulating brain endothelial barrier integrity. ASM is increased in brain endothelium and/or plasma of aged humans and aged mice, leading to BBB disruption by increasing caveolae-mediated transcytosis. Genetic inhibition and endothelial-specific knockdown of ASM in mice ameliorated BBB breakdown and neurocognitive impairment during aging. Using primary mouse brain endothelial cells, we found that ASM regulated the caveolae-cytoskeleton interaction through protein phosphatase 1-mediated ezrin/radixin/moesin (ERM) dephosphorylation and apoptosis. Moreover, mice with conditional ASM overexpression in brain endothelium accelerated significant BBB impairment and neurodegenerative change. Overall, these results reveal a novel role for ASM in the control of neurovascular function in aging, suggesting that ASM may represent a new therapeutic target for anti-aging.

P694/B711

Assessing the Genetics of Aging in the *Drosophila* Midgut.

K. Plevock Haase, S. Bice, H. Lee, M. Serpe, M. Dasso, A. Arnaoutov; National Institute of Child Health and Human Development, NIH, Bethesda, MD.

Aging is characterized by the progressive decline in physiological processes, including gene misregulation and loss of tissue structure and function. The mechanisms that drive aging are poorly understood. The *Drosophila* posterior midgut has emerged as an excellent model for aging given its

highly stereotypical yet simple architecture. Similar to the mammalian intestinal epithelium, the *Drosophila* midgut epithelium is controlled by intestinal stem cell proliferation and the differentiation of their progeny. The midgut contains only four basic cell types: Intestinal stem cells give rise to either enteroendocrine cells or enteroblasts which then differentiate into enterocytes (large absorptive cells). As *Drosophila* age, there is a marked decrease in the levels of adherens junctions between enterocytes as well as accumulation of undifferentiated progenitor cells. To understand how this phenotype arises, it is important to understand the gene expression changes that are occurring with age. RNA-Seq of young and old flies has unveiled a number of novel genes whose expression demonstrates the same direction of age-dependent changes regardless sex or rearing condition (up or down). To understand how candidate genes influence gut health during aging, we use the GAL4/UAS system to perform RNAi and overexpression screens. To monitor the effect of gene expression on gut health, we assessed both gut morphology and the expression profiles of other age-regulated genes. For the former, we analyzed the integrity of cell-cell contacts and accumulation of stem/progenitor cells using immunofluorescence (IF) analysis of midguts from young (7d) and old (40d) flies. For the latter, we performed RNA-Seq analysis on midguts at the same timepoints. Through these screens, we have identified genes whose knockdown improved gut health outcomes as monitored both by IF and RNA-Seq. We are currently working to pinpoint the cell type(s) in which expression of these genes is most crucial. Our future studies will analyze the mechanisms through which these candidates influence gut aging and overall organism health.

***Ecto*-5´-nucleotidase (CD73) Supports AMPK Activation in Hepatocytes during Physiological Liver Aging.**

K. P. Alcedo, H. H. Willcockson, M. Minor, D. Fu, K. Greene, N. T. Snider; University of North Carolina, Chapel Hill, NC.

The enzymatic dephosphorylation of 5´-nucleotides, such as adenosine 5´-monophosphate (AMP) is a key step in purine salvage and purinergic signaling. This reaction occurs inside the cell or in the extracellular space. *Ecto*-5´-nucleotidase (CD73) is the major enzyme catalyzing the formation of extracellular adenosine from AMP. CD73-generated adenosine controls tissue homeostasis and responses related to inflammation, ischemia, fibrosis, and cancer. Adenosine is particularly important for metabolic homeostasis in the liver, but the specific functions of CD73 in liver homeostasis have not been elucidated. The objective of the present study was to establish a liver-specific CD73 knockout model and use it to evaluate the in *vivo* roles of CD73 in hepatocytes. We generated a hepatocyte-specific CD73 knockout mouse model (cKO) on the C57/BL6 background using the Cre-lox system. Male and female WT and cKO mice and liver tissues were compared by serological, histological, and biochemical methods. Primary hepatocytes were isolated from the mice and grown in 3D culture for molecular and imaging analyses. Loss of hepatocyte CD73 resulted in 70-80% reduction in total liver CD73 protein ($p<0.0001$). CD73 loss was associated with a significant decrease ($p<0.01$) in the activity of AMP-activated protein kinase (AMPK), assessed by substrate profiling. *Ex vivo* studies in primary hepatocytes showed that AMPK activity is dependent on extracellular adenosine, generated by CD73 and taken up intracellularly by the equilibrative nucleoside transporter ENT1. Male and female cKO mice developed normally for up to 21 weeks of age without displaying significant liver phenotypes. However, between 21-41 weeks of age, the cKO mice developed spontaneous liver injury with elevations in serum liver injury markers ($p<0.05$ in males; $p<0.15$ in females). A significant increase in lobular inflammation

and hepatocyte ballooning degeneration were observed in male cKO mice compared to male WT mice ($p<0.05$). Although AMPK hypo-activation was also observed in the livers from female cKO mice, they did not display a statistically significant difference in liver injury compared to female WT mice. A compensatory induction in adenosine receptor expression that was present in female, but not male, cKO mice may partially explain the sex differences in the development of spontaneous liver injury. In conclusion, we developed a novel mouse model to address the importance of extracellular adenosine production by hepatocytes. Furthermore, we showed that this pathways is critical for sustaining AMPK activity in the aging liver via an outside-in signaling mechanism mediated by CD73.

P696/B713

Widespread Accumulation and Aggregation of IF Proteins during Mammalian Aging and Partial Reversal by Lifelong Caloric Restriction.

J. Robinson, H. Willcockson, R. Battaglia, N. Snider; UNC at Chapel Hill, Chapel Hill, NC.

Background and hypothesis: Intermediate filament (IF) proteins are critical regulators of cellular function and are prone to misfolding and aggregation under chronic stress conditions. Many late-onset diseases exhibit perturbed proteostasis, which is one hallmark of cellular stress. Caloric restriction (CR) increases stress resistance and slows aging in multiple organisms, including non-human primates. We hypothesized that mammalian IF proteins accumulate at an organism-wide level in response to aging stress. **Methods:** We compared tissue-specific IF gene and protein expression in young (3 months old) and old (24 months old) mice from three genetic backgrounds (CBA, BALB/c and CB6F1). Brain, heart, lung, liver, intestine, pancreas, kidney and spleen tissue from male and female mice (n=3 for each sex/strain) were used for RNA and protein extraction. Tissues and serum were additionally collected from 12- and 24-month old male C57BL/6J mice that were raised on an unrestricted (ad lib; AL) or a 30% CR diet (n=3/group). Study animals were provided by the National Institute of Aging and used under an approved protocol. We used sequence-specific primers and qPCR to measure mRNA levels of *Gfap, Nefl, Nefm, Nefh, and Nes* in brain; *Des* in heart; *Vim* in heart and spleen; and *Krt8* in lung, liver, intestine, pancreas and kidney. Parallel immunoblotting on total tissue lysates compared monomeric and high molecular mass (HMM) IF protein aggregates under reducing and non-reducing conditions. **Results:** All IF proteins showed accumulation in aged animals at the level of the monomer, HMM aggregates, or both. The most prominent were changes in the heart (desmin) and lung tissue (K8). Desmin monomer (50 kDa) and HMM oligomers (>250 kDa) increased 11-fold and 7-fold, respectively in heart lysates from old versus young mice independent of sex and strain ($p<0.001$). CR diet mice had significant reduction ($p<0.05$) in serum glucose compared to AL mice (300+36 vs. 181+9 mg/dL; non-fasting state) and had 5-fold and 2-fold decrease in HMM desmin at 12 and 24 months of age, respectively ($p<0.01$). Old mice exhibited >7-fold in HMM K8 (>250 kDa) in lung tissues irrespective of sex and strain ($p<0.01$), while CR mice had 2.5-fold decrease in K8 aggregates in the lungs at 12 and 24 months (n=3/group, $p<0.01$). In general, mRNA levels did not follow protein expression changes during aging, suggesting post-translational mechanisms. **Conclusions:** We reveal widespread accumulation of IF proteins in aged mice regardless of sex or strain, and partial reversal by caloric restriction and improved glucose homeostasis.

P697/B714

Assessing the Role of the Progeria Associated BAF A12T Variant on Nuclear Envelope Integrity, Chromatin Conformation and Genotoxic Stress.

M. F. El-Sabban, P. Traktman; Medical University of South Carolina, Charleston, SC.

Among the defined hallmarks of cellular aging are DNA damage, genomic instability, epigenetic alterations, cellular senescence, oxidative stress and stem cell exhaustion. Premature aging syndromes (progerias) are useful models to complement the study of physiologic aging. A subset of premature aging syndromes arises from mutations in the components of the nuclear envelope resulting in what is known as a nuclear envelopathy. The most common and best studied of these progerias, Hutchinson Gilford Progeria Syndrome (HGPS), arises from an autosomal dominant lamin A/C mutation that leads to the accumulation of a variant of lamin a and a characteristic nuclear envelopathy. More recently, Nestor Guillermo Progeria Syndrome (NGPS) has been identified, resulting from the homozygous inheritance of a BANF1 mutation causing an Ala-Thr substitution at residue 12 of the BAF protein ($A^{12}T$). BAF is a small, essential, dimeric dsDNA-binding protein that serves as a bridge between interphase chromatin and the nuclear envelope. BAF has been implicated in regulating chromatin conformation and the DNA damage response and also participates in the recognition and repair of nuclear envelope ruptures and the enclosure of mitotic chromosomes in a single nuclear envelope. NGPS patient-derived fibroblasts exhibit nuclear envelopathy, and patients exhibit signs of premature aging, including progressive osteolysis and loss of subcutaneous fat. Our interest lies in the overlap between disruptions in the nuclear envelope, chromatin conformation and genotoxic stress. To address the cellular and organismal pathology of NGPS, we have used CRISPR/Cas9 technology to establish BAF^{A12T}/BAF^{A12T}human induced pluripotent stem cells (hiPSCs). The BAF^{A12T}iPSCs appear normal, but in comparison to isogenic control cells, their ability to differentiate into mesenchymal stem cells (MSCs) in vitro is incomplete. BAF^{A12T}MSCs exhibit a marked increase in cellular senescence and an elevated cellular stress response. We are addressing the underlying cause of the senescent phenotype as well as monitoring BAF^{A12T}-induced changes in chromatin conformation, DNA damage and oxidative stress. We have also used CRISPR/Cas9 technology to establish a colony of BAF^{A12T}/+ mice. Mice that are homozygous for the $BAF^{A12T/A12T}$allele are viable and primary cultures of fibroblasts derived from the ears of mice are not senescent and do not demonstrate elevated basal DNA damage; however, these cells do show a marked nuclear envelopathy. Further characterization of these fibroblasts as well as mouse-derived MSCs are planned. Taken together, these in vitro and in vivo studies are aimed at uncovering the cellular and organismal impact of the BAF ^{A12T}mutation.

P698/B715

Effects of Age-dependent Changes in Cell Size on Endothelial Cell Growth through Yap1.

A. Mammoto, T. Mammoto; Medical College of Wisconsin, Milwaukee, WI.

Introduction:The aging population is rapidly growing. Aging is associated with impaired angiogenesis - the growth of new blood capillaries- and contributes to the increased susceptibility to various diseases. Thus, in order to develop more efficient therapies for aging-associated diseases, we need to understand the mechanisms by which aging impairs angiogenesis. In addition to soluble angiogenic factors, biophysical factors such as changes in cell size and geometry control endothelial cell (EC) growth and differentiation. A Hippo signaling transducer, Yes-associated protein (YAP1), acts as a mechanosensitive transcriptional co-activator and controls angiogenesis and organ regeneration. Methods: We use silver

nitrate staining and immunocytochemical analysis to measure the EC size in blood vessels ex vivo and in vitro. To directly examine the effects of cell size on YAP1 activity and EC proliferation and senescence, we use the microcontact printing system and culture young vs. Aged ECs on each island. Results: We have found that pulmonary artery ECs in aged mice are significantly larger than those in young mice. Aged human adipose tissue ECs are also larger than those in young adults. A major focal adhesion protein, paxillin, distributes at the distal ends of actin stress fibers in young ECs, while paxillin is localized along the actin fibers in the cytoplasm in aged ECs. The levels of YAP1 decrease and EC senescence is induced in aged ECs. The activity of CDC42, which controls actin cytoskeleton structures, is also higher in aged ECs compared to that in young ECs. To analyze whether age-related changes in EC size control YAP1 activity and EC senescence, we culture ECs on the microcontact-printed substrates consisting of square fibronectin-coated single-cell sized islands. When we culture aged human adipose ECs on large islands of size comparable to aged EC, YAP1 is excluded from the nucleus and EC proliferation is attenuated. Reduction of the aged EC size by culturing on smaller islands restores YAP1 nuclear localization, decreases Cdc42 activity, and inhibits EC senescence. Stimulation of YAP1 or inhibition of Cdc42 activity in aged ECs also restores blood vessel formation. These results suggest that age-dependent increases in EC size stimulate aged EC senescence through CDC42-YAP1 signaling. Conclusion: Modulation of EC size and/or Cdc42 and YAP1 activity will reverse age-related decline in angiogenesis and will lead to the development of promising strategies for age-dependent diseases.

P699/B716

A Role for Unc-45 in Maintaining Myosin during Aging.

C. Christian, H. Qadota, G. Benian; Emory University, Atlanta, GA.

UNC-45 is a chaperone required for the folding of functional myosin heads and the proper assembly of myosin into thick filaments. UNC-45 was first discovered in *C. elegans* and later found to be conserved in all animals. UNC-45 consists of a TPR domain that interacts with HSP-90, a central domain, and a UCS domain that interacts with and folds the myosin head. In addition to its essential role in muscle development, we hypothesize that UNC-45 has a role in mature muscle, to re-fold myosin heads damaged from thermal or oxidative stress. One type of stress is aging, as a popular theory is that the decline in cellular function found in aging is due to an accumulation of damage to macromolecules that occurs with time. Sarcopenia is the decreased muscle mass and function seen in the elderly in the absence of any underlying disease. Herndon et al. (2002) showed that *C. elegans* can serve as a model for sarcopenia. Using immunostaining with antibodies to myosin heavy chain a (MHC A), we show that there is a gradual decline in the number of A-bands (a measure of thick filament assembly) beginning at day 8 adults. By day 12 and especially day 16, there is also disorganization of A-bands. This disorganization appears similar to that of *unc-45* ts mutants grown at the restrictive temperature. By quantitative western blotting, we examined the levels of UNC-45, HSP-90, MHC a and MHC B, and found that all decline with age. Whereas MHC a and HSP-90 show a gradual decline, UNC-45 shows a major decline between days 3 and 4, and MHC B shows a major decline between days 4 and 8. Since the steady state *unc-45* transcript level shows either no change or an increase during aging, this suggests an increase in UNC-45 degradation over time. Unlike *unc-45*, *hsp-90* transcript levels decrease along with the protein. We also observe a decrease in UNC-45 protein, but not mRNA, in an *hsp-90* loss of function mutant, suggesting a role for HSP-90 in UNC-45 regulation and/or protein stabilization. Preliminary results indicate that UNC-45 protein and transcript increase with heat stress, providing further support for the role of UNC-45 in re-folding myosin heads after stress. We are testing the hypothesis that at least

some of the decrease in myosin heavy chain levels and thick filament assembly that occurs with aging is due to a decline in the level of UNC-45.

P700/B717

Using Zebrafish to Correlate Hair-cell Presynaptic Activity with Ototoxin Resistance.

D. Lukasz, K. S. Kindt; National Institutes of Health, Bethesda, MD.

Hair cells, the primary sensory cell of the auditory system, rely on calcium for their development and function. Exposing these cells to known ototoxins such as aminoglycoside antibiotics can cause irreversible hearing loss. Differential susceptibility to aminoglycosides has been reported in hair cells of various species including those of the zebrafish lateral line, but the mechanism behind this phenomenon is unknown. Functionally, sensory stimuli activate hair cells by eliciting the opening of basal presynaptic calcium channels followed by glutamate release onto afferent neurons. We have discovered that this synaptic activity is only detectable in approximately 30% of zebrafish hair cells and classified these as synaptically “active”. Because of the importance of calcium homeostasis in hair-cell survival, we hypothesized that differential susceptibility to aminoglycoside ototoxicity in zebrafish hair cells may be related to the presence or absence of presynaptic calcium signals. To explore this further, we are conducting functional calcium imaging in transgenic zebrafish expressing genetically encoded calcium indicators (GCaMPs) in external lateral-line hair cells. GCaMP imaging enables us to measure evoked presynaptic calcium signals within hair cells in *vivo*. After collecting activity measurements, we apply the aminoglycoside neomycin or neomycin-Texas Red solution to larvae, track cell survival, and draw correlations between survival, activity, and drug uptake. We are complementing these analyses by employing genetic mutants or pharmacological agents that chronically or transiently block presynaptic calcium signaling, respectively. Currently, we have found that synaptically “active” cells are more resistant to aminoglycoside ototoxicity. Additionally, the majority of “active” cells contain significantly less neomycin than “inactive” cells. Although the exact mechanism behind this is unclear, our preliminary data suggests that “active” cells have a younger cumulative age, rendering them more resilient to aminoglycosides. We have examined the relationship between presynaptic calcium signaling and aminoglycoside ototoxicity more closely following the chronic or acute disruption of presynaptic calcium. We found that chronic but not acute disruption of this activity actually augments cell survival. We are currently expanding our analyses to investigate the relationship between presynaptic activity, cumulative cell age, and cell death mechanisms. Overall, understanding how activity-dependent signals provide protection is critical to the development of otoprotective or even regenerative therapies.

P701/B718

Identification of Novel Interacting Proteins of Small Heat Shock Rotein Hspb5 by Using Bioid2 Method.

M. Nishihara[1], S. Ueda[1], K. Yoshino[2,3], A. Takeuchi[4], M. Yamanoue[1], Y. Shirai[1]; [1]Department of Agrobioscience, Kobe University, Japan, Kobe, JAPAN, [2]Biosignal Research Center, Kobe University, Japan, Kobe, JAPAN, [3]Department of Medical, Kobe University, Japan, Kobe, JAPAN, [4]Analytical Laboratory, Kobe Pharmaceutical University, Japan, Kobe, JAPAN.

HSPB5 belongs to a small heat shock protein (HSPB) family and highly expressed in skeletal muscle. HSPB5 is regulated by the phosphorylation with various cellular stresses and exhibits a cytoprotective function. Since HSPB5 expression is markedly increased in skeletal muscle of aging mice, it is speculated that HSPB5 plays a role in the endoplasmic reticulum (ER) stress by senescence. To elucidate the

resistance of HSPB5 to cell senescence, we searched for the binding protein of HSPB5 by using biotin enzyme labeling with BioID2. HSPB5-BioID2 biotinylated a protein near HSPB5 under ER stress conditions with the proteasome inhibitor MG132. After digestion of the cell lysate with trypsin, the biotinylated peptides were purified with tamavidin 2-REV beads and subjected to nanoLC-MS/MS. As a result, 91 biotinylated proteins were identified. In this study, we examined polo-like kinase 2 (PLK2), an apoptosis-related enzyme, as a candidate for a new binding protein. After MG132 treatment, HSPB5 and PLK2 protein expression levels were increased and co-localization was observed in the ER in myocytes. The binding of HSPB5 and PLK2 by MG132 treatment was confirmed by immunoprecipitation. Moreover, PLK2 inhibitor BI2536 suppressed HSPB5 phosphorylation and translocation of HSPB5 to ER by MG132. These results suggest that HSPB5 translocates to the ER through the phosphorylation by PLK2 and plays some cytoprotective function against ER stress.

P702/B719

Cellular Mechanisms of Aging within the Stem Cell Niche.

G. S. Vida, S. Roberson, S. DiNardo; University of Pennsylvania, Philadelphia, PA.

Stem cells self-renew, and can also produce daughter cells that will differentiate into the specialized cell types that are important for function and repair of their resident tissue. Many tissues become compromised as they age, raising major questions about how stem cell behavior is affected during aging. Aging might affect factors intrinsic to stem cells, or extrinsic factors from their environment, since niches often influence decisions between self-renewal and differentiation. The *Drosophila melanogaster* testis is a well-studied tissue that has served as a paradigm for our understanding of communication between the stem cells and their niche. Niche signals maintain germline stem cells (GSCs) in several ways. One particular function acts to orient GSC divisions so that differentiating daughter cells move out of the influence of the niche, and therefore can eventually produce sperm. For this division to be oriented properly, the stem cell centrosome is anchored at the interface with the niche, and this relies on factors such as E-cadherin and Apc2 within stem cells (Yamashita et al, 2003; Inaba et al, 2010). Previous work in our lab showed that one signal secreted by the niche, Unpaired, maintains E-Cadherin-based adhesion of the GSC to the niche (Leatherman and DiNardo, 2010). Since others have shown that this signal decreases with age, we wished to test whether aging might reduce the fidelity of the oriented divisions (Toledano et al, 2012). We quantify oriented divisions using live imaging and other tools to extract the division axis in 3D space relative to the niche/stem cell interface (Jüschke et al, 2014). Preliminary data showed that in aged testes orientation was indeed compromised, as there was less of a bias towards division away from the niche. This suggests that the fidelity of oriented divisions has been compromised with age. Assessing such changes in stem cell dynamics upon aging will help us asses how stem cell-niche communication is disrupted with age, and will thus fill an important gap in our knowledge.

P703/B720

Bax Inhibitor-1 (bi-1) Regulates D-galactose-induced Cellular Senescence.

M. Chaudhary[1], K. R. Bhattarai[1], H. Kim[2], H. Chae[1]; [1]Chonbuk Nat'l University, Jeonju, KOREA, REPUBLIC OF, [2]Dankook University, Cheonan, KOREA, REPUBLIC OF.

ER stress is one of the critical features in senescence. Bax Inhibitor-1 (BI-1) is an evolutionary-conserved endoplasmic reticulum (ER) protein that regulates cellular response to ER stress and apoptosis.

However, the role of BI-1 in regulation of senescence remains elusive. In this study, we aim to assess whether BI-1, an ER stress regulator, participates in regulating drug-induced cellular senescence. Using D-galactose and tunicamycin as an aging and ER stress inducer respectively, we demonstrated and compared different ER stress markers in hepatic cell lines. Palmitate (250 μM), a saturated fatty acid was used to induce lipid-mediated ER stress. Senescence markers such as p53 and p21 as well as ER stress markers such as GRP78, CHOP, p-IRE1a, sXBP1, and p-eIF2a were analyzed by western blotting using various concentrations of D-galactose and palmitate. D-galactose treatment in Hep3B cells induces expression of p53, p21 and CHOP expression. Interestingly, combined treatment of D-gal and palmitate induced senescence as well as the expression of ER stress proteins. These experiments were conducted and compared in HA-tagged BI-1 overexpressed cells and with neomycin resistance pcDNA3 hepatic cells. We present evidence that senescence and ER stress-induced ROS was decreased in BI-1 overexpressed cells. The expression of ER stress response proteins such as GRP78, phosphorylation of IRE1α and eIF2α, spliced XBP1 and CHOP were analyzed and found that the BI-1 showed the inhibitory response of ER stress in D-gal, palmitate, tunicamycin or combined treated HepG2 and Hep3B cells. Moreover, D-gal, palmitate, tunicamycin, combined treatment of D-gal and palmitate, or with tunicamycin induced cleavage of caspase-7 and caspase 12 were also alleviated in BI-1 overexpressed cells, regulating ER stress-mediated apoptosis. Together, our findings revealed that BI-1 regulates and protects hepatic cells from senescence-mediated ER stress and suggests that activation of BI-1 has the potential to alleviate D-gal-induced senescence. **Keywords:** Bax Inhibitor-1, D-galactose, senescence, ER stress, apoptosis

P704/B721

Temporal Control of FOXO Expression Levels Alleviates Acute High Dose-induced Cardiac Dysfunction in Young and Aged *Drosophila*.

A. C. Blice-Baum, M. Khan, N. Rodriguez; Cabrini University, Radnor, PA.

Cardiovascular disease (CVD) is one of the leading causes of death worldwide, and the risk of developing it increases with age. *Drosophila melanogaster* is a rapidly aging animal model whose limited genetic variability and cellular complexity allows for comprehensive exploration of cardiac senescence within a short time frame relative to other standard model organisms. The transcription factor FOXO has been associated with longevity and health-span for some time and regulates expression of genes involved in many cellular processes. Previously, mild cardiac-restricted dFOXO overexpression in *Drosophila* provided cardioprotection accompanied by increased expression of genes associated with the ubiquitin-proteasome system (UPS) at advanced age. Increasing the dosage of dFOXO, however, proved lethal. As a transcription factor, FOXO must be activated in specific amounts for proper cellular function, but this activity is likely weakened over time, contributing to cellular senescence. This has not yet been shown explicitly in animal models or aged human samples. We hypothesized that overexpressing FOXO later in life would alleviate the negative effects observed in young flies and potentially improve heart function at advanced age. To test this hypothesis, we have used a GeneSwitch heart-specific GAL4 driver. Overexpressing moderate doses of dFOXO using mifepristone, RU486, beginning at week 3 resulted in unimpeded heart function. This is in contrast to previous results showing that even mild overexpression of dFOXO using RU486 at 2-days post-eclosion caused heart function decline in young flies. Furthermore, when these flies were aged to 6 weeks, elderly for a fruit fly, they experienced ameliorated cardiac decline compared to flies given vehicle.

P705/B722

Progerin Expression Causes Splicing Mis-regulation in Non-hgps Patients.

R. Yu; University of Maryland College Park, College Park, MD.

Hutchinson-Gilford progeria syndrome (HGPS) is a rare, autosomal dominant disorder caused by a mutation in the *LMNA* gene that activates a cryptic splice site whose use results in a mutant lamin a protein product known as progerin. Progerin interferes with lamin a protein function in a dominant negative manner and causes nuclear abnormalities, genomic instability, and altered redox homeostasis. Remarkably, progerin is also found in normally aging individuals. Progerin production appears to be induced by various types of DNA damage, including DNA double-strand breaks (DSBs) induced by telomere shortening or UV light. Furthermore, the preliminary analysis in hundreds of tissue samples from the Genotype-Tissue Expression Project (GTEx) reveals striking correlations between progerin expression and the expression of genes known to regulate RNA splicing. My studies seek to elucidate the causal relationships between DNA damage, altered splicing, progerin production, and downstream effects.

P706/B723

The Recovery Effect of Mitochondrial-derived Peptide Mots-c to Aged Human Placenta-derived Mesenchymal Stem Cells.

W. YU[1], Y. KIM[1], J. SEOK[1], G. KIM[1], J. GO[1], C. LEE[2], **J. Lee**[1,3]; [1]CHA University, Seoul, KOREA, REPUBLIC OF, [2]University of Southern California, USA, CA, [3]CHA Fertility Center Seoul station, Seoul, KOREA, REPUBLIC OF.

The aging of the mesenchymal stem cell (MSC) is one of the major reasons behind the cause of diseases such as the regeneration disorder, and it is related to metabolic homeostasis in the cells. However, recovery factors of aged MSC are not completely elucidated for the MSC. Loss of cellular function in aging is associated with metabolic homeostasis and oxidative stress such as the ROS production. Recently, the mitochondrial open reading frame of the 12S rRNA-c(MOTS-c) was reported to have played a role for the metabolic homeostasis activity. But specific effects of MOTS-c were not investigated for the recovery of aged the MSC for humans. Here we investigate the recovery of aged MSC with MOTS-c through metabolic homeostatic. We prepared and maintained human chorionic plate-derived mesenchymal stem cells (hCP-MSC) donated by our colleague. An d we made old passage hCP-MSC as aged cells by in *vitro* overpassing subculture from young hCP-MSC. Then we confirmed phenotypes of the aged hCP-MSC such as cellular morphology, doubling times and several senescence associated genes and proteins expression like AMPK, SIRTs, FOXO, HO-1/2 and SOD1/2. The activated form of AMPK by phosphorylation was also confirmed as AMPK is a major target of MOTS-c. As a result, aged MSCs exhibit a larger cell size compared to young MSCs. But MOTS-c treated aged MSCs decrease in cell size compared to aged MSCs. In addition, MOTS-c treated aged MSCs showed to appear as a more spindle-like shape like young hCP-MSC while aged MSCs showed a flatter and an abnormal cellular shape. Above these, aged hCP-MSC showed to significantly decrease in doubling-time and lipid droplet formation by MOTS-c. Therefore, aged MSCs that were treated with MOTS-c have significantly increased gene and protein expression level in senescence associated genes compared to the aged MSCs. It's mean cellular homeostasis was recovered as a young hCP-MSC from aged hCP-MSCs. Phosphorylated-AMPK was also evaluated and showed similar positive results as well. In conclusion, we found out that the rejuvenation effects of MOTS-c for aged MSCs was similar to the way that the genes associated with

cellular homeostasis and prevention of ROS damage act. Also, recovered cellular morphology and decreased doubling-time and lipid droplet formation also supported the rejuvenation effects of MOTS-c. Therefore, after further study, we want to apply to in vivo study for clinical application.

P707/B724

A Novel Regulator of Branched-chain Amino Acid Homeostasis Controls the Actin Cytoskeleton and Extends Lifespan in *Saccharomyces Cerevisiae.*

C. N. Sing, 10033[1], R. Higuchi-Sanabria[2], A. C. Coughlin[1], C. A. Tsang[1], E. J. Garcia[1], I. R. Boldogh[1], L. A. Pon[1]; [1]Columbia University, New York, NY, [2]University of California, Berkeley, Berkeley, CA.

Previous studies in our laboratory revealed that the membrane cytoskeletal interactions that support mitochondrial inheritance results in preferential inheritance of fitter mitochondria by yeast daughter cells, which promotes daughter cell fitness and lifespan. Specifically, we found that actin cables, bundles of actin filaments that align along the mother-bud axis and serve as tracks for movement of mitochondria from mother to daughter cells, are dynamic structures that move in the retrograde direction, from bud to mother cells. As a result, mitochondria are effectively “swimming upstream” against the opposing force of retrograde actin cable flow (RACF) as they move from mother to bud cells, thus, the bud cells’ preferentially inherit higher functioning mitochondria that are more motile and have a higher membrane potential. This, in turn, contributes to mother-daughter age asymmetry, the process whereby mother cells continue to age as they give rise to daughter cells that are, for the most part, born young and with a full replicative lifespan. Here, we report that the stabilization of actin cables can also promote mitochondrial fitness and extend replicative lifespan, and a role for a previously uncharacterized open reading frame (ORF) in that process. Using a genome-wide screen, we found that the deletion of an ORF reduced the sensitivity of yeast to growth inhibition induced by the actin destabilizing drug, Latrunculin-A (Lat-A). Yeast bearing a deletion in this gene also displayed an increase in actin cable abundance and stability, increased mitochondrial fitness, and extended lifespan. Transcriptome analysis revealed that deletion of this ORF results in decreased branched-chain amino acid (BCAA) biosynthesis and increased BCAA degradation. Consistent with this, we find the deletion of BCAA transaminase produces cells with increased actin cable abundance and mitochondria fitness, which are similar to those observed upon deleting the ORF. Furthermore, physically changing external BCAA levels also result in the same morphological changes in the actin cytoskeleton. Moreover, we find that the observed phenotypic changes occur in a TORC1-independent manner. Finally, we find that stabilizing actin promotes mitochondrial function and the fitness of yeast as they age. Our studies revealed a novel regulator of BCAA metabolism, and a role for BCAAs in the actin cytoskeleton regulation, which in turn, increases mitochondria quality and extends longevity. An alysis of this newly identified factor will not only expand our understanding of the interconnection between nutrients, the actin cytoskeleton and aging, but also provide a foundation for developing aging interventions.

Ubiquitin and Proteasome Function

Molecularly Distinct Cores Coexist Inside Stress Granules.

L. Cirillo, A. Cieren, **M. Gotta**; University of Geneva, Geneva, SWITZERLAND.

Stress granules are membraneless organelles that form in eukaryotic cells after stress exposure. Stress granules are constituted by a stable core and a dynamic shell that establishes a liquid-liquid phase separation with the surrounding cytosol. The structure and assembly of stress granules and how different components contribute to their formation are not fully understood. Here, using super resolution and expansion microscopy, we find that the stress granule component UBAP2L and the core protein G3BP1 occupy different domains inside stress granules. Since UBAP2L displays typical properties of a core protein, our results indicate that different cores coexist inside the same granule. Consistent with a role as a core protein, UBAP2L is required for stress granule assembly in several stress conditions and reverse genetics show that it acts upstream of G3BP1. We propose a model in which UBAP2L is an essential stress granule nucleator that facilitates G3BP1 core formation and stress granule assembly and growth.

P709/B726

Regulation of the Unfolded Protein Response during Er Stress.

T. Moretti[1], K. Kim[2], S. Park[1], J. Kim[1]; [1]Department of Biomedical Sciences, College of Veterinary Medicine, Iowa State University, Ames, IA, [2]Specific Organs Cancer Branch, National Cancer Center, Goyang, KOREA, REPUBLIC OF.

The endoplasmic reticulum (ER) coordinates critical cellular functions such as protein folding, Ca^{2+} storage and lipid and carbohydrate metabolism. Intrinsic and extrinsic processes can disturb protein folding homeostasis. The unfolded protein response (UPR) is the principal stress signaling pathway of the ER which is activated when the ER homeostasis is disturbed. The UPR is transduced via three sensors: pancreatic ER eukaryotic translation initiation factor (eiF)-2 α kinase (PERK), inositol-requiring enzyme 1 (IRE-1), and activating transcription factor 6 (ATF6). While studying the functions of cullin 3 (CUL3) we accidentally uncovered a new link between CUL3 and the UPR. Here, we propose CUL3 as a new regulator of the UPR sensors. CUL3 is the scaffold component of CUL3-RING ubiquitin ligases (CRL3s) where BTB proteins serve as substrate-specific adaptors. Knockdown of CUL3 in human skin fibroblasts resulted in increased levels of PERK and IRE1α, but not those of ATF6. Looking further downstream the pathway, increased levels of PERK led to enhanced phosphorylation of eIF2α, a downstream effector of PERK. When the ER of the fibroblasts was stressed with DTT, CUL3 knockdown resulted in an increase of spliced XBP1, a downstream effector of IRE1α. The UPR regulation, especially of the PERK branch, by CUL3 was also observed in other cell lines (IMR90, HeLa and C2C12). However, CUL3 did not regulate the levels of IRE1α in HeLa cells and C2C12 cells. These results suggest that CUL3 regulates the UPR in a cell line-specific manner. We identified that BTB proteins such as KLHL12 and KLHL41 regulate PERK levels in the fibroblasts and C2C12 myotubes, respectively. Our data indicate that the observed cell line-specific UPR regulation depends on the profile of relevant BTB proteins in a cell line. We conclude that CUL3 represents a new class of UPR regulators. Interestingly, KLHL41 mutations have been shown to cause nemaline myopathy. The mutations cause destabilization of the sarcomeric thin filaments. Diseased muscles also exhibit atrophy and regenerative defects. However, it is unclear

how the structural defects of the filaments influence survival and regeneration of muscle. As PERK has been implicated in muscle survival and regeneration, we propose that KLHL41 mutations disturb the UPR and this UPR dysregulation contributes to muscle atrophy and regenerative defects.

The Effects of *Ubc-6* Mutations on Glr-1 Abundance in *C. Elegans*.

J. Stair, H. Hulsey-Vincent, L. Dahlberg; Western Washington University, Bellingham, WA.

In order for proteins to function properly, they must fold into their correct structures. Some proteins may not be able to fold correctly and can adversely affect the health of an organism, as the accumulation of misfolded proteins has been associated with several neurodegenerative diseases. To prevent misfolded proteins from aggregating, a biochemical pathway called Endoplasmic Reticulum-Associated Degradation (ERAD) ensures that misfolded proteins are degraded. ERAD utilizes several different proteins that work together to attach the protein ubiquitin to the surfaces of misfolded proteins. UBC-6 is an E2 ubiquitin conjugating enzyme that helps attach ubiquitin to misfolded proteins and is encoded by the gene *ubc-6*. GLR-1 is an AMPA-type glutamate receptor known to be involved in learning and memory. To investigate the role of ERAD components and whether or not different mutations affect GLR-1 abundance, we performed immunoblotting analysis of animals expressing GLR-1 fused to GFP (GLR-1::GFP) in a variety of different mutant backgrounds. We quantified GLR-1 protein abundance in three *C. elegans* strains with different mutations in the *ubc-6* gene. The mutations included a single point mutation, a large knock-in/substitution, and a complete excision of the coding region. Our results show that there is no significant difference in GLR-1 abundance between wild type animals and those harboring any of the *ubc-6* mutations. This suggests GLR-1 abundance isn't regulated solely by *ubc-6* and there may be other compensatory mechanisms involved in its regulation. We are currently testing the effect of loss of function mutations in another E2 gene, *ubc-7* on GLR-1::GFP abundance. This research will help us determine the importance of ERAD in regulating GLR-1. Researching the ERAD pathway in *C. elegans* is exciting not only because most of the research on ERAD has been done in yeast, but it will also help us determine whether ERAD components function in a similar manner in yeast and worms.

P711/B728

The Enzyme Activity of Ubiquitin-specific Protease 8 Is Regulated by the Intramolecular Interaction of the USP Domain and the WW Domain.

K. Kakihara, K. Asamizu, A. Endo, A. Kato, M. Komada, T. Fukushima; Tokyo Institute of Technology, Kanagawa, JAPAN.

Ubiquitin-specific proteases (USPs) are a family of deubiquitinating enzymes. USP8, a member of USPs, deubiquitinates growth factor receptors at the endosome, enhances their recycling to the plasma membrane, and thereby plays a critical role in the control of cell proliferation. However, the regulatory mechanisms of USP8 activity are not fully understood. Here, we show a novel autoinhibitory mechanism of USP8 activity. Firstly, we measured deubiquitinating activities of wild type USP8 and the deletion mutants toward ubiquitin chains in *vitro*. A deletion of a central region (aa 645-684) increased the activity, indicating that this is an autoinhibitory region. Ubiquitin-vinyl methyl ester (Ub-VME) is a probe that can covalently bind to the USP catalytic site. The deletion of the autoinhibitory region increased the in *vitro* binding of USP8 to Ub-VME. Amino acid sequence of this autoinhibitory region is partly

homologous to the WW domains of MAGI-1 and SAV-1. Amino-acid substitution of conserved tryptophan to serine (W655S) increased the USP8 enzyme activity, indicating the importance of this residue. In general, WW domain interacts with proline-rich hydrophobic sequences. Substitutions of L954 and P955 in the USP domain to alanines (L954A;P955A) also increased the USP8 enzyme activity. It raised the possibility that the autoinhibitory region intramolecularly interacts with this hydrophobic sequence in the USP domain, thereby inhibiting the USP domain-ubiquitin interaction. To test it, we constructed a single molecule FRET probe in which YFP and CFP were fused to the autoinhibitory region and the USP domain, respectively. As expected, we observed FRET signal in lysates of HEK293T cells expressing this probe. W655S mutation decreased the FRET signal, and L954A;P955A mutation also decreased it. Taken together, these results indicate the region aa 645-684 in USP8 forms functional WW domain, intramolecularly interacts with the hydrophobic sequence containing L954 and P955 in the USP domain, and inhibits the enzymatic interaction between USP domain and ubiquitin chains. Our findings may provide a better understanding of the physiological regulation of USP8 activity and fine-tuning of growth factor signaling.

P712/B729

Investigating the Mechanism of Smurf2 Regulating DNA Damage Response.

L. Tang, A. Thomas, Y. E. Zhang; National Cancer Institute, Bethesda, MD.

Smad ubiquitin regulatory factor 2 (Smurf2) was originally discovered as an E3 ubiquitin ligase regulating the Smad-dependent TGF-β signaling pathway. Later on, Smurf2 was discovered to have a tumor suppressor role by targeting ring finger protein 20 (RNF20) for polyubiquitination and proteasome degradation. As RNF20 is also an E3 ligase which catalyzes the monoubiquitination of histone H2B and causes chromatin relaxation, the accumulation of RNF20 in Smurf2-/- MEFs makes the relaxed chromatin more susceptible to DNA damage, which can result in genomic instability and lead to tumorigenesis. Conversely, RNF20-H2B pathway plays a positive role in DNA damage response, where monoubiquitinated H2B recruits repairing proteins to the damage sites and facilitate the clearance of γ-H2AX, a marker of DNA damage. Smurf2 and RNF20 were found to be colocalized at the γ-H2AX foci of double-stranded DNA breaks in the nucleus, indicating that Smurf2 may also has a role in DNA damage response. As phosphorylation cascade plays an important role in regulating DNA damage response, we seek to examine Smurf2 phosphorylation upon etoposide treatment, which can induce DNA double-stranded break. Smurf2 was found to be an ATM substrate by the in-vitro kinase assay. The degradation of RNF20 by Smurf2 was triggered by etoposide treatment and blocked by an ATM inhibitor, which indicates that the phosphorylation is important for the ubiquitination process. Further we identified the phosphorylation site and made phosphorylation-block mutant. The phosphorylation mutant affected the binding between Smurf2 and RNF20, thus decreased the ubiquitination of RNF20 by Smurf2. Further, we treated Smurf2-/- MEFs stably expressing WT or mutant Smurf2 or control vector with etoposide, and we found that more cell death was observed in WT MEFs, which indicates that the phosphorylation may increase the sensitivity of the cells to etoposide treatment. In summary, we discovered that ATM-mediated Smurf2 phosphorylation is important for the ubiquitination of RNF20 by Smurf2 and Smurf2 plays a dual role in DNA damage response through degrading RNF20, by which Smurf2 makes chromatin more compact and then resistant to DNA damage while fewer repairing proteins are recruited when DNA damage happens.

P713/B730

The AUP1 UBE2G2 Binding Region (G2BR) Plays a Central Role in Activating Endoplasmic Reticulum-associated Degradation.

C. E. Smith, Y. Tsai, Y. Liang, J. Mariano, J. Li, S. G. Tarasov, D. Khago, R. A. Byrd, X. Ji, A. M. Weissman; National Cancer Institute, Frederick, MD.

The endoplasmic reticulum (ER) is the point of entry to the secretory pathway for nearly a third of newly-synthesized proteins. For this reason, ubiquitin and proteasome-mediated ER-associated degradation (ERAD), which regulates protein levels and effects quality control, is fundamental to proteostasis. In mammalian cells there are ~35 ubiquitin-conjugating enzymes (E2s) that functionally pair, in a highly selective manner, with >500 substrate-specific RING ubiquitin ligases (E3s) to mediate ubiquitination. Despite this E2:E3 selectivity in cells, in *vitro* assays demonstrate very limited selectivity in E2:E3 pairings. In ERAD, the most prominent E2 is UBE2G2. This cytoplasmic E2 has been shown to functionally interact in cells with multiple ERAD E3s, including gp78, HRD1 (Synoviolin), and TRC8. Yet, of greater than 30 potential ERAD E3s, only gp78 is known to directly recruit UBE2G2. This occurs via its UBE2G2 binding region ($G2BR^{gp78}$). Determining how UBE2G2, among all of the cytosolic E2s, is recruited to the ER to catalyze substrate ubiquitination with ERAD E3s, other than gp78, is critical to understanding proteostasis. An cient ubiquitous protein 1 (AUP1) is an ER membrane-anchored accessory protein that is required for ERAD mediated by HRD1 and TRC8, but not gp78. Strikingly, AUP1 includes a 26 amino acid cytosolic region that binds specifically to UBE2G2. This $G2BR^{AUP1}$ bears sequence similarity to $G2BR^{gp78}$. We have determined the structure of the $G2BR^{AUP1\ in}$ complex with UBE2G2. The $G2BR^{AUP1}$ forms an alpha-helix that interacts with the 'backside' of UBE2G2 via an extended interface that includes numerous electrostatic and hydrophobic contacts. An alogous to the $G2BR^{gp78}$, this interaction site is distant from both the active-site cysteine of the E2 and its canonical RING-binding interface. In *vitro*, the $G2BR^{AUP1}$ binds UBE2G2 with low nanomolar affinity, allosterically enhances UBE2G2:RING affinity, and stimulates RING-mediated ubiquitination. Although AUP1's acyltransferase and ubiquitin-binding CUE domains have been suggested to be important for ERAD, we find that a membrane-tethered $G2BR^{AUP1}$ is necessary and sufficient for degradation of multiple ERAD substrates in cells. Furthermore, we demonstrate that, in cells, the $G2BR^{AUP1}$ selectively recruits UBE2G2 to the ER membrane to target both HRD1 and TRC8 substrates. Importantly, however, membrane recruitment of UBE2G2 is not sufficient for ERAD. The $G2BR^{AUP1}$ is also required to activate this E2. Thus AUP1, through its G2BR, serves as an essential activator for multiple ERAD E3s, likely including some that await assessment, and is a key player in proteostasis.

P714/B731

Modeling Neurodegeneration in the Endoplasmic Reticulum-associated Protein Degradation Pathway Using *C. Elegans*.

N. Alvinez, R. Uhrich, L. Dahlberg; Western Washington University, Bellingham, WA.

Neurons are the cells that send and receive signals, allowing animals to perceive their environment and respond to their surroundings. Proteins are essential, complex molecules that carry out a wide variety of functions within a cell. The function of a protein is determined by its shape and how it is folded. When proteins are misfolded, they may lose their ability to function correctly, accumulate within a cell, and form protein aggregates that disrupt other processes. Therefore, the ability to degrade misfolded proteins is important for maintaining healthy cellular function. Without protein regulation, protein

aggregates in neurons may cause neurodegenerative diseases such as Parkinson's and Alzheimer's disease. Endoplasmic reticulum-associated degradation (ERAD) is a ubiquitin-dependent process that allows cells to eliminate misfolded proteins and prevent toxic protein aggregation at the Endoplasmic Reticulum (ER). Ubiquitin is a small protein that is attached to misfolded proteins to mark them for proteasomal degradation, via ERAD. UBC-6 and UBC-7 are E2 ubiquitin-conjugating enzymes that are important for ERAD in yeast, but there is much less known about they may work during ERAD in neurons. We use mutational analyses to understand how vital UBC-6 and UBC-7 are in regulating neurotransmitter receptors in the nematode worm, *C. elegans*. We used two types of mutations: point mutations and gene knockouts. We hypothesized that a gene knockout of *ubc-6* or *ubc-7* could cause an increase in protein aggregation when compared with single point mutations because a larger deletion may be more severe and has been associated with behavioral defects, while a point mutation might leave the enzyme still active. In order to track neural protein aggregation, we follow the glutamate receptor GLR-1 with a green fluorescent protein (GFP) tag (GLR-1::GFP) and utilize fluorescence microscopy and FIJI image analyzing software. We found that *ubc-7* knockout mutants had a significantly higher abundance of GLR-1::GFP in cells that express the fusion protein when compared to wild-type and the other mutations. Our findings suggest that our point mutation mutants and *ubc-6* mutants still carry out ERAD, though less efficiently than wild-type. Since the knockout mutations in UBC-7 resulted in increased protein aggregation when compared with UBC-6, this suggests that UBC-7 is more vital for ERAD than UBC-6 in regulating neurotransmitter receptors. In the future, we will be creating fluorescent reporters for UBC-6 and UBC-7 to assess their expression and localization; we will also analyze GLR-1::GFP abundance for the *ubc-6* and *ubc-7* double mutants.

Inflammatory Bowel Disease-associated Ubiquitin Ligase RNF183 Promotes Lysosomal Degradation of DR5 and TRAIL-induced Caspase Activation.

Y. WU, **T. Okamoto**, K. Imaizumi, M. Kaneko; Department of Biochemistry, Graduate School of Biomedical and Health Sciences, Hiroshima University, Hiroshima, JAPAN.

Ubiquitin ligase (E3) is the most critical enzyme in the ubiquitination machinery for forming polyubiquitin chains as it participates in the regulation of substrate preference and degradation rate. It has recently been reported that RNF183 expression is upregulated in intestinal epithelial cells in inflammatory bowel disease (IBD) patients and in trinitrobenzene sulfonic acid-induced colitis mice. However, the molecular mechanisms of RNF183 in the development and pathophysiology of IBD are not fully understood. Here, we used 3.5% dextran sulfate sodium (DSS) in the drinking water for 1, 3, and 5 days to establish an acute colitis model. The levels of RNF183 expression and inflammation were evaluated by quantitative PCR in terms of changes in inflammatory marker levels and by hematoxylin-eosin staining, respectively. PCR analysis revealed that RNF183 mRNA levels were significantly upregulated in DSS-induced colitis mice at 1 and 3 days after exposure and were most highly upregulated at 5 days. Although the levels of inflammatory markers, such as IL-1& beta and TNF-& alpha, also significantly increased at 5 days after exposure, their levels were not significantly changed at 1 day after exposure. From this, we speculate that RNF183 was not upregulated as a downstream target of the inflammatory response. Furthermore, we identified death receptor 5 (DR5) as a substrate of RNF183 using shotgun proteomic analysis. DR5 is known as a cell surface receptor of the TNF-receptor superfamily and it promotes TNF-related apoptosis inducing ligand (TRAIL)-induced apoptosis signal through interaction with caspase-8. We showed that RNF183 induced degradation of DR5 in the

lysosome through K63-linked ubiquitination. We also identified that RNF183 promoted TRAIL-induced activation of caspase-3 and caspase-8 through ubiquitination of DR5. Thus, RNF183 promoted not only DR5 transport to lysosomes but also TRAIL-induced caspase activation. Taken together, our findings suggest that RNF183 may play important roles in the onset and/or exacerbation of DSS-induced colitis and IBD through DR5 degradation.

P716/B733

Quantitative an alysis of the UPS Reveals Productive Adaptive Responses to Both Proteasomal and Protein Folding Stressors.

J. Work, O. Brandman; Stanford University, Stanford, CA.

Failures in the ubiquitin-proteasome system (UPS) are associated with challenges such as aging, disease-causing mutations, and environmental conditions. Yet a quantitative understanding of how the UPS responds to stress conditions is lacking. Here we characterized the performance and adaptability of the UPS in yeast using quantitative measurements of UPS performance (the ability to degrade misfolded substrates) and adaptation (transcriptional regulation of UPS components via the stress-sensing gene, RPN4). We observed multiple adaptive regimes, including perfect adaptation driven by two independent mechanisms: stabilization of the normally degraded Rpn4 protein under proteasomal stress and increased transcriptional of RPN4 under protein folding stress. Critically, we found that degradation-based regulation of Rpn4 is insufficient for UPS adaptation because protein folding stressors caused misfolded proteins to aggregate rather than become targeted to the proteasome and outcompete Rpn4 for degradation. Our work suggests the yeast proteasome evolved to favor aggregation of misfolded proteins over their degradation and reveals the versatility of cells in productively adapting to proteotoxic stress.

P717/B734

Novel Approaches to Protac Drug Discovery.

D. Ouazia, 19355, K. Kadimisetty, 19355, H. O'Malley, 19355; LifeSensors, Inc., Malvern, PA.

Proteolysis targeting chimeras (PROTAC) is a very promising strategy to ubiquitylate and degrade target proteins, especially undruggable targets. Despite initial euphoria over this novel approach to knock down a protein function, meaningful progress has not been made. Nearly all the companies working to develop PROTAC drugs are focused on known ligases, such as cereblon, VHL or HDM ligases as vehicles. This approach may be flawed, however, in that nature does not employ the “one ligase fits all” target approach. In addition, major hurdles hinder current screening approaches, which include western blotting to monitor degradation of protein bands or reporter-based cellular assays such as that developed by Promega. These methods require multiple steps and are time-consuming, irreproducible, subject to human error, and not amenable to high throughput screening. Cell reporter assays require the generation of stable cell lines and are prone to artifacts. Moreover, current PROTAC screens do not provide any information regarding the poly-ubiquitination state of the target protein, a modification required for degradation. These problems have frustrated medicinal chemists and biochemists alike. We have developed a high-throughput microtiter plate-based approach, the UbiQuant Ultra, that evaluates protein ubiquitination, a true measure of a PROTAC molecule under physiological conditions. We have demonstrated the efficiency of a bromodomain PROTAC and a promiscuous kinase inhibitor that subsequently degrade their corresponding target proteins. We have established poly-ubiquitination and

degradation of BRD3 in response to bromodomain PROTAC in a microplate environment. These data correlate directly with gel-based analysis of PROTACs, and the method itself rapidly provides reproducible data, requires less tissue sample, and is easily translated to a plate-based environment, thereby remarkably enhancing PROTAC drug discovery. The application of unique affinity matrices -- our tandem ubiquitin binding entities (TUBE)-based mass spec proteomics platform -- allowed us to confirm the selectivity and degradation status of the target proteins in response to treatment with various PROTACs. For the first time, one can determine if a PROTAC ubiquitinates a target protein without degrading it, thus allowing chemists to design selective PROTACs. The goal of this study is to implement efficient methods to analyze PROTAC functions in a high-throughput fashion and accelerate development of novel PROTAC drugs.

P718/B735

Two Alternative Mechanisms Regulate the Onset of Chaperone-mediated Assembly of the Proteasomal Atpases.

S. Park, A. Nahar, J. Orth, 80301; University of Colorado Boulder, Boulder, CO.

The proteasome holoenzyme is a molecular machine that degrades most proteins in eukaryotes. In the holoenzyme, its heterohexameric ATPase injects protein substrates into the proteolytic core particle, where degradation occurs. The heterohexameric ATPase, referred to as 'Rpt ring', assembles through six ATPase subunits (Rpt1-Rpt6) individually binding to specific chaperones (Rpn14, Nas6, Nas2 and Hsm3). Here, our findings suggest that the onset of Rpt ring assembly can be regulated by two alternative mechanisms. Excess Rpt subunits relative to their chaperones are sequestered into multiple puncta specifically during early-stage Rpt ring assembly. Sequestration occurs during stressed conditions, for example heat, which transcriptionally induce Rpt subunits. When the free Rpt pool is limited experimentally, Rpt subunits are competent for proteasome assembly even without their cognate chaperones. These data suggest that sequestration may regulate amounts of individual Rpt subunits relative to their chaperones, allowing for proper onset of Rpt ring assembly. Indeed, Rpt subunits in the puncta can later resume their assembly into the proteasome. Intriguingly, when proteasome assembly resumes in stressed cells or is ongoing in unstressed cells, excess Rpt subunits are recognized by an alternative mechanism—degradation by the proteasome holoenzyme itself. Rpt subunits undergo proteasome assembly until the holoenzyme complex is generated at a sufficient level. The fully-formed holoenzyme can then degrade any remaining excess Rpt subunits, thereby regulating its own Rpt ring assembly. These two alternative mechanisms, degradation and sequestration of Rpt subunits, may help control the onset of chaperone-mediated Rpt ring assembly, thereby promoting proper proteasome holoenzyme formation.

P719/B736

The Cdc48 Complex Alleviates the Cytotoxicity of Misfolded Proteins by Regulating Ubiquitin Homeostasis.

R. Higgins, M. Kibbaj, A. Hatcher, R. J. Tomko, **Y. Wang**; Florida State University, Tallahassee, FL.

Failure to destroy misfolded proteins is associated with cytotoxicity and is a hallmark of multiple neurodegenerative disorders. The mechanism(s) by which accumulation of misfolded proteins causes cytotoxicity remains poorly defined. Here, we demonstrate that the Cdc48/p97 segregase machinery drives clearance of the ubiquitinated model misfolded protein Huntingtin (Htt103QP) and limits its

aggregation. We show that the nuclear ubiquitin ligase San1 involved in protein quality control acts upstream of Cdc48 to ubiquitinate Htt103QP. Unexpectedly, we find that deletion of *SAN1* and/or its cytosolic counterpart, *UBR1*, rescues the toxicity associated with Cdc48 deficiency, raising the possibility that ubiquitin depletion, rather than compromised proteolysis, was responsible for the growth defect caused by Cdc48 deficiency. Indeed, Cdc48 deficiency leads to elevated protein ubiquitination but decreased free ubiquitin, which depends on San1 and Ubr1. We further show that enhancing free ubiquitin levels rescues the toxicity in various Cdc48 pathway mutants, and restores normal turnover of a known Cdc48-independent substrate. Our work highlights a previously unappreciated function for Cdc48 in ensuring the regeneration of monoubiquitin that is critical for normal cellular function.

P720/B737

Broad Inhibition of Deubiquitinases Unmasks Functional Redundancy Revealing Novel Proteasome Substrates and Enabling Specificity Profiling of These Enzymes.

V. Rossio[1], J. Paulo[1], J. Chick[1], B. Brasher[2], S. Gygi[1], R. W. King[1]; [1]harvard medical school cell biology, Boston, MA, [2]Boston Biochem, Boston, MA.

Deubiquitinating enzymes (DUBs) counteract substrate ubiquitination, affecting stability, activity or localization of the ubiquitinated proteins. The human genome encodes approximately 100 DUBs and most have no known substrates. Identifying DUB substrates and assigning specific biological functions to a DUB is challenging due to the fact that DUBs may act redundantly. Here, we circumvented the effects of redundancy by broadly inhibiting deubiquitination. We used quantitative mass spectrometry to identify proteins that are destabilized by broad DUB inhibition in *Xenopus* egg extract, and recapitulated this behavior with recombinant human proteins, demonstrating that their DUB-dependent stability is evolutionarily conserved. The majority of these proteins have not been reported previously as DUB substrates, even though some have been well-studied, such as the tumor suppressor Ing2, the Ewing tumor-associated antigen 1 (Etaa1) and the ubiquitin ligase Mkrn1 that targets p53. With a panel of novel substrates in hand, we tested the ability of individual DUBs to rescue degradation of these proteins. This approach revealed that USP7 has a broad ability to rescue these substrates from degradation. However, specific inhibition of USP7 was not sufficient to induce substrate instability, suggesting that DUBs function redundantly to control the stability of these proteins. Together, we present a new approach to identify DUB substrates and a system to characterize DUB specificity, overcoming the challenges posed by redundant action of DUBs.

Interactions between E3 Ubiquitin Ligases and Deubiquitylases - an Emerging Feature of Cellular Ubiquitin Dynamics.

J. MacGurn, 37240-7935, C. Nielsen; Vanderbilt University, Nashville, TN.

NEDD4 family E3 ubiquitin ligases, which are dysregulated in various human diseases, have been implicated as regulators of many membrane trafficking events in human cells, yet the mechanisms of substrate targeting and regulation remain poorly understood. We have identified specific deubiquitylating enzymes (DUBs) that interact physically with NEDD4 family E3 ligases to regulate specific ubiquitylation outcomes. Here, we describe recent experiments interrogating the regulatory functions of these E3-DUB interactions. We describe an E3-DUB interaction that governs a ubiquitin rheostat on a critical signal transducing protein in the WNT pathway. This rheostat influences toggling

between canonical and non-canonical states, thus impacting cellular behavior and response to environmental cues. These results underscore the dichotomous roles DUBs may play in the context of human cancer progression and have important implications for selection of DUBs as potential therapeutic targets.

Intracellular Regulation of Ate1 Isoforms.

L. V. Bonnet[1], J. B. Flores-Martin[1], A. Palandri[1], A. Kashina[2], M. E. Hallak[1]; [1]Centro de Investigaciones en Química Biológica de Córdoba, Córdoba, ARGENTINA, [2]Department of Biomedical Sciences, Philadelphia, PA.

Arginyltransferase (Ate1) mediates posttranslational protein arginylation and plays key roles in multiple physiological processes, including cardiovascular development, cell migration, and cytoskeletal organization. This enzyme is represented in mammalian cells by four alternatively spliced isoforms, expressed from a single gene and previously proposed to play different roles in vivo. The molecular distinctions between Ate1 isoforms are not well understood. Moreover, very little is known about the regulation of Ate1 in cells. Here we investigate intracellular Ate1 regulation by examining its isoform-specific compartmentalization and metabolic fate. Our results suggest that Ate1 isoforms have different intracellular localization and appear to shuttle between the cytoplasm and the nucleus. Cell treatment with proteasome inhibitor MG132 leads to isoform-specific changes in Ate1 intracellular levels and distribution, and its accumulation as perinuclear aggregates. Further analysis suggests possible Ate1 regulation by ubiquitinylation and other post-translational modifications that may modulate its reversible association with different intracellular compartments. Our results provide new insights into the molecular differences that underlie the differential function of Ate1 isoforms.

Using Resistance an alysis to Develop Chemical Probes for the AAA Protein Katanin.

N. H. Jones, T. Cupido, R. Pisa, T. M. Kapoor; the Rockefeller University, New York, NY.

Achieving selectivity for a single protein within a family presents a major barrier to chemical probe design. We are developing an approach, Resistance an alysis During Design (RADD), for revealing key interactions with target proteins and guiding the design of selective probes. RADD involves identification of non-conserved residues in an active site (“variability hot-spots”) and mutation of these residues in the target protein to those found in other members of the protein family. An alysis of compound activity against the resulting mutant alleles informs on small molecule binding poses. However, our analysis has thus far been limited to one protein from the AAA (ATPases associated with diverse cellular activities) family and two chemical scaffolds. Here, we describe application of RADD to katanin, a microtubule-severing AAA protein proposed to regulate microtubules in spindles and cilia. We find that mutating katanin at its variability hot-spot residues (Leucine-214, Threonine-253, Alanine-419, and Threonine-422) does not abolish nucleotide binding or ATP hydrolysis activity. Testing a heterocycle-based small molecule that inhibits katanin at low micromolar concentrations against these mutant alleles indicates active site residues that interact with the inhibitor. These data guided the design of compounds with

~10-fold improvements in potency over the parent compound. Our results suggest the broader utility of RADD as an inhibitor design approach. Mutations characterized in this in vitro work could also be used for conferring resistance to the inhibitor in cellular studies. Katanin-specific phenotypes are identified as those modulated by inhibition of the wild-type protein, but not the mutant protein.

Metabolic Toxicity of Vespa Amino Acid Mixture and Other Amino Acid Mixtures in *Artemia Salina*.

S. B. Redmond; Radford University, Radford, VA.

Vespa amino acid mixture (VAAM) is a solution of free amino acids secreted by larval Asian giant hornets - VAAM and similar solutions produced by other vespid species are thought to augment respiratory capacity. Previous work has shown increased ATP production is accompanied by destabilization of the inner mitochondrial membrane in mitochondrial isolates, cultured cells, and primary cell isolates of a variety of species. To evaluate the relationship between the specific amino acid profile of VAAM and mitochondrial metabolism, *Artemia salina* nauplii were assayed for ATP production, reactive oxygen species (ROS) production, and viability under serially diluted VAAM over a period of 24 hours. A mixture of amino acids replicating the hemolymph free amino acid composition of *A. salina* (HC) and a suspension of proline alone were used at matching concentrations as controls. Nauplii treated with 0.05% VAAM (or higher concentrations) showed a ≥ 53% decrease in viability after 24 hours relative to non-treated controls, while HC and proline treatments showed 10% and 6% reductions, respectively. ATP levels peaked at 1 hour for VAAM treated groups (2.5x control), while HC peaked at 12 hours (1.2x control) and proline at 24 hours (1.3x control). ROS production was negligible in non-VAAM treated groups, and peaked at 2 hours under VAAM treatment. Taken together, these data suggest that the mixture of amino acids in VAAM has a distinct interaction with cellular chemistry to influence mitochondrial function, and that the augmentation of aerobic respiration is not a result of increased reactant concentration.

P725/B743

Rational design of a chemically inducible t*rimerizaton s*ystem.

D. Wu[1], O. Dagliyan[2], N. V. Dokholyan[3], T. Inoue[1]; [1]Johns Hopkins University, Baltimore, MD, [2]Harvard Medical School, Boston, MA, [3]The Pennsylvania State University, State College, PA.

In response to environmental cues many cell signaling events occur rapidly on the order of seconds to minutes. Chemically inducible dimerization (CID) strategies such as the FKBP - FRB system can heterodimerize proteins of interest (POIs) inside cells at a similar timescale upon addition of small molecule drug rapamycin. CID is commonly used to translocate POIs towards or away from desired subcellular locations by using protein localization tags and can elucidate local protein function or synthetically actuate or perturb a downstream event. Other similar systems using chemical or light stimulation also cause dimerization or homo-oligomerization. However, no inducible trimerization system has ever been developed. We engineered a rapamycin-dependent system which we term chemically inducible trimerization (CIT). To our knowledge, this is the first such system which brings together three distinct proteins, perhaps because a trivalent chemical approach confers an extra degree of freedom and is thus challenging. With computational aid, we rationally designed split sites for FKBP and FRB. Positive split sites were identified by ability of plasma membrane (PM)-localized split FRB

(sFRB) and FKBP (sFKBP) pairs to recruit FKBP or FRB respectively upon rapamycin administration. Trimerization still occurred when sFRB or sFKBP were localized to different places in the cell, indicating that proximity is not a limiting factor in split pair reconstitution. In-cell kinetics of FKBP recruitment by an sFRB pair was determined, with exponential recruitment rate coefficient of -0.055 ± 0.01 1/s compared to full length FRB at -0.076 ± 0.01 1/s. Using CIT, cytosolic proteins could be conditionally targeted to inter-organelle membrane contact sites such as ER-PM and ER-mitochondria junctions. ER-PM junctions can be sites of lipid transfer and metabolism, which includes the regulation of $PI(4,5)P_2$ (or PIP2). While translocation of phosphatases or kinases to the ER or PM is possible with CID to perturb PIP2 levels, translocation contingent upon both ER and PM presence has not been achieved. Using CIT, we recruited PIP2 phosphatase INP54P to ER-PM junctions and locally depleted PIP2 at these sites - far beyond recruitment of FKBP alone or phosphatase-dead versions. This suggests that CIT can be used as a general paradigm to perturb ER-PM and other junctions. Altogether, we combined concepts of inducible dimerization and rational protein splitting to generate an inducible hetero-trimerization system, which can be useful for probing biological questions requiring three signals.

Bioorthogonal Smart Probe for Fluorescent Imaging of Carbonyl Moieties in Live Cells.

H. Erkan[1], D. Telci[1], **O. Dilek**[2]; [1]Yeditepe University, Department of Biotechnology, Istanbul, TURKEY, [2]University of Saint Joseph, Department of Chemistry, West Hartford, CT.

In recent years, bioorthogonal chemistry has found significant use in medical sciences. Controlling stable chemical reactions in biological systems by using bioorthogonal chemistry is not only one of the powerful tools but also the most challenging method, which has been widely performed with synthetic chemical probes to tag biomolecules in live cells. Site-selectively tagging and controlling biomolecules with suitable probes inside cells has the potential to manage challenges faced in clinical practice for early diagnosis and treatment of tumors. Herein, we designed a hydrazine based small molecule, which incorporates with the carbonyl moiety of biomolecules through click reaction to form a fluorescent hydrazone product, therefore can be utilized for the detection of biomolecule carbonylation in various cancer cell lines. Our almost non-fluorescent chemical probe can make fast covalent binding with carbonyl moieties at neutral pH to form a stable product leading to a red shift on the absorption maximum and an increase on the fluorescence quantum yield. Microscopic and fluorometric analyses were used to distinguish the exogenous and endogenous ROS induced carbonylation profile in human dermal fibroblasts along with A498 primary site and ACHN metastatic site renal cell carcinoma (RRC) cell lines. Confocal image analysis, UV-vis and spectrofluorometric measurements were also performed to detect and characterize the bioorthogonal coupling reactions. Our results showed that carbonylation level that differs in response to exogenous and endogenous stress in healthy and cancer cells, can be monitored by the newly synthesized chemical probe. When cells were exogenously ROS induced, A498 cell line demonstrated higher carbonylation level than the ACHN cells. Our results will therefore expand the applications of novel smart probes that are expected to enable deeper and more selective studies of cellular systems to enhance new diagnostic approaches in cancer.

P727/B745

Imaging Neuron Activity-dependent Compartment-specific Redox Dynamics.

S. Radhakrishnan, J. Norley, N. Leroy, M. Tantama; Purdue University, West Lafayette, IN.

Reactive oxygen species (ROS) are integral components of redox signaling in cells and mediate physiologically essential signaling across compartments. Under pathological conditions, excessive presence of ROS can lead to oxidative stress that damages cellular components and leads to cellular dysfunction and death. To understand dynamic redox changes and identify the mechanisms that disrupt redox homeostasis, we need high-precision tools that can be used to define redox processes in live cells under physiological and pathophysiological conditions. Genetically encoded fluorescent sensors that measure cellular redox status can be targeted to specific subcellular compartments to study the redox changes in intracellular compartments during live-cell imaging. However, it has remained technically challenging to quantitatively correlate spatially distinct redox dynamics with subcellular resolution. To address this challenge, we developed red fluorescent redox sensors that can be multiplexed with reduction-oxidation-sensitive green fluorescent proteins (roGFP) to image dual compartments within the same cell. Our approach utilized Förster-type resonance energy transfer (FRET) in a spectral relay strategy that extends the fluorescence emission of roGFP into red emission wavelengths We targeted the redox sensors to mitochondria and cytosol in primary hippocampal neurons and monitored sensor response to oxidizing and reducing agents. Upon neuronal stimulation of the neurons with glutamate, we observed an increase in mitochondrial oxidation accompanied by a cytosolic reduction. Pre-treatment with antioxidants MitoTEMPO and N-Acetyl Cysteine attenuated both the neuron-activity dependent cytosolic reduction and mitochondrial oxidation implying that these redox changes were coupled. In a mixed culture system, astrocytes are known to have a neuroprotective effect from oxidative insults and glutamate excitotoxicity. We targeted the redox sensors in a neuron-astrocyte co-culture system to observe the neuroprotective effect of astrocytes on neuronal redox dynamics. Using this sensor in combination with the roGFP, we can conduct live-cell imaging with spatio-temporal accuracy to delineate sub-cellular changes in redox dynamics that result in pathological oxidative stress.

P728/B746

The Effect of the Antioxidant Ascorbic Acid on the Energy of Activation of Free Radical Inhibition.

A. Wyandt, C. Saladino; Misericordia University, Dallas, PA.

It is widely accepted that free radical damage is involved in the development of numerous human pathologies, such as Alzheimer's and Parkinson's diseases, atherosclerosis, and some cancers. Thus, we previously developed a chemical model system utilizing a hydrogen peroxide-initiated luminol reaction to evaluate the efficacy of antioxidants to inhibit free radical-induced chemiluminescence. This chemiluminescence is proportional to the number of diradical intermediates produced in the reaction sequence. Thus, the purpose of the present study is to utilize this chemical model system to evaluate the effect of the antioxidant ascorbic acid on the energy of activation of free radical production. All reactions were run in at least duplicate or triplicate at pH 7.2 using a sodium phosphate buffer. First, a dose response for the inhibition of chemiluminescence was demonstrated utilizing ascorbic acid at concentrations of 0, 21, 42, and 85 µM, respectively. Then, a dose response was established for the inhibition of chemiluminescence by ascorbic acid at temperatures of 23, 30, 37, and 42 ^{o}C, respectively, for the baseline luminol reaction. In these reactions no ascorbic acid was present. This was followed by a series of luminol reactions run at each of these temperatures, respectively, for concentrations of

ascorbic acid of 0, 42, and 85 µM, respectively. From these luminometry data, the respective rate constants were determined, so as to allow an Arrhenius plot for the luminol reactions run with 0, 42, and 85 µM ascorbic acid, respectively. Thus, it was determined that in the absence of ascorbic acid, the energy of activation for the luminol reaction was 39.9 joules/mole, whereas the energy of activation was 131.14 joules/mole with 42 µM ascorbic acid and 168.94 joules/mole when the concentration of ascorbic acid was increased to 85 µM in the reaction system. Thus, as expected, the data clearly show that as the temperature of the luminol reactions was increased, both the rate and extent of reaction product increased for each of the above reaction series. However, these data also clearly demonstrate that the antioxidant ascorbic acid increases the energy of activation of the free radical-producing reactions they inhibit. This provides additional insight into the mechanisms by which antioxidants inhibit free radicals, and suggests that it is likely a similar result would be obtained with other antioxidants, such as NADPH, glutathione, and resveratrol. Current experiments are underway to test this hypothesis. Finally, the manner in which these experiments are designed could certainly provide an efficacious model that could be adapted into a number of informative and unique biochemistry/cell biology laboratory exercises.

Highly Selective in *Vivo* Editing of Macrophages through Systemic Delivery of Crispr Cas9-Ribonucleoprotein-nanoparticle Nanoassemblies.

V. Clark, Y. Lee, D. Luther, V. M. Rotello; UMass Amherst, Amherst, MA.

Gene editing of macrophages is a promising therapeutic strategy due to their role in host defense systems. Administration of protein-based CRISPR therapeutics in vivo is challenging due to proteolysis and endosomal entrapment. Previous work in our lab has demonstrated supramolecular nanoparticle-protein delivery assemblies for direct intracellular delivery, of recombinant CRISPR/Cas9 machinery. We hypothesized that systemic introduction of these nanoassemblies would provide efficient gene editing in *vivo* as well. Intravenous administration of CRISPR/Cas9 nanoassemblies into mice achieved specific localization and effective gene editing in macrophages. Through this approach, >8% gene editing efficiency specifically in macrophages of the liver and spleen was observed, with no detectable off-target editing. These systems allow the capability to engineer phagocytes *ex vivo* and in *vivo*, and thus could be an effective and very appealing approach to the development of immunotherapeutics (Ray, et al. 2018).

P730/B748

Sequence Determinants in the Allosteric Control of Camp Receptor Protein.

S. Dokas[1], L. Good[1], K. Taylor[1], V. Castro Fernandez[2], P. Cea Medina[2], V. Guixe[2], R. Maillard[1]; [1]Georgetown University, Washington, DC, [2]Universidad de Chile, Santiago, CHILE.

In this study, we aim to define the biophysical principles by which two functionally and structurally conserved proteins are allosterically activated differently, and how the results challenge the “structure-function” paradigm. The homodimeric cAMP Receptor Protein (CRP) is a bacterial transcription factor that is allosterically activated by cAMP. The cAMP-bound conformations of CRP from *Escherichia coli* ($CRP_{E.coli}$) and from *Mycobacterium tuberculosis* (CRP_{MTB}) are nearly identical, but their unbound conformations display significant differences, indicating that the allosteric regulation of these homologs do not follow the same mechanism. Previous studies of $CRP_{E.coli}$ have shown that interdomain communication across the dimer interface or between cAMP- and DNA-binding domains are critical to

$CRP_{E.coli}$'s function and allosteric regulation. However, the allosteric activation mechanisms of CRP_{MTB} are less known. To understand the importance of individual residues in the allosteric regulation of CRP_{MTB}, we made five single-point mutants based on well-characterized mutations in $CRP_{E.\ coli}$ that have been shown to modulate cAMP and DNA binding affinities. All the mutations were found to have comparable thermodynamic stability and secondary structure compared to wild-type CRP_{MTB}. However, cAMP and DNA binding assays show that mutational effects in $CRP_{E.\ coli}$ are non-translatable to CRP_{MTB}, indicating that single residues alone may not be the determining factor of allosteric communication. In addition to single mutants, we use ancestral reconstruction of CRP family members to introduce a collection of mutations to the protein. We find that the ancestral $CRP_{E.\ coli}$ and the ancestral CRP_{MTB} display similar folding and cAMP binding characteristics to their respective extant proteins. This may suggest that multiple amino acid residues are responsible for specific allosteric behavior, and that allosteric mechanisms cannot be tuned alone through single-site mutations. A common ancestor of both proteins will reveal the conserved motifs that give rise to the observed differences in allosteric regulation of CRP between *E. coli and MTB.*

Reactive Oxygen Species Generation in Plant Protoplast Triggered by Herbivore Oral Secretions.

A. Gandhi[1], C. Chapa[2], R. Kariyat[1], **N. Sahoo**[1]; [1]Department of Biology, University of Texas Rio Grande Valley, EDINBURG, TX, [2]Department of Biology, Mathematics and Science Academy, University of Texas Rio Grande Valley, EDINBURG, TX.

Plants are under constant attack by a suite of herbivorous insects and consequently, they have evolved a wide range of counter-defense strategies to either manage or resist them. These include physical structural defenses such as trichomes and spines and chemical defenses such as toxic secondary metabolites. Plant-herbivore interactions mediated signaling are generally initiated at the plant protoplast membrane, where herbivores physically damage the plant. Herbivore oral secretions (OS) trigger a series of signaling cascades that eventually lead to the mounting of various plant defense mechanisms. Reactive Oxygen Species (ROS) is a signaling molecule that has been known to play a role in activating plant defense cascade at the cellular level. While behavioral and mechanistic layers of such interactions have been well understood, the physiological link between the plant ROS production and herbivory is less understood. Here, we evaluated the effect of herbivore tobacco hornworm caterpillar (*Manduca sexta*) OS on the ROS level in isolated tomato (*Solanum lycopersicum*) protoplasts. Using the dye-based ROS imaging technique, we found that the Plant-Fed (PF)-*Manduca* OS triggered ROS production while artificial Diet-Fed (DF)-*Manduca* OS failed to induce ROS in tomato protoplasts. The addition of antioxidant NAC (N-acetyl-L-cysteine) antagonized the PF-*Manduca* OS induced ROS generation. Interestingly, Ca^{2+} chelator BAPTA-AM attenuated ROS induction by PF-*Manduca* OS, suggesting possible crosstalk between Ca^{2+} and ROS signaling. Taken together, our findings indicate that herbivores OS can directly modulate cellular ROS production and possibly regulate defenses against insect herbivores.

Role of an ionic Polypeptides in Lysozyme Phase Separation.

I. A. Antifeeva[1], A. V. Fonin[1], M. M. Karasev[2], I. M. Kuznetsova[1], K. K. Turoverov[1,3]; [1]Institute of Cytology of the Russian Academy of Science, St-Petersburg, RUSSIAN FEDERATION, [2]University of Helsinki, Helsinki, FINLAND, [3]Peter the Great St. Petersburg Polytechnic University, St-Petersburg, RUSSIAN FEDERATION.

Membrane-less organelles formed via liquid-liquid phase separation of biopolymers plays an important role in spatial organization of cytoplasm and nucleoplasm. Most of the cellular condensates are highly enriched with proteins containing intrinsically disordered regions. This is related to the fact that the flexible intrinsically disordered regions can easily form multivalent interactions with other chains with consequent phase separation. Conversely, it is believed that membrane-less organelles assembly by structured proteins is uncommon due to the high concentrations required for phase separation of such proteins. We suggest that the presence of highly oppositely charged disordered polypeptides which is wide-spread in proteome may reduce the threshold concentration of ordered proteins phase separation making it a general phenomenon in cells. In the present work pH dependence of the effect of anionic polypeptides on phase separation of the basic ordered protein lysozyme was studied. Poly-glutamic acid with polymerization degree 50 and intrinsically disordered protein prothymosin α, containing >30 % of negatively charged amino acids were used as anionic polypeptides. Concentration of polyanions and lysozime was 0.2 mg/ml 5 mg/ml, respectively. Using static light scattering measurements, we showed that at 2.5 < pH < 6.5 and 8.0 < pH < 10.4 homogeneity of lysozyme solutions was disturbed by injection of both polyanions. Examination of the turbid solutions using differential interference contrast microscopy showed that with the exception of macromolecular associates assembled at pH 5.0, all formed aggregates were amorphous. At pH 5.0 mixing of lysozyme with prothymosin α or poly-glutamic acid results in liquid-liquid phase separation and crystal formation respectively. Presumably, the more efficient screening of positively charged surface clusters of lysozyme by poly-glutamic acid leads to protein dehydration and drive the complex directly to solid crystals formation. Interestingly, the presence of poly-glutamic acid reduces the lysozyme concentration required for crystallization by at least factor four. Such effective salting out of ordered proteins by oppositely charged polypeptides in cells may induce membrane-less organelles formation involving even ordered proteins as scaffolds. Our results suggest, that both studied polyanions: prothymosin α and poly-glutamic acid, exhibit the same effect of lysozyme salting-out, to a different extent. This work was supported by the Russian Foundation of Basic Research (grant numbers 18-34-00975), and the RF President Fellowship (number SP-259.2019.4).

Physical Approaches to Cell Biology

Dynamic Crosslinking of the Actin Cytoskeleton Governs Cell Mechanics.

L. Chaubet, H. K. Heris, A. J. Ehrlicher, **A. G. Hendricks**; McGill University, Montreal, QC, CANADA.

Precise control of the cell's mechanical properties is required for cells to organize and differentiate into tissues and organs. The architecture and connectivity of cytoskeletal filaments changes in response to mechanical and biochemical cues, allowing the cell to rapidly tune its mechanics from highly-crosslinked, elastic networks to weakly-crosslinked, viscous networks. Here, we probe the frequency-dependent

viscoelastic properties of the cytoplasm in living cells using multiharmonic excitation and in *situ* optical trap calibration. At long timescales, we observe pronounced fluidization of the cytoskeleton. The mechanical response is well captured by a model where actin filaments are connected by a single dominant crosslinker. A disease-causing point mutation (K255E) of the actin crosslinker α- actinin 4 (ACTN4) renders it insensitive to tension. We show that under normal conditions, the viscoelastic properties of wild type (WT) and K255E+/- cells are similar. However, when tension is reduced through myosin-II inhibition, WT cells relax 3x faster while K255E+/- cells are not affected. Our results show that the cytoplasm behaves like a fluid at long timescales and suggest that dynamic actin crosslinking regulates relaxation.

P734/B752

Microfluidic Guillotine Reveals Multiple Mechanisms and Time Scales of Single-cell Wound Healing.

L. Blauch[1], **K. Zhang**[1], S. Cordts[1], W. Marshall[2], S. Tang[1]; [1]Department of Mechanical Engineering, Stanford University, Stanford, CA, [2]Department of Biochemistry and Biophysics, University of California, San Francisco, San Francisco, CA.

Wound healing is a key feature of living systems. At the single cell level, the ability to heal wounds underpins fundamental biological processes from cytokinesis to cancer metastasis. For some organisms, wound healing can occur in two stages: short-term sealing of the plasma membrane opening, and long-term regeneration to rebuild damaged or lost structures. While several model organisms have been developed to study single-cell wound healing, many open questions remain regarding the mechanisms and dynamics of single-cell wound healing. Here we describe a microfluidic “guillotine” as a platform to probe the mechanisms and time scales of single-cell wound healing using *Stentor coeruleus*, a giant ciliate, as our model. In this study, cells were bisected in a microfluidic guillotine, which is a knife blade fabricated inside a microfluidic channel. The cells are introduced into the guillotine at various flow rates using a syringe pump. Varying the flow rate yields two distinct wounding regimes of the guillotine (a low viscous stress Regime I and a high viscous stress Regime II). To quantify the extent of wound repair, we fixed the cells at selected time points after wounding and stained them with Sytox Green, a membrane impermeable dye. Using this assay, we found that Regime II wounds are larger, require longer repair times, and reduce survival rate compared to Regime I. Surprisingly, we observe in Regime II that after the cell is cut, the wound appears to first increase in size before closing. As an alternative wounding method, we performed laser ablation experiments on the cell membrane, and the results were consistent with both the membrane sealing time scale and the apparent increase in wound size observed using the microfluidic guillotine Sytox Green assay. Further, the survival rate derived from the Sytox Green assay agrees with the survival of observed cells over 24 hours. Finally, we highlight a few examples of using the guillotine to probe mechanisms of wound repair and regeneration. Since Ca^{2+} ion influx is a known initiator of wound repair, we confirmed that using a reduced Ca^{2+} media inhibits wound repair. Dynein inhibition by $NiCl_2$ treatment results in improper morphology at 24 hours, possibly due to the inability for the cell to reestablish polarity. Protein synthesis inhibition by cycloheximide treatment results in various defects at 24 hours, likely because regeneration requires the synthesis of new proteins to rebuild cell structures. Currently, it is unknown whether *Stentor* use the same pathways to heal wounds as classical model organisms do. We plan to test these mechanisms in *Stentor* using RNAi and drug treatments. We expect to further use the microfluidic guillotine and wound healing assay presented here to answer key questions on single-cell wound healing.

P735/B753

Nanoscale Structural Dynamics of the Cell Wall during Pole-growth in Fission Yeast.

P. D. Odermatt[1,2], K. C. Huang[2,3], F. Chang[1]; [1]UCSF, San Francisco, CA, [2]Stanford University, Stanford, CA, [3]Chan Zuckerberg Biohub, San Francisco, CA.

The rod-shaped eukaryote fission yeast is a widely used organism to study general principles governing the regulation of cell size, growth and morphogenesis. Fission yeast cells are inflated by a high turgor pressure which is counter-balanced by a rigid cell wall. Maintenance of the cell wall structural integrity while allowing remodelling of the cell wall for the cell to grow is key to survival. The cell wall is a complex structure composed of the glucose polysaccharides α-, β-glucan and glycoproteins and defines the shape of the cell. During periods of growth, new cell wall material is inserted at the cell poles, subsequently forming the cylindrical part of the cell as the pole continues to insert new wall material displacing existing material. The micron-scale cell shape and growth patterns are orchestrated by the nanoscale structural and mechanical cell wall dynamics. However, the mechanisms linking these phenomena are unknown. To study the dynamical changes of the cell wall during fission yeast growth we use time-lapse live cell atomic force microscope (AFM) imaging on poles of vertically immobilized cells. High-resolution imaging reveals the dynamic rearrangement of glucan fibers on the pole as the new pole initiates growth after new end take off (NETO) and glucan strands are being incorporated into the cell wall. The nanoscale structural rearrangement in conjunction with local mechanical properties provide unprecedented detail of the pole-growth process highlighting the contribution of the cell wall stress on incorporation and dynamical rearrangment of glucan fibers. In addition we'll characterize the role of specific steps of the cell wall biosynthetic pathway on the nanoscale cell wall structure and dynamics and establish its effects on cell shape changes. This will provide the structural and mechanical details for establishing general principles linking the cell wall rearrangement at the nanoscale to the emergence of micron-scale cell shapes.

P736/B754

Characterizing the Effect of Nick and Holiday Junction on Axial Stiffness of DNA Origami.

W. Jung[1], E. Chen[1], R. Veneziano[2], S. Gaitanaros[1], Y. Chen[1]; [1]Johns Hopkins University, Baltimore, MD, [2]George Mason University, Fairfax, VA.

The techniques of DNA origami have been applied to build nano-sized structures of a variety of geometries, ranging from rectangular boxes intended for drug delivery to robots capable of dynamic displacement. Nevertheless, the mechanical property of the DNA origami structures still remains unclear, making it difficult to predict their long-term functionality. Here, we aim to understand whether the structures of DNA origami, nick and Holliday Junction, affect its axial stiffness. Nick, the region where one staple strand ends and another begins, and Holliday Junction, the region where a staple strand extends from one double-helix bundle to another. The axial stiffness of four DNA origami structures in the shape of beams, with different number of nicks and Holliday Junctions, were examined by applying pulling forces to stretch the DNA origami using a microfluidic device. The DNA origami was immobilized on a glass surface, and stretching forces ranging from 1 pN to 30 pN were applied to the DNA origami through a micron-sized particle bound to the free end of the DNA origami. The measurement showed a 1.3-fold higher axial stiffness in the ligated DNA origami structures than the unligated ones, suggesting the presence of nick reduces the axial stiffness of DNA origami. In parallel, we also observed that reducing the number of Holiday Junctions by 50% increased the stiffness by 1.6-fold, suggesting that

Holliday Junctions weaken the structural integrity, thus decrease the stiffness of DNA origami. Our finding can provide useful rules when designing the DNA nanostructure with desirable mechanical properties.

P737/B755

Protein Condensates Are Aging Maxwell Fluids.

L. Jawerth[1], E. Fischer-Friedrich[2], A. Hyman[3], F. Julicher[1]; [1]Max Planck Institute for the Physics of Complex Systems, Dresden, GERMANY, [2]Biotechnology Center, Technische Universität Dresden, Tatzberg 47-49, 01307 Dresden, Germany, Dresden, GERMANY, [3]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, GERMANY.

Liquid-like protein condensates (LLPCs) are intracellular compartments that segregate material without the use of a membrane. The liquid-like behavior of the condensates is a defining characteristic and the viscosity, surface tension and other material properties determine how segregated species diffuse into and within condensates; they, thus, critically impact the biological function of the condensates. It has become increasingly clear that some LLPCs do not have time-independent material properties, but can, instead, transition to more solid, gel-like materials. Here, we present our efforts to quantify these new materials as they age in vitro. We measure the visco-elastic material properties of two proteins, PGL-3 and FUS, by means of a combination of active and passive microrheology. At early times, we find that the droplets behave much like simple liquids but gradually become more elastic. Surprisingly, the changing mechanical properties can all be scaled onto a single master curve using one characteristic time scale which grows as the sample ages. This and other features we observe bear a striking resemblance to the behaviors observed in materials with glass-like aging. We conclude that protein condensates are soft glassy materials with age dependent material properties that we call Maxwell glasses. We speculate on the advantages of glassy behavior for modulation of cellular biochemistry.

P738/B756

A Versatile Platform for Measuring Cellular Forces in Complex 3d Environments.

R. P. Moore[1,2], K. B. Patel[1,2], W. R. Legant[1,2]; [1]University of North Carolina, Chapel Hill, NC, [2]North Carolina State University, Raleigh, NC.

We have developed a method for measuring cellular forces within user programmable, 3D micropatterned environments. Our method uses flat or patterned polyacrylamide gels, coated in fibronectin as a substrate for cells to grow and migrate on. We control the topography of these gels by casting them on photolithographically patterned silicon wafers. With this approach, we demonstrate the ability to guide cell migration and measure cell forces within channels of various sizes that contain branches or constrictions at specified locations. We control the substrate stiffness by varying the ratio of acrylamide and bis-acrylamide as in (Tse and Engler 2010) and calculate cellular tractions by feeding the hydrogel rigidity and geometry into custom scripts in Matlab and Comsol. We are using these approaches to study the coordination between cytoskeletal dynamics and cellular tractions as human osteosarcoma cells transit through structures that mimic constrictions encountered at tissue interstices. We further demonstrate the versatility of this platform using both high-speed 3D lattice light-sheet microscopy and readily available wide field microscopes. Together, we anticipate that these methods will enable new studies of how cellular forces drive migration through a variety of complex and physiologically relevant 3D architectures.

P739/B757

Dynamically Heterogeneous Plasma Membrane Is Poised for Initiation of Receptor-mediated Mast Cell Signaling.

N. Bag, D. Holowka, **B. Baird**; Cornell University, Ithaca, NY.

Cell surface receptors distinguish specific stimuli from biological noise, and underlying mechanisms depend on the resting steady-state organization of plasma membrane components. The nanoscale distribution of signaling proteins, including kinases and phosphatases, is coordinately rearranged within the poised membrane after the receptor is stimulated by extracellular ligand, such that changes in relatively weak interactions serve to transmit the signal across the membrane. Central to membrane organization are dynamically heterogeneous features such as cortical actin meshwork and asters, ordered proteo-lipid nanodomains, and protein clusters, any or all of which may slow the diffusion of membrane components. Correspondingly, microscopic diffusion of structurally and functionally distinct components provide the means for examining nanoscale organization in resting and stimulated cells. We evaluated three key components in the early stage of mast cell signaling by measuring their diffusion in live RBL cells: FcεRI receptor for immunoglobulin E (IgE), tyrosine kinase Lyn anchored to the membrane inner leaflet, and transmembrane phosphatase PTPα. We exploited the statistical robustness of multiplexed Imaging Fluorescence Correlation Spectroscopy (ImFCS), initially to evaluate subtle diffusion differences of these proteins in resting cells. We found that interactions between its saturated lipid anchor and Lo-like lipid nanodomains govern the diffusing distribution of Lyn, which also undergoes protein-based interactions. Diffusion of transmembrane proteins, IgE-FcεRI and PTPα appears limited primarily by protein-based interactions. Antigen-crosslinking of monomeric IgE-FcεRI causes their nanoclustering and consequent stabilization of a locally ordered membrane environment. ImFCS data show that this subtly reorganized region acts as a spatial filter to facilitate co-localization of Lyn through its favorable lipid-based interactions and, simultaneously, segregation of PTPα based on unfavorable interactions of its transmembrane domain with ordered lipids and protein-based steric exclusion. Supporting this view, a Lyn chimera with unsaturated lipid anchor does not couple with antigen-crosslinked IgE-FcεRI, whereas a PTPα anchored to the membrane by saturated lipids does couple. These observations underscore the pivotal importance of organized plasma membrane heterogeneity in the poised resting state, thereby enabling orchestration of critical protein-protein interactions during stimulated transmembrane signaling. This research is supported by NIH R01GM117552.

Physical Mechanisms for Oncogene-induced Breakdown in Mammary Tissue Structure during Cancer Progression.

V. Srivastava[1], J. L. Hu[1], J. C. Garbe[2], M. R. Stampfer[2], M. A. LaBarge[3], Z. J. Gartner[1]; [1]University of California San Francisco, San Francisco, CA, [2]Lawrence Berkeley National Lanoratory, Berkeley, CA, [3]Beckman Research Institute, City of Hope, Duarte, CA.

Structural breakdown in the mammary epithelium is the hallmark of progression from ductal carcinoma in situ (DCIS) to invasive ductal carcinoma (IDC), and represents a major inflection point in the risk for patients. Normal epithelium is comprised of an inner luminal (LEP) compartment, also the site of origin for most breast cancers, that is surrounded by an outer myoepithelial (MEP) layer. Therefore, we propose that translocation of transformed LEP past the MEP layer is a key rate-limiting step preceding invasion, as most breast cancer drivers are already activated in DCIS lesions. We previously

demonstrated that reconstituted organoids containing normal human LEP and MEP (isolated from reduction mammoplasty tissue) can self-organize in vitro, and that the capacity of MEP to exclude LEP from the basal compartment is determined by hard-wired and lineage-specific interfacial tensions at each cell-cell and cell-extracellular matrix (ECM) interface. Specifically, the LEP-ECM interface is highly unfavorable compared to the MEP-ECM interface. We developed a model for self-organization driven by differences in interfacial energy, and predicted that altered interfacial tensions and dynamics (motility) promote basal LEP translocation, downstream of many cancer genes. Specifically, our model predicts that stabilization of the LEP-ECM interface and increased dynamics will increase occupancy of a high energy structural intermediate with a LEP in the basal compartment. To test this, we expressed twelve common breast cancer drivers in normal LEP, and observed that only PIK3CA-H1047R and PIK3CA-E545K expression disrupted their organization with normal MEP in 3D culture. Consistent with our predictions, PIK3CA activation increases the LEP-ECM contact angle (a measure of favorability of the LEP-ECM interface), promotes tissue dynamics and upregulates expression of several ECM molecules. Further, we used chemical inhibitors to show Akt activation downstream of PIK3CA is necessary for tissue disorganization. Collectively, these results show that signaling downstream of PIK3CA, a pathway dysregulated in >70% of breast cancers, drives the physical changes necessary for the structural transition that is a prerequisite for invasion. A more mechanistic understanding of the physical and molecular changes driving this transition will benefit the patients currently being overtreated due to lack of good markers for IDC progression.

Deciphering Mechanisms of Lipid Droplet Biogenesis.

A. Santinho, A. Thiam; Ecole Normale Superieure, Paris, FRANCE.

Lipid droplets (LDs) play a central role in cellular energy balance and are implicated in several biological processes. They are unique organelles as they are made by a neutral lipid core covered by a phospholipid monolayer, while other cellular organelles have a bilayer. LD biogenesis occurs at the endoplasmic reticulum (ER) phospholipid bilayer. During lipid storage conditions, neutral lipid oil molecules synthesized in the ER are encapsulated in between the monolayers composing the ER bilayer. At a critical concentration, the free neutral molecules demix and phase separate from the bilayer to nucleate a droplet. This nucleation step requires to cross an energy barrier which likely depends on membrane biophysical parameters such as tension, curvature or physicochemistry. However, it is unclear how these parameters impact LD nucleation from a bilayer. We opted for an in vitro reconstitution approach to study processes of LD nucleation. We incorporated neutral lipids into giant unilamellar vesicles to reconstitute situations prior LD nucleation. This system enabled to modulate membrane physicochemical and biophysical properties so as to depict parameters critical for phase separation of the neutral lipids and nucleation of a droplet. We found that membrane topology and tension control neutral lipid distribution in a bilayer. Indeed, we observed differential enrichment of neutral lipids between planar and tubular membrane regions. This led us to identify that membrane curvature modulates the energy barrier for nucleation and plays a key role in LD formation in a bilayer. In cells, several proteins have been reported to play key roles in LD nucleation. Our in vitro approach reveals that proteins are rapidly recruited to nucleated droplet and stabilize them by preventing their disappearance. Our approach for studying these early steps of LD biogenesis facilitated the identification of key parameters acting during this process. Clearly, its incrementation by the incorporation of more relevant membrane proteins will enable to address and better understand key questions of LD biology.

Nuclear Bodies Undergo Heterogeneous Nucleation Near the Binodal Line in Mitosis.

S. F. Shimobayshi[1,2], M. Haataja[1], C. P. Brangwynne[1,3]; [1]Princeton University, Princeton, NJ, [2]Japan Agency for Marine-Earth Science and Technology (JAMSTEC), Yokohama, JAPAN, [3]Howard Hughes Medial Institute, Princeton, NJ.

Living cells utilize compartmentalization to concentrate certain biological molecules (protein, RNA, and lipids). The compartmentalization is carried out not only through membranes, which are composed of lipids bilayers and proteins, but also by liquid-liquid phase separation, which leads to membrane-less organelles or condensates. The membrane-less organelles or condensates disassemble and reassemble in mitosis during cell cycle; however, the biophysics of the process is poorly understood. Taking advantage the optoDroplet system we recently developed, we demonstrate that membrane-less organelles or condensates in nucleus (nuclear bodies)undergo heterogeneous nucleation near the binodal line in mitosis. Our findings give energetic understanding on how the cells spatio-temporally control the nucleation during cell cycle.

Mechanotransduction and Migration of *Dictyostelium on* Substrates of Different Stiffnesses.

Y. Wu[1], T. Osterday[2], **K. Cooper**[2]; [1]University of Wisconsin - Platteville, Platteville, WI, [2]Loras College, Dubuque, IA.

The stiffness of adherent mammalian cells is regulated by the elasticity of substrates due to mechanotransduction via integrin-based focal adhesions. *Dictyostelium discoideum* is an ameboid protozoan organism that does not carry genes for classical integrin and can adhere to substrates without forming focal adhesions. It also has a life cycle that naturally includes both single-cellular and multicellular life forms. We report the measurements of the elastic modulus of single cells on varied substrate stiffnesses and the elastic modulus of the multicellular “slug” using atomic force microscopy (AFM) as a microindenter/force transducer. The results show that the elastic modulus of the *Dictyostelium* cell is regulated by the stiffness of the substrate and its surrounding cells (Wu, Y and Cooper, KM, 2019). We also investigate the migration of the cells on substrates of different stiffnesses.

Extracellular Potential Measurement of Heart Tissue Pieces for Cardiotoxicity Testing Technology.

K. Emura, 1840002, T. Kaneko; Hosei University, koganei, JAPAN.

Arrhythmia in the heart is one of the fatal diseases for the living body. Development of drugs in which arrhythmia may appear as a side effect may be stopped, and safety assessment is required at an early stage of development. As a means for solving this problem, Multi-Electrode Array (MEA) system is attracting attention. The MEA system is a device that measures the extracellular potential of cells and tissues present on MEA electrodes. The extracellular potential waveform of cardiomyocytes consists of peaks due to the inflow and outflow of three types of ions, Na^+, Ca^{2+}, and K^+. The potential from the Na^+ peak to the K^+ peak is the Field Potential Duration (FPD). It is used as an index corresponding to the QT interval. In addition, Short Term Variability (STV), which is a fluctuation including temporal factors, was calculated for FPD. In this study, a heart tissue piece derived from a chick embryo is placed on electrode,

its extracellular potential is measured. The cardiotoxicity of the drug is evaluated using E-4031, which is known to cause QT prolongation. We verified whether this is possible. The cardiotoxicity of 0.1 nM-1 μM E-4031 was verified in a 37°C incubation box and a CO_2 incubator. As a result, similar to the results with the previous human ES cell-derived cardiomyocyte mass, the addition of 1 μM E-4031 prolongs the FPD. E-4031 has the effect of specifically suppressing the K^+ channel, and it was confirmed that the K^+ peak of the waveform gradually decreased at 1 μM E-4031. In the CO_2 incubator, the STV of FPD was about 6 times that before the addition of E-4031 at 100 nM although FPD did not change. Previous results from human ES cell-derived cardiomyocyte clusters suggest that there is a possibility of cardiotoxicity when the STV value exceeds 1.9 times that before E-4031 addition. In this study, extracellular potential measurement using chick-embryo-derived heart tissue pieces detected cardiotoxicity at 100 nM, which has been reported to inhibit K^+ channels in existing in vitro cardiotoxicity tests. Therefore, it was suggested that CO_2 incubator experiments using chick-embryo-derived heart tissue pieces are useful.

Rigidity Dependent Spontaneous Epithelial Tissue Rupture.

S. Sonam[1], **L. Balasubramaniam**[1], J. Rupprecht[2], Y. Ivan[3], C. Jebane[1], M. Fardin[1], Y. Toyama[3], P. Marcq[4], J. Prost[5], R. Mège[1], B. Ladoux[1]; [1]Institut Jacques Monod, Paris, FRANCE, [2]CENTURI institute, Centre de Physique Théorique in Aix-Marseille University, on Luminy campus, Marseille, FRANCE, [3]Mechanobiology Institute, Singapore, SINGAPORE, [4]Laboratoire Physique et Mécanique des Milieux Hétérogènes (UMR 7636), ESPCI - SU - UPD, Paris, FRANCE, [5]Institut Curie, Paris, FRANCE.

.

Epithelial integrity is a primary tissue function which protects the organs from abrasion and environmental exposure. Instability or gaps in this protective epithelial layer is a rare event. Studies in intestinal epithelium have shown gaps in the tissue after an apoptotic event[1]. Remarkably gaps in the epithelial have been observed upon mechanical load in lung epithelium[2] or in drosophila wings upon the loss of cell-cell adhesion[3]. However, the mechanism of this gap formation is still unclear. In our 2D in-vitro epithelial culture system (MDCK) we observe spontaneous gap formation in a substrate rigidity dependent manner. The size of these gaps can vary from 1-10 cell size. These gaps are able to seal themselves below a maximal gap size of about 4000μm^2. We observed two sources of gap formation: 1) from an edge of a stretching cell causing it to detach from its neighboring cell and 2) After cytokinesis and failure of complete sealing between the two daughter cells. We also observe that these gaps are formed in regions of high isotropic tensile stress characterized by -1/2 nematic defects. In the first case when cells get stretched prior to gap formation, we notice a peak in Von-Mises stress 30-60 minutes prior to gap formation. Von-Mises stress a term borrowed from material science determines the ductile to brittle yielding of a material. This has also been shown to be a leading cause of tissue rupture in *Trichoplax adherens*[4]. References 1. Watson, A. J., Duckworth, C. A., Guan, Y. An d Montrose, M. H. Towards Structural an alysis of the Intracellular Pathogen Response Pathway in *Caenorhabditis Elegans*.

Y. Chang[1], P. Jaroenlak[1], S. Gang[2], G. Bhabha[1], E. Troemel[2], D. C. Ekiert[1,3]; [1]Skirball Institute, Department of Cell Biology, NYU School of Medicine, New York, NY, [2]Division of Biological Sciences, University of California, San Diego, La Jolla, CA, [3]Skirball Institute, Departments of Cell Biology and Microbiology, NYU School of Medicine, New York, NY.

Pathogen infection can perturb protein homeostasis (proteostasis) of the host. Therefore, organisms have evolved defensive mechanisms to sense pathogens and mount a protective response. For infections caused by microsporidia and viruses in *C. elegans*, the intracellular pathogen response (IPR) pathway is important for maintaining proteostasis. In the IPR pathway, PALS-25 and PALS-22 act as positive and negative regulators of genes induced by microsporidia and virus infection, including cullin-RING ubiquitin ligase components CUL-6, SKR-3, 4, 5 and RCS-1. PALS-22 and PALS-25 are two members of the broadly expanded family of 39 PALS proteins encoded in the *C. elegans* genome, but share no detectable sequence similarity with other proteins of known structure or function. Preliminary research shows that PALS-22 and PALS-25 interact to form a complex, suggesting that PALS-22/PALS-25 physical association may balance these opposing regulators of the IPR and serve as an ON/OFF switch to regulate expression. Moreover, mutations in the cullin ligase complex components-CUL-6 and SKR3, 4, 5-are required for protection from proteasomal stress, indicating that CUL-6-SKR is potentially part of an effector complex of PALS-22/25. However, the structures of PALS-22/PALS-25 and how the switch pair regulates the cullin ligase complex are unknown. We aim to express PALS-22, PALS-25 and the CUL-6-SKR-3 ligase complex, and investigate the molecular mechanism of IPR pathway by solving the structure of these proteins using X-ray crystallography. Bioinformatics analysis of the PALS-22 and PALS-25 protein sequences suggest that both proteins may contain helical bundles such as coiled-coils. Recently, we have successfully purified PALS-22 and are working to express soluble PALS-25, possibly by co-expressing PALS-25 with its binding partner PALS-22. In parallel, we are working to co-express the components of the cullin ligase complex-SKR-3 and CUL-6. Our biochemical and structural studies of the interactions of PALS-22/PALS-25 and the cullin-RING ubiquitin ligase complex will give the insight into how these key factors contribute to the IPR pathway in *C. elegans*.

Single-molecule an alysis of the Role of Fad in the Conformational Landscape Od Drosophila Cryptochrome.

S. Foroutannejad, 20057[1], R. Maillard[1], C. Lin[2], B. Crane[2]; [1]Georgetown University, Washington, DC, [2]Cornell University, Itacha, NY.

The circadian clock regulates biological and behavioral adaptations in response to day-night cycles. Cryptochromes (CRYs) are members of a family of photolyases involved in DNA repair that are responsible for the oscillation of the circadian clock. CRYs harbor a conserved flavin adenine dinulcleotide (FAD), which is reduced by light and induces conformational changes to activate the

protein. The underlying mechanisms of the light-induced conformational changes of CRYs coupled to FAD reduction, however, are still not well understood. In this study, we use optical tweezers to study the conformational landscape of the *Drosophila* CRY (dCRY) in the presence and absence of FAD, and in light and dark conditions. In the presence of FAD, dCRY unfolds in several steps whose total extension correspondS to the fully folded protein. In contrast, in the absence of FAD the protein fails to fold into its native tertiary structure. By titrating FAD and monitoring the fraction of folded protein, we constructed a single-molecule binding curve and determine a Kd for FAD of 2 nM. Interestingly, the flavin mononucleotide (FMN) moiety binds with a Kd similar to that of FAD and promotes complete folding, whereas the dinucleotide moiety (adenine and phosphate groups) contribute very little to the binding interactions of FAD and has no effect on the fold of the protein. These results indicate that FMN is the dominant moiety responsible for the binding energy of FAD, and that FAD is strictly required for the global structural integrity and stability of the protein. Lastly, the individual unfolding steps in the dark and light conditions indicate slightly higher unfolding forces in the dark state. This result may explain the kinetics of proteasome degradation of dCRY: the light-activated dCRY is less stable which is favored for the cell energetically to remove the protein at the end of each day cycle in response to the environmental lights.

P748/B766

Molecular Mechanism Underlying Protein and Ribonucleic Acid Aggregation.

J. KANG, 23516, S. Lee; Pusan National University, Busan, KOREA, REPUBLIC OF.

For a decade, protein aggregation has been considered to be a main cause of several diseases including Alzheimer's disease (AD) and Parkinson's disease (PD). Many researchers have been struggling to understand the molecular mechanism underlying protein aggregation. Up to now, one of the leading theories is that Mg^{2+} and Ca^{2+} are the two main metal ions that function to create protein aggregates in cells. That being said, there is a very low concentration of metal ions in cells, present only on a micromolar scale. In fact, many millimolar of metal ions are required to induce such protein aggregation. Here, we are interested in finding very small molecules on a millimolar scale that are multivalent, since aggregated proteins are hyper-phosphorylated. Among small molecules in cells, we were interested in the two polyamines spermine and spermidine since they are highly positively charged and exist in high concentration in human cells. Nucleoside triphosphates (NTPs) has three phosphorylated groups that interact electrostatically with polyamines, making them a good model to explain the creation of RNA granules as well as the aggregation of phosphorylated proteins. In this study, we investigated spectral changes of NTPs as a function of polyamine concentration. We found that the absorption band of ATP red-shifted and that of GTP showed a different spectral feature: π-π^* transition red-shifted and *n*-π^* transition blue-shifted with increasing concentration of polyamines. In addition, we found that a new absorption band of ATP and GTP appeared and evolved over time. This indicates that the aggregates of ATP and GTP grow over time. Thus, we conclude that polyamines are very critical in creating biomolecular aggregates.

P749/B767

Studying Habituation in Single-cell Ciliate *Stentor Coeruleus.*

T. Makushok, W. F. Marshall; University of California, San Francisco, San Francisco, CA.

Habituation, the decrease in an organism's reaction to repetitive stimulations, is studied extensively in metazoans. Intriguingly, a number of single-cell organisms have been shown to exhibit habituation as well. *Stentor coeruleus* is a particularly good model system to study habituation in single cells. *S. coeruleus* response to mechanical stimulations is very clear-cut (the cell contracts from a trumpet-like shape to a sphere), which simplifies the interpretation of the results, and the time scale of the experiment is rapid. Its large size (about 1 mm long) and vibrant color simplify the imaging and image analysis. We developed Arduino-based setup that allows to mechanically stimulate the cells (by shaking their container) in a fully automated fashion. The reaction of the cells to a series of stimulations was imaged with a microscope, and the images processed to extract the dynamics of *Stentor* habituation. The advantages of this method include its fully automated nature and the ability to control the timing of the stimulations via the Arduino, which gives a lot of flexibility in experimental design, as well as allows to track the response of individual cells throughout the habituation experiment. We have shown that *Stentor* habituation can be modeled using a two-state model. Using this model, we have explored a range of habituation parameters both experimentally and computationally.

P750/B768

Utilizing Scanning Probe Microscopy for Biophysical Characterization of Fission Yeast.

E. Gibbs, J. Hsu, J. Goss; Wellesley College, Wellesley, MA.

Cells continuously contribute to and remodel their extracellular environment, which in turn helps them to maintain their structure and interact with their surroundings. The fission yeast, *Schizosaccharomyces pombe*, generates a proteoglycan cell wall that serves as a protective barrier, structural support, and resistive force to cellular turgor pressure. Despite having a detailed understanding of its composition, only a limited number of studies have explored biophysical properties of the *S. pombe* cell wall. Atomic Force Microscopy (AFM) is a form of scanning probe nano-microscopy that uses a cantilever to trace a biosurface, obtaining a topographical scan and/or applying force to measure biophysical properties such as surface stiffness, adhesion, and roughness. In this study, we utilized AFM for the first time in quantification of fission yeast cell wall elasticity to better understand how it contributes to overall cellular structure and function. We also evaluated cell wall stiffness in response to osmotic stress and observed increased elasticity. These initial measurements provide a baseline for investigating how fission yeast cell wall stiffness varies under different environmental pressures and how individual cell wall components contribute to the overall strength and stability.

Measuring Protein Concentrations in Biomolecular Condensates Via Quantitative Phase Microscopy.

P. M. McCall[1,2,3], K. Kim[4,5], J. Wang[1], A. W. Fritsch[1,2,3], A. Poznyakovskiy[1], B. Diederich[6], M. Kreysing[1,3], R. Heintzmann[6,7], J. Guck[4,5], S. Alberti[4], J. Brugués[1,2,3], A. A. Hyman[1]; [1]Max Planck Institute for Molecular Cell Biology and Genetics, Dresden, GERMANY, [2]Max Planck Institute for the Physics of Complex Systems, Dresden, GERMANY, [3]Center for Systems Biology Dresden, Dresden, GERMANY, [4]Biotechnology Center, Technische Universität Dresden, Dresden, GERMANY, [5]Max Planck Institute for the Science of Light,

Erlangen, GERMANY, [6]Leibniz Institute of Photonic Technology, Jena, GERMANY, [7]Institute of Physical Chemistry and Abbe Center of Photonics, Friedrich-Schiller-University, Jena, GERMANY.

Many membrane-less compartments in eukaryotic cells are protein-rich biomolecular condensates formed via macromolecular phase separation from the cyto- or nucleoplasm. The resultant coexisting phases are characterized by differences in composition. Condensates are typically highly enriched in a relatively small number of distinct “scaffold” protein and RNA species relative to the coexisting dilute phase, with additional modest enrichment in a much larger set of “client” molecules. Although it is clear that knowledge of condensate composition is essential for a full biophysical description of the physicochemical properties and associated functions of biomolecular condensates, measurements of composition provide a number of technical challenges, even in minimal model systems of a few purified components. To address this, we use quantitative phase microscopy and optical diffraction tomography to measure the 3D refractive index distribution of model condensates formed in vitro. Here, model condensates are formed by phase separation of purified protein constructs derived from the primarily disordered RNA-binding domain (RBD) of TAF15, a member of the well-studied FUS/EWSR1/TAF15 protein family. From the measured refractive index, we calculate the protein concentration of the condensed branch of the two-phase coexistence curve. Surprisingly, we find that phase separation of TAF15(RBD) is only weakly attenuated by salt, with robust phase separation observed at KCl concentrations ranging from 50 mM to more than 3 M. This suggests that, despite the large number of charged residues in the RBD, coulomb interactions play only a minor role in the protein-protein interaction potential. We find that the protein concentration in TAF15(RBD) condensates is a decreasing function of temperature, indicative of the existence of an upper critical solution temperature beyond 50 C. Interestingly, we also find that partition coefficients determined by confocal fluorescence microscopy dramatically underestimate the concentrations of scaffold proteins in condensates. A simple mathematical model incorporating inner filter and ground-state depletion effects suggests that the discrepancy stems primarily from differences in the fluorescence quantum yield between the dilute and condensed phases.

P752/B770

Impact of the Ecm Stiffness and Geometry in the Collective Dynamics of Epithelial and Mesenchymal Lung Cells.

D. Pérez-Calixto[1,2,3], F. Toscano-Márquez[4,5], J. Cisneros[5], G. Vázquez-Victorio[1,2], M. Hautefeuille[1,2]; [1]UNAM Universidad Nacional Autonoma De Mexico, Ciudad de México, MEXICO, [2]LaNSBioDyT-Facultad de Ciencias, UNAM., Ciudad de México, MEXICO, [3]Posgrado en Ciencia e Ingeniería de Materiales, Ciudad de México, MEXICO, [4]Posgrado en Ciencias Biologicas, UNAM, Ciudad de México, MEXICO, [5]Instituto Nacional de Enfermedades Respiratorias, “Ismael Cosío Villegas”, Ciudad de México, MEXICO.

The cell microenvironment is composed of a wide range of mechanical stimuli that influence the behavior, fate and function of cells. Some originate from the local intrinsic properties of the materials that constitute the extracellular matrix, such as: stiffness, geometry and chemical composition. In addition, cell microenvironment is in constant dynamic activity since it can be modified by the cells. These stimuli in the right values maintain the cell homeostasis and any disturbance of these parameters may induce a response of cells. Due to alterations in collective behavior are associated with pathological processes such as cancer metastasis and fibrosis, it is necessary to study and characterization topological and mechanical intrinsic properties of cell microenvironment, as well as how those properties influence

the collective dynamics (long range directional order, self-organization) of cells that form organs and tissues. In order to elucidate the impact of the stiffness and geometry of the extracellular matrix on cells collective dynamics first, we seeded alveolar epithelial cells (A549) on polyacrylamide hydrogel substrates with different stiffnesses. Besides, the system was disturbed by adding the transforming growth factor beta (TGFβ) to the A549 cell culture, since TGFβ is related to the mesenchymal epithelial transition and generally modifies the cell morphology. Therefore, the morphological and phenotype of the cells were analyzed by immunofluorescence and western blot assays, which were compared with normal human lung fibroblast (NHLF). Then, we approached the problem of collective dynamics by modelling the epithelium and fibroblasts as an active nematic liquid crystal that presents a long range directional order. We observed a decrease of the activity in the cells seeded on stiffer hydrogels together with the emergence of topological defects, whereas in soft gels the activity increased, interfering with the collective nematic order. Finally, cells were seeded on alveoli-shaped structures of polyacrylamide hydrogels in order to study the influence of geometric constraints on the collective dynamics and cells phenotype. Furthermore, we also observed an heterogeneous mechanical response of the cell layer associated to the stiffness and geometric constraints of the substrates. These results provide a deeper insight towards the understanding of the cellular response to the combined influence of several external stimuli in different pulmonary pathologies associated with an increase in lung tissue stiffness and overexpression of TGFβ.

P753/B772

Pou3f4 in the Otic Mesenchyme Is Essential for Development of Normal Spiral Ganglion Neuron Innervation Patterns in the Mammalian Cochlea.

M. Gurjar, J. Jung, V. Balendran, E. Staab, T. M. Coate; Georgetown University, Washington, DC.

Mutations in the Pitt-Oct-Unc (POU)-domain transcription factor *Pou3f4*, located on the X-chromosome are associated with X-linked nonsyndromic hearing loss in the DFNX2 locus. Pou3f4, which is specifically expressed by otic mesenchyme cells, regulates the expression of various Ephs and Ephrin proteins that act as axon guidance cues for spiral ganglion neurons (SGNs). During development, SGNs interact with otic mesenchyme cells prior to forming synapses with hair cells. I will discuss our preliminary findings on how Pou3f4 normally inhibits *Efna1* (Ephrin-A1) and *Efna2* (Ephrin-A2) ligand expression. RNAScope assays show *Efna1* and *Efna2* mRNAs are normally expressed at low levels by otic mesenchyme cells, and that their expression increases about two-fold in *Pou3f4* knockout cochleae. These studies were carried out using mice at E15, which is the time when SGNs begin to fasciculate as they innervate hair cells. Preliminary chromatin immunoprecipitation assays have identified binding sites for Pou3f4 in Efna1 and Efna2 genes. Initial analyses of Efna1 and Efna2 double knockout cochleae show subtle differences in SGN innervation patterns compared to WT littermate controls. Both Ephrin-A1 and Ephrin-A2 attract growing SGN processes in in vitro assays. Hence, we hypothesize that Ephrin-A1 and Ephrin-A2 proteins on otic mesenchyme cells serve as attractive cues for SGN axons and are normally repressed by Pou3f4 to promote axon fasciculation. Additionally, I will discuss our ideas for future work to determine the Eph receptor binding partners for Ephrins-A1 and -A2 on SGNs and genetic experiments to determine whether *Efna1* and *Efna2* knockout alleles can rescue the SGN fasciculation defects observed in *Pou3f4* knockout cochlea. Determining the molecular basis for proper cochlear innervation

patterns through these studies and others will help in developing therapeutics for people with sensorineural hearing loss.

P754/B773

Development of Ependymal and Postnatal Neural Stem Cells and Their Origin from a Common Embryonic Progenitor.

S. A. Redmond[1], M. Figueres-Onate[2], K. Obernier[1], M. Assis Nascimento[1], J. I. Parraguez[1], L. Lopez-Mascaraque[2], L. C. Fuentealba[1], A. Alvarez-Buylla[1]; [1]UCSF, San Francisco, CA, [2]Instituto Cajal-CSIC, Madrid, SPAIN.

The adult mouse brain contains an extensive neurogenic niche in the lateral walls of the lateral ventricles. This epithelium, which has a unique pinwheel organization, contains multiciliated ependymal (E1) cells and neural stem cells (B1). This postnatal germinal epithelium develops from the embryonic ventricular zone, but the lineage relationship between E1 and B1 cells remains unknown. Distinct subpopulations of radial glia (RG) cells in late embryonic and early postnatal development either expand their apical domain >11-fold to form E1 cells or retain small apical domains that coalesce into the centers of pinwheels to form B1 cells. Using independent methods of lineage tracing, we show that individual RG cells can give rise to clones containing E1 and B1 cells. This study reveals key developmental steps in the formation of the postnatal germinal niche and the shared cellular origin of E1 and B1 cells.

P755/B774

Scribble and Vangl2 Interact to Influence Neural Tube Morphogenesis.

A. C. Lesko, A. E. Sutherland; University of Virginia School of Medicine, Charlottesville, VA.

Neural tube defects (NTD) occur in 1:500 pregnancies resulting in significant health effects or even death for affected infants. Neural tube closure in vertebrates relies on convergent extension, driven by polarized cell intercalation, and bending of the epithelium through apical constriction. These processes are regulated by the Planar Cell Polarity (PCP) pathway and mutations of PCP proteins such as Vangl2 result in NTD. In addition, mutation of the gene encoding Scribble (Scrib) which is best known for its role in regulating apical-basal polarity and junctional organization, also causes NTD. *Line90 Scrib mutants* (*Scrib^{L90}*), containing a point mutation in the N-terminal LRR domain, display open neural tube (ONT). Interestingly, *Scrib^{L90} mutants* genetically interact with *Vangl2 Loop-tail mutants (Vangl2^{Lp})* to cause NTD. However the molecular mechanisms by which Scrib and Vangl2 interact, and the cellular and biochemical effects of *Scrib* mutations on neural tube development remain unknown. **We hypothesize that Scrib and Vangl2 cooperatively interact to promote polarized cell intercalation and apical constriction during neural tube morphogenesis. To** assess interactions between Scrib and Vangl2 we compared the neural phenotypes of double heterozygotes resulting from *Scrib^{L90} mutants* crossed to either *Vangl2^{Lp} mutants* or mutants with knockout of *Vangl2* (*Vangl2^{KO}*). While 80% of *Scrib$^{L90-/-}$* exhibit ONT only 16% of *Scrib$^{L90+/-}$ Vangl2$^{Lp+/-}$ and* 14% of *Scrib$^{L90+/-}$ Vangl2$^{KO+/-}$* do so. Additionally, our preliminary data show that *Scrib$^{L90-/-}$ Vangl2$^{KO-/-}$* do not exhibit more severe phenotypes than either *Scrib$^{L90-/-}$* or *Vangl2$^{KO-/-}$ mutants* alone suggesting Scrib and Vangl2 act within the same pathway to influence neural morphology. Interestingly mature *Scrib$^{L90+/-}$ Vangl2$^{Lp+/-}$* females all present with imperforate vagina, suggesting the interaction between Scrib and Vangl2 also influences the development of the female reproductive tract. This result along with the observation that *Scrib$^{L90+/-}$ Vangl2$^{KO+/-}$* phenotypes are less

severe than *Scrib*$^{L90+/-}$ *Vangl2*$^{Lp+/-}$ suggest that the *Vangl2*$^{Lp+/-}$ mutation acts in a dominant negative manner to affect Scrib function. Though it is clear that the interaction between Scrib and Vangl2 disrupts neural tube formation, how the loss of these proteins affects neural cell behavior remains unknown. Our preliminary live imaging data show that *Scrib*$^{L90-/-}$ *mutants* do not undergo proper convergent extension. Future studies will detail the effects of loss of Scrib on polarized cell intercalation and apical constriction through live imaging analysis of neural cell behavior. These studies will determine the cellular and molecular mechanisms by which Scrib regulates tissue structure and organization during mouse neural tube development.

The Chemokine-like Protein Fam19a3 Is Expressed by Cone Photoreceptors and OFF Cone Bipolar Cells in Mouse Retina.

S. PAPAL, L. Dong, A. Swaroop; NIH/NEI, Bethesda, MD.

Chemokine signaling has been implicated in retinal development, homeostasis and diseases. Secretion of chemokines by retinal pigment epithelium, Muller cells, astrocytes and microglia has been extensively studied in pathologies. However, little is known about the constitutive expression of chemokines by healthy retinal neurons and their function in retinal development and function. Transcriptome profiling of flow-sorted GFP+ cells in *Nrl*-GFP:*Nrl*$^{-/-}$ (S-cone-like cells) and *Nrl*-GFP:*Nrl*$^{+/+}$ (rod photoreceptors) at postnatal day (P)2, P4, P6, P10, P14 and P28 demonstrated that Fam19a3, a brain-specific chemokine-like protein is highly expressed in S-cone-like cells suggesting a specific role of this gene in cone function. We further analyzed the expression of Fam19a genes (*Fam19a1-5*) in our transcriptome data and found that *Fam19a3* was the only member of the family enriched in S-cone-like photoreceptors. Using in *situ* hybridization, we explored the expression of Fam19a3 during normal retina development and found that *Fam19a3* was specifically expressed by cones and bipolar cells. Fam19a3 protein expression was analyzed using a *Fam19a3-FLAG-T2A-Cherry* reporter mouse model and the protein was detected in cone photoreceptor inner segment and cell body as well as in type 3b OFF cone bipolar cells. Moreover, we observed a gradient in Fam19a3 expression during development that recapitulates bipolar cells maturation. Our studies demonstrated that *Fam19a3* is specifically expressed in cone photoreceptors and OFF cone bipolar cells in retina. The specific expression pattern of Fam19a3 suggests a role of this protein in the development, function and/or maturation of these cell types.

P757/B776

An Adhesion Code Enables Robust Pattern Formation in the Zebrafish Spinal Cord.

T. Tsai[1], M. Sikora[2], C. Heisenberg[2], S. Megason[1]; [1]Harvard Medical School, Boston, MA, [2]Institute of Science and Technology, Klosterneuberg, AUSTRIA.

An outstanding question in embryonic development is how different cell types reach their final positions correctly, despite large scale cellular re-arrangement during tissue morphogenesis. To achieve this, cell fate specification needs to be coordinated with regulated cell migration and adhesion, yet the mechanisms are not well-understood. In the zebrafish spinal cord, thirteen neural progenitor domains, each consisting of distinct cell type, are specified along the ventral-to-dorsal axis by opposing gradients of Shh and BMP/Wnt. The Shh signal is noisy, resulting in cells specified in a mixed pattern, requiring that individual cells be sorted to resolve this mixed pattern into well-separated domains. Here we set out to test if differential adhesion plays a role in assisting pattern formation during zebrafish spinal cord

development. We developed two cell-based mechanical assays based on micropipette aspiration to measure adhesion forces and adhesion preferences among three types of neural progenitors (p3, pMN, and p0 cells). Interestingly, each cell type exhibited preference to selectively stabilize homotypic contact and adhered more strongly to cells of the same type. A subsequent transcriptomic and genetic analysis revealed three adhesion molecules (N-cadherin, Cadherin 11, and Protocadherin 19) that are differentially expressed among the three cell types, forming a three-molecule adhesion code. When the expression levels of these adhesion molecules are perturbed, the adhesion preference to cells of the same type is lost, and the neural progenitor pattern in the spinal cord is disrupted in *vivo*. These findings allow us to propose an "adhesion code" mechanism that promotes cell sorting during tissue scale patterning. While the conventional view of spinal cord patterning is heavily focusing on interpretation of biochemical signals and transcriptional regulation, our findings suggest cell adhesion is a critical contributor to enable precise patterning in a tissue that is undergoing dramatic morphogenetic movement.

Signaling and Mechanics-based Models of Posterior Lateral Line Self-organization.

D. Dalle Nogare, **A. Chitnis, 20892**; NICHD, Bethesda, MD.

The posterior Lateral Line primordium is a group of about a hundred cells that migrates under the skin from near the ear to the tip of the tail periodically forming and depositing neuromasts to pioneer formation of the zebrafish Lateral Line sensory system. We describe how local activation coupled with long-range inhibition, operating via both signaling and mechanical interactions, potentially contribute to periodic formation and deposition of neuromasts by the migrating primordium. Wnt and Fgf signaling locally inhibit each other in leading and trailing zones of the migrating primordium, respectively, while Fgfs secreted by leading cells activate their receptors at a distance to promote Fgf signaling in a trailing zone. We use agent-based modelling to show how these interactions can determine periodic formation of Fgf signaling centers in the wake of a progressively shrinking, initially broad, Wnt domain. Center-biased Fgf signaling centers generated by these interactions provide the context for specification of central cells as sensory hair cell progenitors via Notch mediated lateral inhibition and the periodic reorganization of cells to form epithelial rosettes in the developing neuromasts. Independent observations suggest that primordium cells form adhesive links with cells within a defined neighborhood and pull them closer. As cells get closer, more cells can be pulled in. This local aggregation is inhibited by traction forces associated with collective migration, and the balance influences the emergent number and size of self-organized epithelial rosettes. We show how agent-based models based on such mechanical interactions can also make effective predictions about the pattern of neuromast formation and deposition by the migrating primordium under a variety of experimental conditions.

Defective Axonal Transport of Presynaptic Cargoes Associates with Autism-like Synaptic Dysfunction and Social Behavioral Traits.

G. Xiong, 20892-3706, X. Cheng, T. Sun, Y. Xie, N. Huang, M. Lin, S. Li, Z. Sheng; National Institutes of Health, BETHESDA, MD.

The formation of new synapses and maintenance and remodeling of mature synapses require effective axonal delivery of newly synthesized presynaptic cargoes from the soma to distal synapses, raising the

fundamental question of whether impaired axonal transport is associated with neurodevelopmental disorders such as autism spectrum disorders (ASDs). ASDs are characterized by impaired social interactions and communication along with restricted interests and stereotyped repetitive behaviors. While postsynaptic mechanisms play an important role in susceptibility to ASD, a direct link between altered axonal transport and autism etiology has not been established. Specifically, it remains unknown whether altered axonal transport of presynaptic cargos and thus reduced formation, maturation, or maintenance of presynapses contribute to ASD-like synaptic dysfunction and behavioral abnormalities. Investigations into axonal transport mechanisms in an in *vivo* model system will provide the essential information necessary to identify core presynaptic defects of ASDs. Here, we report that altered axonal transport of presynaptic cargos and thus reduced formation and maturation of synapses are one of core presynaptic mechanisms underlying synaptic dysfunction and social behavioral abnormalities. Syntabulin acting as a development-regulated motor adaptor linking kinesin-1 and presynaptic transport cargos. Syntabulin expression in mouse brain peaks during the first two weeks of postnatal development and progressively declines during brain maturation. Conditional *syntabulin*$^{-/-}$ mice (*stb* cKO) display impaired axonal transport of presynaptic cargos, reduced synapse density and active zones, and altered synaptic transmission and long-term plasticity. Intriguingly, *stb* cKO mice exhibit core autism-like traits, including defective social recognition and communication, increased stereotypic behavior, and impaired spatial learning and memory. Our study is further confirmed by an autism-associated missense STB variant that loses its motor adaptor capacity and fails to rescue *stb* cKO phenotypes. These disrupted synaptic plasticity and abnormal behaviors establish the *stb* mutant mouse as a promising autism model for investigations into the core presynaptic defects at the onset of ASDs. Thus, our study elucidates a new axonal transport mechanism underlying synaptic and behavioral abnormalities that bear similarities to human autism (Supported by the Intramural Program of NINDS, NIH).

Identifying New Developmental Functions for Genes Associated with Intellectual Disabilities.

M. Lasser[1], L. Pizzo[2], C. Monahan[1], J. Buldoc[1], S. Kim[1], L. Murphy[1], A. Oh[1], C. O'Brien[1], S. Lee[1], S. Girirajan[2], L. Lowery[1]; [1]Boston College, Chestnut Hill, MA, [2]Pennsylvania State University, State College, PA.

Intellectual disabilities (ID) are complex neurodevelopmental disorders that affect a significant portion of the general population and can be an immense health issue. Genetic mutations caused by rare copy number variants (CNVs) have been shown to play a role in ID and severe developmental delays. In particular, one CNV was identified in a subset of children diagnosed with ID that results in a heterozygous deletion of six genes at chromosome 16p12.1. Individuals with this deletion can display a variety of additional symptoms including craniofacial abnormalities, microcephaly, cardiac defects, seizures, and growth retardation. Some patients also have a second CNV mutation, or 'second-hit', elsewhere in the genome, which increases the severity of their symptoms. While some information is known regarding the function of the genes associated with this deletion, it is still unclear what their roles are in the context of vertebrate embryonic development. Thus, we sought to elucidate the function of these genes during development using genetic manipulation strategies to reduce gene dosage and observe phenotypic differences in *Xenopus laevis.* We have found that reduction of three genes, *MOSMO*, *POLR3E*, and *UQCRC2* cause severe craniofacial and cartilage defects. Additionally, we have found that reduction of *MOSMO* decreases axon length, and knockdown of *POLR3E and MOSMO* cause severe brain defects. Moreover, simultaneous knockdown of *MOSMO* with either *SETD5* or

POLR3E enhances several developmental phenotypes. Together, our results suggest that some genes within the 16p12.1 region are essential for proper embryonic development, providing further insight into how each of these genes may be contributing to the phenotypes associated with the 16p12.1 deletion.

P762/B781

Depletion of *Pxdn* in Mice Leads to Severely Disorganized Eye Structure in Homozygote in Contrast to Normal Visual Function in Heterozygote.

Y. Joe[1], H. Kim[1], K. Ham[1], S. Lee[1], H. Choi[1], H. Kim[2], H. Shin[3], H. Kim[3], K. Seo[3], Y. Cho[4], K. Nam[4], I. Kim[5]; [1]Department of Medical Lifesciences, College of Medicine, the Catholic University of Korea, Seoul, KOREA, REPUBLIC OF, [2]Department of Genetic Engineering Mouse, Macrogen Inc., Seoul, KOREA, REPUBLIC OF, [3]Department of Opthalmology, Yonsei Unieversity College of Medicine, Seoul, KOREA, REPUBLIC OF, [4]Severance Biomedical Science Institute,, Yonsei Unieversity College of Medicine, Seoul, KOREA, REPUBLIC OF, [5]Department of an atomy, College of Medicine, the Catholic University of Korea, Seoul, KOREA, REPUBLIC OF.

Peroxidasin (PXDN) is a unique peroxidase containing extracellular matrix motifs, and stabilizes collagen IV network by creating covalent sulfilimine crosslinks. PXDN gene knockout in *C. elegans* and *Drosophila* results in demise at embryonic and larval stages. PXDN mutations lead to severe eye disorders including microphthalmia, cataract, glaucoma and anterior segment dysgenesis in human and mice. To investigate whether PXDN deficiency affects morphological phenotype and organ development in mice, we generated *Pxdn* knockout mice by deletion of a sequence containing 5'UTR and exon1 of *Pxdn* gene using CRISPR/Cas9 system. Loss of both PXDN expression and collagen IV sulfilimine cross-links was detected only in the homozygous mice, but there were no changes detected between the heterozygous and wild type mice. Only the homozygous mice also showed completely closed eyelids or almost closed eyelids with small eyes, with no apparent external morphological defects in brain, heart, lung, spleen, kidney, and testis. In the histological analysis of eye tissues, the homozygous mice had extreme defects in eye development by showing no eyeballs or drastically disorganized eye structures, whereas the heterozygous mice showed normal eye structure. Visual function tests also revealed no obvious functional abnormalities in the eyes of the heterozygous mice compared with those of wild type mice. Thus, these results point to the essentiality of PXDN in eye development, and also indicate that single allele of *Pxdn* gene is sufficient for eye structure formation and normal visual function.

P763/B782

An Ectodermal Stem Cell Niche Drives Two-step Regeneration of Suicide Cells.

L. S. Babonis, M. Q. Martindale; University of Florida/Whitney Lab for Marine Bioscience, St. Augustine, FL.

Nematocytes, the "stinging" cells found in cnidarians (corals, jellyfish, etc), are defined by two important features: their novel organelle (the harpoon-containing nemato*cyst*) and their capacity for regeneration/replacement. Upon discharge, the contents of the nematocyst (harpoon, venom, etc) are forcefully expelled with nanosecond speed, tearing open the apical cell membrane, and necessitating cellular regeneration; thus, nematocytes have been termed single-use or "suicide" cells. We capitalized on this capacity for replacement to investigate the molecular regulation of organelle synthesis in this novel cell type. Nematocytes were discharged from the tentacle tips of the model sea anemone,

Nematostella vectensis, using an XYClone infrared laser ablation system. We show that complete replacement of the tentacle tip nematocytes occurs in under 24h and this process does not require cell proliferation. Using a specific marker of nematocyst synthesis, we show that wildtype animals regenerate nematocytes from a population of stem cells in the tentacle ectoderm. Initial synthesis of the post-golgi vacuole and proper trafficking of cnidocyte-specific proteins occurs during the first 24h after division from the nematocyte progenitor, giving rise to a population of partially differentiated nematocytes in the base of the tentacle tip. Final organellar maturation is cued upon discharge of the distal population of mature nematocytes. Treatment with hydroxyurea (HU), a reversible inhibitor of cell proliferation, blocked division of new nematocytes from their progenitors but had no effect on organellar maturation of the partially differentiated population. Treatment with DAPT, a gamma-secretase inhibitor which interferes with Notch signaling, inhibited final maturation but had no effect on the early steps of organelle synthesis. These results demonstrate a two-step process underlying nematocyte replacement and definitively identify, for the first time, a resident population of ectodermal stem cells in the tentacle of *N. vectensis* as the source of new nematocytes.

P764/B783

Transcriptome an alysis of Plasticity in the an terior-Posterior Neural Axis in *Xenopus Laevis* Embryos.

L. Lo, L. Bolkhovitinov, R. Cutler, C. Dong, M. Pownall, M. Saha; William & Mary, Williamsburg, VA.

While plasticity is an integral component of all living tissues, embryos display a profound degree of robustness. To analyze the limits of this robustness, we performed several different types of perturbations on the anterior-posterior neural axis of Xenopus laevis embryos. First, presumptive neural tissue was removed from a labeled donor, rotated 180° and heterologously transplanted into an unlabeled host embryo. Second, as a control for the rotation effects, tissue was removed from a labeled donor and heterologously transplanted into an unlabeled host embryo unrotated. Finally, as the sham may be slightly out of register when placed into a host embryo, an autologous (“selfie”) transplant was performed where the tissue was removed and then replaced back into the same embryo. All experiments were performed at both mid- and late gastrula stages, and raised to neurula or hatching stages. An initial series of experiments employed neural regional markers using in-situ hybridization as a molecular readout and analyzed in histological sections. All transplants healed and incorporated neighboring tissue. Moreover, all embryos showed profound patterning regulation except those with an inversion of their axis at the late gastrula stage. In order to determine the molecular basis of early developmental plasticity, we conducted a global gene expression RNA-Seq experiment on all embryo transplants and control. Our RNA-Seq data suggest a model in which aspects of early neural plasticity are associated with unique signatures of pathways and their associated genes. One set of pathways is enriched in all classes of transplants that heal and may mediate the ability of any type of transplant to incorporate and heal into neighboring tissue. This entails the upregulation of ubiquitination apoptosis and oxidative stress genes. Our transcriptome analysis reveals a second, distinct combination of pathways and genes that incorporate and heal, but also appropriately re-pattern the anterior-posterior axis. Maintaining plasticity in these transplants was correlated with expression of neuronal transcription factors, chromatin modifiers, Wnt signaling, calcium signaling, and pattern recognition molecules. In addition to identifying gene pathways involved in plasticity, the complexity and number of comparisons has necessitated a novel Baysesian approach to analysis of the RNA-Seq data.

Impaired *De Novo* Notochord Vacuole Formation Leads to Chordoma.

J. Garcia, J. Norman, M. Bagnat; Duke University, Durham, NC.

The notochord is a conserved axial component that serves as a structural scaffold. It is required for embryonic axis elongation and proper spine development. In zebrafish, it consists of a core of giant vacuolated cells surrounded by an epithelial-like sheath. Previous work showed that the fluid filled vacuole present in each vacuolated cell is a lysosome related organelle (LRO) that forms via a specific post-Golgi biosynthetic trafficking pathway and that vacuole integrity is important for notochord function. However, the machinery that controls *de novo* vacuole formation and integrity is not known. The sheath cells that surround the notochord are also capable of acquiring a vacuole and can restore notochord integrity upon mechanical damage. Once notochordal cells acquire a vacuole they become post-mitotic. In humans, notochordal cells that continue to divide outside of the intervertebral disc form chordomas, a poorly understood and aggressive type of tumor. Here, we have used a two-pronged transcriptomics and proteomics approach to identify proteins involved in *de novo* vacuole formation. We find that loss of a protein previously linked to LRO function leads to fragmentation of notochord vacuoles and impaired axis elongation. Interestingly, upon injury of the notochord, sheath cells fail to form a fully inflated vacuole and continue to grow outside of notochord boundaries, forming a tumor-like mass. This work identifies a protein important for notochord vacuole biogenesis in zebrafish and provides a new model to investigate chordoma formation.

P766/B785

Role of Neurofibromin 2 in Optic Fissure Closure and Retinal Pigment Epithelium Regeneration.

S. Ramirez[1], W. Sun[2], K. Spiller[1], S. Fuhrmann[1,2]; [1]Vanderbilt University, Nashville, TN, [2]Vanderbilt University Medical Center, Nashville, TN.

Purpose: Neurofibromin 2 (NF2), an activator of the Hippo pathway, regulates retinal pigment epithelium (RPE) cell fate and proliferation during eye development. One important process in development is optic fissure (OF) closure, as failure to properly close the OF is known to lead to coloboma. Furthermore, once the eye is fully developed, many cells types including the RPE, lose their potential to proliferate and regenerate. As the Hippo pathway is known to regulate development and cell proliferation, we focus on manipulating the Hippo pathway through NF2 in the adult RPE. Our study has two main goals: investigate the role of NF2 (1) during OF closure and occurrence of coloboma and (2) during RPE regeneration. **Methods:** We generated NF2 conditional knockout (CKO) embryos using the constitutive ocular *Rx3*-Cre*. Nf2*-CKO embryos were analyzed during OF closure for changes in cell proliferation, apoptosis, tissue patterning, apicobasal polarity, and cellular junctions. To study RPE regeneration, we generated *Nf2*-CKO mice using the RPE-specific, inducible tet-on *VMD2*-Cre*.* Mice were injected with sodium iodate, an injury model that mimics the course of age-related macular degeneration. Proliferation and regeneration were assessed by EdU incorporation and expression of OTX2 and RPE65 in the presumptive RPE layer 7.5 weeks post damage. **Results***: as* previously shown, *Nf2-CKO* embryos exhibit a coloboma with a narrow gap at E13.5, indicating a role for NF2 at late stages of OF closure. Early during OF closure, we observe a significant increase in EdU-labeled RPE cells, particularly in the ventral eye. Additionally, cell polarity and apoptosis appear largely maintained in the OF margins. Later during OF closure, the cell number in the ventral RPE is increased in *Nf2*-CKOs, and RPE markers persist in the OF margins. Currently, we are attempting to rescue OF closure. In adult

damaged RPE, our preliminary results show that there is a tendency for increased proliferation in *Nf2*-CKOs. Furthermore, there are more OTX2-positive cells in the presumptive RPE, and several show colocalization with EdU. This suggests potential de-novo production of RPE cells. Currently, we are analyzing markers for Hippo pathway components, cell junctions, and proliferation. **Conclusions:** Our results indicate a role for NF2 during OF closure, possibly by restricting the proliferation of RPE lining the OF margins. Our results also indicate a potential role for Hippo pathway modulation in regenerative proliferation of mature RPE. We hypothesize that NF2 acts through regulation of the Hippo/YAP-TAZ pathway during development and regeneration, consistent with previous studies showing a role for YAP-TAZ in regulating RPE fate.

P767/B786

Role of Calcium Activity during Early Neural Development.

S. Paudel, A. Rahman, E. Li, R. Nalamalapu, P. Kemper, M. S. Saha; College of William and Mary, WILLIAMSBURG, VA.

Influxes of calcium ions (Ca^{2+}) that occur at different amplitudes, frequencies, and cellular locations regulate a wide array of physiological processes. While calcium activity is indispensable for all aspects of embryonic development, particularly the developing nervous system, its dynamics during early embryonic development remain poorly understood. For instance, it is not known if there is a conserved or stereotypical pattern of calcium activity among embryos at a given stage of development of a given species. This is due to apparent irregular patterns of activity of individual cells, and a general lack of comprehensive analysis techniques at cellular level in *vivo*, where cells are constantly in a state of division, cell-cell intercalation, and migration. In this study, we aim to address this need and understand the spatial-temporal pattern of Ca^{2+} activity at a cellular level during vertebrate neural development. To this end, we devised a method to analyze the spatial-temporal pattern of calcium activity by constructing a composite neural plate. First, we monitored calcium activity of the *Xenopus laevis* neural plate using the genetically encoded calcium marker GCaMP6 and constructed a composite neural plate registering images onto a cellular-resolution grid. Secondly, the activity of individual cells was quantified using multiple analysis methods, including spike counting and entropy, and subsequently visualized as heatmaps in the composite neural plate. Our results, consistent with previous reports, show that neural plate stage embryos exhibit elevated calcium activity compared to late gastrula stages. In addition, our approach allows us to correlate calcium activity pattern with other cellular attributes, including levels of gene expression, cell size changes, and cell movements. We demonstrated the applicability of our method by correlating spatial-temporal pattern of calcium activity with expression pattern of a pan-neural marker gene, *Sox2*. Our preliminary results suggest calcium activity is significantly correlated with expression of *Sox2 in* specific neural regions. Moreover, our analysis demonstrates that while calcium waves occur in a stereotypical and consistent pattern among embryos at a given stage, spiking activity appears to be stochastic. Our approach of combining information on cellular attributes from different regions of a tissue into a composite template can be useful in facilitating spatial-temporal pattern analysis and therefore elucidating many cellular processes.

Embryogenesis

A Spatial Gradient of Cell Size Controls Genome Activation and Contributes to Vertebrate Early Development.

W. Qian, H. Chen, M. C. Good; University of Pennsylvania, Philadelphia, PA.

Zygotic genome activation (ZGA) is a process in embryonic cells that awakens and begins transcribing thousands of zygotic transcripts. ZGA marks the maternal-to-zygotic transition in which development switches from maternal to zygotic control. ZGA is essential for subsequent gastrulation and germ-layer specification, but how ZGA is triggered in vertebrate embryogenesis is poorly understood. Through metabolically labeling the nascent transcripts and wholemount imaging, our lab has found that in *Xenopus* blastula embryos, genome activation correlates with cells achieving a threshold size, due to blastomere division in the absence of growth. We identified a highly stereotyped spatial and temporal pattern of ZGA that occurs initially in small cells at animal pole and is delayed by two hours in cells of the vegetal pole. This spatiotemporal pattern tightly correlates with the gradient of cell sizes present in the blastula embryo. Although the gradient of cell sizes is evolutionally conserved in lamprey and amphibian species, less is known about its role on regulating the early vertebrate embryogenesis. The goal of our current study is to understand the biological significance of the gradient of cell sizes and the resulting pattern of transcriptional onset. To do so, we have developed an embryo temperature controller to manipulate the cell size gradient. It works by slowing down the division rate of fast dividing cells in the animal pole and speeding up division of slow dividing vegetal cells. By generating *Xenopus* blastula embryos with reversed cell size gradients, we found that the spatial pattern of ZGA was also reversed; genome activation occurred first in vegetal pole and was delayed in animal pole. Additionally, we observed delayed gastrulation and neurulation in embryos with altered cell size gradients. Portions of those embryos show defects on head and gut formation at tadpole stage, perhaps because their animal pole with transcriptional delay miss an important developmental window for responding to inductive signals which are originated in the vegetal pole. This work suggests that cell size gradient is critical to spatial patterns of ZGA and embryonic development.

P769/B788

How Cell Size Controls Genome Activation and Orchestrates Fate Decisions.

H. Chen[1], W. Qian[1], M. Good[1,2]; [1]Department of Cell and Developmental Biology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [2]Department of Bioengineering, School of Engineering and Applied Science, University of Pennsylvania, Philadelphia, PA.

A fundamental question is how embryonic cells induce genome activation and determine their fate in early embryo development. It has been proposed that genome activation is regulated by cell size through a titration mechanism dependent on DNA:cytoplasm ratio. Recently, using a model embryo that contains a gradient of cellular dimensions we demonstrated that the onset of genome activation is dependent on cells reaching a critical threshold size. By physically manipulating the size of embryos, we also demonstrated that reductions in cell size is sufficient to trigger premature genome activation in a dose-dependent fashion. However, it remains unknown what roles of cell size gradients are in early development and whether size thresholds for genome activation are conserved among vertebrate embryos. The origin of the cell size variation in *Xenopus* is due to distinct duration of the cell cycle in

distinct regions of the embryos. Therefore, to investigate the role of the cell size gradient we developed tools to control cell cycle timing in space in the embryo. In doing so, we were able to flatten and even reverse the cell size gradient. Intriguingly, by reversing the cell size gradient we found that the spatial pattern of genome activation was also reversed and that embryo development was also affected. We are investigating how alteration of spatial pattern of genome activation impacts tissue communication and cell fate regulation during gastrulation. Because cell size is thought to derepress transcriptional inhibition through titration of histone proteins we have quantified the spatial distribution of histones in *Xenopus* embryos and characterized a zebrafish mutant embryo that contains reduced levels of the core histones. We found that histone levels explain the size threshold for genome activation as well as cell fate decision. Finally, to address whether a cell size threshold for genome activation is a conserved feature of early embryo development we are imaging the onset of large-scale transcription in space and time in additional model systems, including blastula embryos from *X. tropicalis*, *D. rerio and* others. These studies highlight the functional importance of cell size as a regulatory parameter in genome activation and cell fate control.

P770/B789

Uncoupling Nuclear Size and Cell Size during Early Development: Perinuclear Endoplasmic Reticulum as a Limiting Factor for Nuclear Growth.

J. Sallé[1], R. N. Mukherjee[2], K. Nelson[2], S. Dmitrieff[1], J. Oakey[2], N. Minc[1], D. L. Levy[2]; [1]CNRS-Inst Jacques Monod, Paris, FRANCE, [2]University of Wyoming, Laramie, WY.

Nuclear size is a particularly well controlled aspect of subcellular morphology which plays a critical role in gene expression, early development and disease. The relationship between cell size and nuclear size established in the early 1900's supported the hypothesis of a nucleus-to-cell size scaling process. However, direct assays to test this scaling and the underlying mechanism were lacking. By monitoring nuclear dynamics in early sea urchin embryos, we found that nuclei undergo substantial growth in each interphase, reaching a maximal size prior to mitosis that declined steadily over the course of development as cell volume decreases. Strikingly, manipulations of cytoplasmic volume through multiple chemical or physical means showed that nuclear size can be uncoupled from cell size, suggesting that cytoplasmic volume is not a limiting factor for nuclear growth in the early embryo. Instead, we observed that the initial pool of perinuclear endoplasmic reticulum is partitioned at each division and progressively reduced. Our data support a new model in which perinuclear endoplasmic reticulum may serve as a limiting local membrane pool that determines subsequent nuclear growth kinetics, establishing size scaling throughout early development.

P771/B790

Blastoderm Formation in Crickets: a Crowding Mechanism Explains Nucleus Speed, Direction, and Division Timing.

S. Donoughe[1], J. Hoffmann[2], T. Nakamura[3], C. H. Rycroft[2,4], C. G. Extavour[2]; [1]University of Chicago, Chicago, IL, [2]Harvard University, Cambridge, MA, [3]National Institute for Basic Biology, Okazaki, JAPAN, [4]Lawrence Berkeley Laboratory, Berkeley, CA.

In most insects, development begins as a syncytium: that is, many nuclei divide and move within the single shared cytoplasm of the egg. It is essential for the nuclei to form a single layer—the blastoderm—which becomes the incipient embryo. A longstanding question is how these proliferating and migrating

nuclei self-organize into a single layer with the proper number, timing, and spatial arrangement. Recent work has shed new light on this puzzle in *Drosophila melanogaster*, showing that flies employ cytoplasmic flows and a mechanism that synchronizes divisions. Here we show that the cricket *Gryllus bimaculatus* has an altogether different solution to the problem. By live-imaging yolk and 3D-tracking nuclei in transgenic cricket embryos, we find that: (1) Cytoplasmic flows are unimportant for nucleus movement. (2) Division cycle period varies widely among coexisting nuclei, correlating with local nuclear density. (3) Nucleus speeds and orientations throughout blastoderm formation can be explained by a local crowding mechanism. Based on these findings, we present a simple geometric model that describes embryo-wide patterns of nucleus behavior. We use the model to predict what would happen to nucleus movements if an egg were to be physically constricted. Then we empirically test this prediction by constricting eggs, finding that the resulting nuclear behaviors are consistent with simulated embryos. Finally, we put the cricket and fruit fly data in the greater context of insect diversity. Across insects, syncytial eggs come in an enormous range of shapes and sizes. We hypothesize that over a macroevolutionary timescale, egg size and shape co-vary predictably with aspects of nucleus dynamics in early insect embryos.

Cell Lineage Specific Chiral Actomyosin Flows Drive Cellular Rearrangements in *C. Elegans* Development.

L. Pimpale[1], T. Middelkoop[1], A. Mietke[2], S. Grill[1]; [1]MPI-CBG, BIOTEC / TU - Dresden, Dresden, GERMANY, [2]MIT, Boston, MA.

Cells need to be positioned correctly during embryogenesis for achieving important processes like body axis formation and organ development. The mechanisms by which cells reposition in the early developing embryo are still not completely understood. Our lab recently showed that the gradient of myosin in the actomyosin cortex generates chiral rotatory flows and these flows are important for breaking left-right symmetry in a developing *C. elegans* embryo (Naganathan *et al.*, eLife 2014). Although it has been speculated that the process of spindle elongation play an important role in repositioning cells, we here test the hypothesis that chiral flows at the actomyosin cortex drive cellular repositioning during cell divisions. We show that chiral rotatory flows arise only in the somatic (AB) cell lineage, and that the presence of these flows correlates with cellular repositioning in the embryo. By combining active chiral fluid theory with experimentally measured myosin profiles we deliver a physical model explaining the emergence of chiral flows from myosin gradients during AB-lineage cell divisions. Using reverse genetics approach and temperature sensitive mutants we demonstrate that cellular rearrangements in the AB lineage are driven by chiral actomyosin flows. Thus, we conclude that chiral actomyosin flows drive cellular rearrangement in *C. elegans* early development.

Cell Ratcheting through the Sbf RabGEF Directs Force Balancing and Stepped Apical Constriction during *Drosophila*Gastrulation.

H. Miao, T. E. Vanderleest, C. E. Jewett, D. Loerke, T. J. Blankenship; University of Denver, Denver, CO.

During *Drosophila* gastrulation, the invagination of the prospective mesoderm is driven by the pulsed constriction of apical epithelial surfaces. Here, we address the mechanisms by which the irreversibility of pulsed events is achieved, while also permitting uniform epithelial behaviors to emerge. We utilize MSD-

based analyses to identify contractile steps and find that when a trafficking pathway initiated by Sbf is disrupted, contractile steps become reversible and AP anisotropies are lost. Sbf localizes to tubular, apical surfaces and associates with Rab35 where it promotes Rab GTP exchange. Interestingly, when *Sbf*/*Rab35* function is compromised, the apical plasma membrane in the ventral furrow become deeply convoluted and nonuniform cell behaviors begin to emerge. Consistent with this, Sbf/Rab35 appear to prefigure and organize the apical surface for efficient and balanced Myosin II network function. Finally, we show that Sbf/Rab35/CME direct plasma membrane to Rab11 endosomes through a dynamic interaction with Rab5 endosomes. These results suggest that periodic ratcheting events shift excess membrane from cell apices into endosomal pathways to permit re-shaping of actomyosin networks and the apical surface.

P774/B793

Post-transcriptional Regulation of Actin Remodeling Genes in the Early Embryo.

J. L. Song; University of Delaware, Newark, DE.

This study investigates the post-transcriptional regulation of actin remodeling genes by microRNA-31 (miR-31), using the sea urchin as a model. Our earlier work indicated that knockdown of miR-31 results in extra spicule rudiment, decreased spicule length, and defective skeletal patterning. In addition, miR-31 suppresses multiple transcription factors and effector genes within the skeletogenic gene regulatory network. To further identify the global function of miR-31, we conducted experiments with biotinylated miR-31 pull down assays and proteomic analyses of control and miR-31 knockdown embryos. Results identified Fascin and Rab35 as additional targets of miR-31. Fascin and Rab35 have been shown to interact with actin to remodel cytoskeletal structures. Results indicate that the spatial and temporal expression of miR-31 is enriched in the perinuclear region in non-dividing blastomeres and seems to associate with mitotic spindles and the chromatin in dividing blastomeres of the early embryo. miR-31 may regulate local translation of its targets to mediate mitosis in early cleavage embryos and regulate cell migration and motility during gastrulation. The results from this study serve as a paradigm for understanding post-transcriptional regulation of actin remodeling genes in ensuring proper cell divisions and cell motility in the early embryo.

Rho Gap RGA-8/ Rich1/SH3BP1 Promotes Myosin Enrichment in Migrating Embryonic Epidermis through CDC-42.

M. Soto[1], A. Wallace[2], S. Sasidharan[1], L. Cordova-Burgos[1], H. Raduwan[1]; [1]Rutgers - Robert Wood Johnson Med Sch, Piscataway, NJ, [2]Fairleigh Dickinson University, Teaneck, NJ.

CDC-42 regulation of non-muscle myosin/NMY-2 is required for polarity establishment in the one cell embryo of *C. elegans*. CDC-42 and NMY-2 continue to regulate polarity throughout embryogenesis, but their contribution to later events of epidermal morphogenesis are less understood. Our previous studies of epidermal enclosure revealed an essential requirement for the GTPase CED-10/Rac1 and its effector, the WAVE/Scar complex, in promoting the protrusions that drive enclosure through activation of the branch actin regulator Arp2/3. Our analysis here of RGA-8, a homolog of SH3BP1/Rich1/ARHGAP17/Nadrin, with BAR and Rho GAP motifs, demonstrates the contribution of CDC-42 and NMY-2 to two events of epidermal morphogenesis: ventral enclosure and elongation. Genetic and molecular data show RGA-8 regulates CDC-42, in a pathway involving the F-BAR proteins

TOCA-1 and TOCA-2, and the CDC-42 effector WSP-1. These proteins affect levels of myosin in the migrating epidermal cells during ventral enclosure, and the timing of enclosure. We propose TOCA proteins and RGA-8 fine-tune CDC-42 activity in the migrating cells, to promote myosin enrichment through effects on the myosin kinase MRCK-1. CDC-42 thus controls myosin during migrations and cell shape changes of epidermal morphogenesis.

Investigation of Wolf-hirschhorn Syndrome Associated Genes in *Xenopus Laevis* Embryos.

E. Snow, K. Montas, N. Burns, S. Kim, R. Cella, A. Mills, S. Lee, L. Lowery; Boston College, Chestnut Hill, MA.

Wolf-Hirschhorn Syndrome (WHS) is a neurodevelopmental disorder characterized by intellectual disabilities, craniofacial abnormalities, seizures, and defects in the development of the skeleton, heart, and urogenital tract. Previous genetic testing has shown that patients with WHS typically exhibit irregularities on the short arm of chromosome 4, such as deletions and microduplications. Most mutations occur in the first critical genomic region, containing the genes WHSC1 and WHSC2. Other WHS-associated genes such as TACC3 and LETM1 are located telomeric to this critical region. We have shown that the protein products of these four genes may be implicated in cranial neural crest cell (CNCC) migration and motility. Neural crest cells are multipotent stem cells found in vertebrates that originate along the neural tube early in development. These cells subsequently undergo a process called epithelial-to-mesenchymal transition (EMT) where they migrate long distances to form structures such as the face, jaw, peripheral nervous system, cartilage, and heart. Using *Xenopus laevis*, we determined that WHS-related genes are expressed in the neural tube and CNCC, leading us to investigate the effect of both single and combinatorial gene knockdown on craniofacial, pharyngeal arch, and cardiac morphology as well as on cartilage formation and CNCC migration. We found that the expression of all four genes is high in migrating neural crest cells and the neural tube, and that when these genes are knocked down, we see a significant defect in the migration of CNCC. We also are investigating how the knockdown of these genes leads to defects in cardiogenesis and specifically cardiac looping. We hypothesize that these defects arise as the direct result of errors in cell migration during cardiac development. This work will help to inform our understanding of the embryonic function of these genes and how their loss contributes to WHS.

P777/B796

Active Transport Allocates Lipid Droplets during Drosophila Embryogenesis, Facilitating Lipolysis and Punctual Development.

M. Kilwein, M. Welte; University of Rochester, Rochester, NY.

Lipid droplets (LDs) are fat storage organelles linked to numerous human diseases including obesity and diabetes. LDs are highly motile intracellularly. Our understanding of the role of this motility in LD functions is incomplete, but an emergent theme is that trafficking is crucial to proper LD metabolism. During early embryogenesis of multiple animal species, LDs undergo massive intracellular rearrangements. But, while it is known that embryonic LDs play roles in energy production, membrane synthesis, and the generation of signaling molecules, the role(s) of their motion is unclear. It is in *Drosophila* embryos that we have the greatest mechanistic understanding of how LD trafficking occurs. In these embryos, LDs are transported rapidly along microtubules, during the early cleavage and

blastoderm stages. This microtubule-based-transport utilizes both Dynein and Kinesin motor proteins, creating bidirectional transport. Embryos lacking the Klar protein have been previously shown to have severely impaired LD motility, including reduced motor-driven-forces propelling the LDs, massive reduction in the speed of individual LDs, and misallocation of LDs to the yolk cell post cleavage divisions. We find that embryos mutant in a seemingly unrelated LD protein Jabba display a similar misallocation of lipid droplets to the yolk cell, but via a completely different mechanism. Individual LDs in *Jabba* mutant embryos move at wild-type speeds, in stark contrast to *klar* mutants. However, most droplets are present in aggregates with each other or with glycogen granules. These aggregates are poor transport cargoes. Thus, Jabba promotes normal droplet allocation by preventing aggregation, while Klar ensures proper function of the microtubule-motor machinery. Both *klar and Jabba* mutant embryos fail to consume a portion of the misallocated LDs, leaving them with higher triglyceride levels relative to wild-type embryos at hatching. *Klar and Jabba* mutant embryos also take significantly longer to hatch than wild-type embryos, suggesting LD trafficking facilitates consumption and that failed consumption impairs development. Importantly, LD turnover and hatching times are, like LD allocation, due to the maternal functions of Jabba and Klar and do not reflect later, zygotic roles. We have titrated the amount of maternal Jabba protein provided to embryos and found a correlation between Jabba levels and delayed hatching. Preliminary data suggest that in the mutant embryos translation maybe inhibited through 4E-BP1/Thor upregulation, suggesting a cellular underpinning for the developmental stalling. To our knowledge, our data is the first to demonstrate organismal deficits caused by aberrant intracellular LD motility.

P778/B797

Translocation of Pyruvate Dehydrogenase Alpha Is Essential for Zygotic Genome Activation in Porcine Embryos.

W. Zhou, X. Cui; Chungbuk National University, Cheongju, KOREA, REPUBLIC OF.

Mammalian zygotic genome activation (ZGA) is critical for embryonic development, which appears after first several cleavages. Nuclear translocation of pyruvate dehydrogenase alpha 1(PDHA1) in mouse embryos during ZGA has been reported. To investigate the function of PDHA1 during ZGA in porcine embryos, a PDHA1 knockout (KO) parthenogenetic embryo model was generated by injection of Cas9 mRNA and sgRNAs. First, the nuclear translocation of PDHA1 gradually enhanced from two to late four-cell stage in porcine embryos. Second, results showed that level of PDHA1 and histone acetylation dropped significantly in PDHA1 KO group. Meanwhile, the 4-cell arrest rate significantly increased at 72 h after activation. Third, the LDH activity decreased and the ATP level increased in the PDHA1 KO group. Forth, the mRNA level of zygotic genes all dropped significantly in the PDHA1 KO group, however, overexpression of nuclear PDHA1 rescued ZGA. Fifth, histone acetylation levels significantly decreased when PDHA1 was targeted, which can be rescued fully or partially by overexpression of PDHA1. In conclusion, the nuclear translocation of PDHA1 promotes histone acetylation for zygotic genome activation in pigs.

P779/B798

Examining the Impact of Mitosis Duration on Embryo Development.

A. Allais[1], G. FitzHarris[2]; [1]CRCHUM-Université de Montréal, Montréal, QC, CANADA, [2]CRCHUM-Dept OBGYN Université de Montréal, Montréal, QC, CANADA.

The timing of cell divisions is highly variable in mammalian embryos, and is a potential indicator of embryo health in fertility clinics (termed morphokinetics). In somatic cells, extended mitosis can cause premature separation of sister chromatids, a phenomenon known as "cohesion fatigue" (CF), which could cause aneuploidy. Separately, a so-called mitotic clock checkpoint (MitClock) has been recently described wherein an extended duration of mitosis can cause a subsequent G1/S arrest. Here, I wish to determine whether cohesion fatigue can occur, and whether the MitClock operates, in mouse preimplantation embryos. We manipulated the duration of mitosis in two-cell stage mice embryos with the anaphase promoting complex inhibitor APCin. Live and fixed confocal imaging of the spindle, kinetochores, and DNA were performed. Mitosis prolongation causes an increase of spindle length and a time-dependent loss of chromosome alignment. 4% of all sister pairs had individualized by 6hours of mitotic arrest, and 66% by 24 hours. The loss of sister cohesion was preceded by an increase in inter-kinetochore distances from 0.59µm to 0.78µm ($p<0.0001$), consistent with CF. 24 hours mitosis prolongation in the presence of a spindle poison did not trigger CF, suggesting it is spindle-tension-dependent. Strikingly, live imaging revealed that 6 hours mitosis prolongation does not prevent subsequent embryo development, but doubled the frequency of micronuclei per embryo (4.5 vs 2.7), suggesting that CF leads to aneuploidy. In contrast, 24 hours mitotic arrest causes a potent cell cycle arrest in the subsequent interphase. Preliminary data suggests that this arrest may be dependent upon a critical level of cohesion fatigue.Moderately prolonged mitoses fail to activate a mitotic clock checkpoint in embryos, but lead to appreciable increase in cohesion fatigue and chromosome segregation defects. Our data allude that cohesion fatigue could be a previously unappreciated cause of mosaic aneuploidy in the mammalian embryo.

P780/B799

Bezafibrate Prevents Aging in in *Vitro*-matured Porcine Oocytes.

J. Kim, Y. Niu, X. Cui; Department of an imal Science, Chungbuk National University, Cheongju-si, KOREA, REPUBLIC OF.

Bezafibrate, a fibrate drug used as a lipid-lowering agent to treat hyperlipidaemia, is a pan-agonist of PPAR. It can prevent mitochondrial dysfunction and antioxidant system disturbance. It was also reported that bezafibrate upregulated PGC-1α and mitochondrial biogenesis. Postovulatory aging induces oxidative stress and mitochondrial damage. But the protective effect of bezafibrate on postovulatory aging in porcine oocytes is little known. In the present study, we investigated the effect of bezafibrate on the ability of against the progression of oocytes aging in *vitro* in porcine as well as the underlying its mechanisms. Different concentrations of bezafibrate (0, 25, 50, 100, 200 µM) was added to IVM medium during in vitro aging (IVA) and IVC medium after activation. Blastocyst formation and its quality were significantly increased in 50 µM bezafibrate addition group. Bezafibrate significantly alleviated IVA induced ROS production and increased GSH levels. However, the mitochondrial DNA copy number was not increased after bezafibrate treatment. Taken together, these results suggest that bezafibrate has beneficial effects against porcine postovulatory oocyte aging by its antioxidant property.

P781/B800

Elucidation of the Function of Mir-31 during Early Development.

C. Remsburg, 19716[1], K. Konrad[1], N. Stepicheva[2], J. Song[1]; [1]University of Delaware, Newark, DE, [2]University of Pittsburgh School of Medicine, Pittsburgh, PA.

MicroRNAs (miRNAs) are short, non-coding RNAs that repress translation of their target mRNAs. We previously identified that miR-31 is required for development and function of skeletogenic cells of the sea urchin embryo. In order to understand the global function of miR-31 in development, we injected biotinylated miR-31 into sea urchin zygotes to pull down its bound targets. RNA-sequencing was used to identify differentially pulled down transcripts between control and injected embryos in the blastula stage. Additionally, the early blastula proteome from zygotes injected with a scrambled control or miR-31 inhibitor was submitted for mass spectrometry to identify miR-31 targets. Our analysis of both data sets indicated that several potential miR-31 target genes encode proteins that interact with actin, including *Fascin*, *Nr1m3*, and *Rab35*. These results led to our hypothesis that miR-31 suppresses expression of actin remodeling genes to ensure proper formation of embryonic structures. Using a dual luciferase assay and site-directed mutagenesis, we found miR-31 to directly suppress *Fascin* and *Rab35*. Two isoforms of *Fascin* were identified, each with distinct expression patterns. Whole mount in *situ* hybridization revealed that *Fascin a* is expressed in non-skeletogenic mesodermal cells, and is increased during the blastula stage, when these cells are migrating throughout the embryo. In contrast, *Fascin B* is expressed in the ectoderm in the blastula stage, and the ectoderm and endoderm during the gastrula stage. Additionally, *Fascin B, Rab35* and miR-31 are expressed in the midzone between dividing nuclei and enriched perinuclearly in non-dividing blastomeres of cleavage stage embryos. Immunolabeling revealed that Fascin localizes to the cortex of the egg and is ubiquitously expressed with enrichment in skeletogenic cells during the cleavage stage, in the mid-gut, and ciliary band of the larval stage. Preliminary results indicated that inhibition of miR-31 results in Fascin protein enrichment at the perinuclear area of blastomeres of the cleavage stage embryos, consistent with miR-31's perinuclear localization as a translational suppressor of *Fascin*. Furthermore, knockdown of *Fascin* and *Rab35* revealed gastrulation defects, consistent with the wide gut phenotype previously observed in miR-31 knockdown embryos in support of our hypothesis. Our results revealed a potential regulatory role of miR-31, Fascin, and Rab35 in early development. By identifying the targets of miR-31 and the function of its targets, our results will enable us to develop a deeper understanding of how miR-31 regulates early development and embryonic structure formation.

Blastocyst Injection Rescues the Postnatal Growth Retardation in Chimeric Mouse.

T. Nishimura[1,2], J. Bhadury[1,3], F. P. Suchy[1], C. Charlesworth[1], H. Nakauchi[1,2]; [1]Institute for Stem Cell Biology and Regenerative Medicine, Stanford University, STANFORD, CA, [2]The Institute of Medical Science, the University of Tokyo, Tokyo, JAPAN, [3]Department of Clinical Chemistry and Transfusion Medicine, the Institute of Biomedicine, Sahlgrenska University Hospital, Gothenburg, SWEDEN.

While an interspecies chimeric fetus (mouse-rat) develops to a birth, its biological phenotype, such as body size, is mostly inherited from host species. Generation of donor dominant interspecies chimera would help us to understand the mechanism determining the species itself. We have recently demonstrated that high contribution of donor cells into an interspecies fetus causes an embryonic lethal, which leads to generating a low chimeric animal having the same biological features as host

species. This “xenogeneic barrier” limiting interspecies embryonic chimerism prevents a high chimeric animal from being born. Growth hormone (Gh) is one of the critical factors for postnatal body growth, which stimulates cell proliferation and metabolism. To overcome this barrier, here we aim to develop a new system which increases postnatal donor chimerism by knocking out Gh receptor (Ghr) in host embryos. **Methods**: GFP-labeled mouse embryonic stem cells (mESCs) derived from C57L/B6 strain, were prepared for blastocyst injection in basic mESCs culture condition. The Ghr gene in a mouse embryo was knocked out by electroporation with Cas9/gRNA ribonucleoprotein complexes. The mESCs were injected into wild type (WT) or Ghr knockout (Ghr KO) mouse blastocyst and then the chimeric embryos were transferred to a pseudopregnant female mouse. The body size and blood chimerism in the chimeras derived from these embryos were analyzed at several time points by flow cytometry. The chimerism in each organ was analyzed by digital PCR. **Results and Discussion:** the knockout efficiency of Ghr gene in a host embryo was over 80 % and Ghr KO mouse showed postnatal growth retardation. Compared to conventional genome editing methods, our method was rapid (over 6 months vs. 3weeks) and much efficient (25% vs. 80%). Next, we found that high contribution of WT cells into Ghr KO chimera rescued growth retardation. Besides, its blood chimerism was maintained postnatally, while WT and low chimeric Ghr KO chimeras decreased. These results indicate that the chimerism would be a critical factor determining the phenotype of chimera. The chimerism in the thymus was significantly higher in Ghr KO chimera than in WT chimeras. This result reveals that Ghr KO cells have a disadvantage in thymus niche. However, it is still unclear what factor is related to this disadvantage. **Conclusion:** We have demonstrated that Ghr KO in a host embryo provides donor cell-advantageous environment in chimera. By using this system, we would like to further generate an interspecies chimera having the same biological feature as donor species.

P783/B802

***Axin1* and *Axin2* Genes Determine Pluripotent Versus Extraembryonic Mesoderm Cell Fates in the Post-implantation Mouse Embryo.**

R. Hernandez-Martinez, K. V. An derson; Memorial Sloan Kettering Cancer Center, New York, NY.

The three germ layers of the mouse embryo, ectoderm, endoderm and mesoderm, are generated from the pluripotent epiblast during gastrulation and go on to form the differentiated tissues of the animal. The extraembryonic mesoderm (EEM) cell population originates in the epiblast and gives rise to tissues that facilitate maternal-embryo interaction, but the signals that regulate EEM differentiation are not well understood. In the course of studies on Axin, a negative regulator of the WNT/β-catenin pathway, we uncovered a new role for WNT signaling in the determination of extraembryonic mesodermal (EEM) cell fate. It has long been known that *Axin1* null mutant embryos exhibit partial or complete duplication of the body axis. We found that although *Axin2* single mutants are viable, *Axin1/Axin2* double mutant embryos arrest before gastrulation and the entire mutant epiblast initiates a premature epithelial-to-mesenchymal transition (EMT) and acquires an EEM identity. The expression of core pluripotency transcription factors such as Oct4, Nanog and Sox2 is downregulated in the epiblast in *Axin1/Axin2* double mutants. Embryos that lack Smad2, a mediator of signaling by Nodal recapitulate many of the defects seen in *Axin1/Axin2* double mutant embryos, including changes in pluripotency gene expression and the differentiation of the epiblast into mesoderm. This suggests that Nodal/Smad2 activation preserves the pluripotency of the mouse embryo epiblast. Epiblast-Like Cells (EpiLC) lacking *Axin1/2* genes recapitulate the defects of loss of pluripotency and premature mesoderm differentiation, facilitating the use of Nodal and Wnt pharmacological inhibitors to test the roles of these two signaling

pathways. We propose that Axin proteins regulate an instructive response of Wnt signals in the epiblast to decide between pluripotent and EEM cell fate; by contrast, Nodal signals are permissive and preserve the pluripotency and proper patterning of the epiblast. These findings define a new regulatory circuit that integrates graded WNT and Nodal/Smad2 signals to control the switch between pluripotency and EEM differentiation.

P784/B803

Distinct Prepatterns of RhoA Activity and F-actin Levels Promote Tissue Folding.

M. Denk-Lobnig, N. C. Heer, A. C. Martin; MIT, Cambridge, MA.

The emergence of organism and organ shape during development requires coordinated forces that change tissue shape. One way that planar epithelia are sculpted is through bending/folding of the sheet to generate curvature, forming structures like invaginations or tubes. How epithelial sheets regulate curvature is unknown. We used the invagination of the *Drosophila* presumptive mesoderm to determine that distinct multicellular patterns of RhoA activation and F-actin levels generate proper tissue curvature. First, we showed that mechanical connections between cells are not required for graded myosin activation, suggesting that a prepattern of transcriptional activation establishes the myosin activation gradient. Second, we showed a gradient in RhoA activity that is established by proper balance between a GTPase activating protein, C-GAP and a Guanine Nucleotide Exchange factor, RhoGEF2, which establishes proper tissue curvature. Finally, we show that cells that stretch in the marginal mesoderm exhibit depleted F-actin levels compared to ventral midline cells and the ectoderm, suggesting that a zone of F-actin depletion allows cell stretching at the tissue margin to promote apical constriction and folding at the ventral midline. Thus, transcriptional patterning of contractility and F-actin levels across a tissue determines tissue curvature, which could explain the diverse shapes in different folding processes throughout development.

P785/B804

Mechanosensation of Tight Junctions by Zo-1 Phase Separation and Flow.

C. Schwayer[1], K. Pranjic-Ferscha[1], A. Schauer[1], S. Shami Pour[1], M. Balda[2], M. Tada[3], K. Matter[2], C. Heisenberg[1]; [1]Institute of Science and Technology Austria (IST Austria), Klosterneuburg, AUSTRIA, [2]Institute of Ophthalmology, University College London, London, UNITED KINGDOM, [3]Department of Cell and Developmental Biology, University College London, London, UNITED KINGDOM.

Cell-cell junctions respond to mechanical forces by changing their organization and function. Tension-dependent conformational changes of junctional proteins are thought to underlie this junctional mechanosensitivity. Here we show that in the gastrulating zebrafish embryo, tight junctions (TJ) mechanosensitivity is mediated by actomyosin-driven flow of phase separated Zonula occludens-1 (ZO-1) clusters. We found that ZO-1 junctional accumulation at the contact between the Enveloping Layer (EVL) and the Yolk Syncytial Layer (YSL) closely scales with actomyosin tension. Actomyosin tension triggers ZO-1 junctional accumulation by driving retrograde actomyosin flow within the YSL that transport non-junctional ZO-1 clusters towards the TJ. Non-junctional ZO-1 clusters form by phase separation, and their effective formation is dependent on the actin binding region (ABR) within the C-terminus of ZO-1. If the non-junctional ZO-1 pool is absent, TJ lose their mechanosensitivity, and, consequently, EVL-YSL movement is impaired. Thus, phase separation and flow of non-junctional ZO-1 confer mechanosensitivity to TJ.

P786/B805

Acute Rho1 Activation Reveals That Ventral Epithelial Cells of the *Drosophila* Embryo Are Specifically Predisposed for Coordinated an isotropic Constriction during Gastrulation.

A. Rich, R. Fehon, M. Glotzer; University of Chicago, Chicago, IL.

Many morphogenetic events, including convergent extension and tube formation, require modulation of the actomyosin cytoskeleton. Ventral furrow formation in Drosophila embryos is one such morphogenetic event; it results when extracellular signals activate two transcription factors, Snail and Twist, in a subset of ventral epithelial cells. These regulators then drive the expression of multiple proteins which ultimately induce Rho1 activation, apical constriction, and invagination of cells into the embryo. These apical constrictions are anisotropic and appear coordinated, but the basis for this anisotropy and coordination is unknown. To address this and related questions, we utilized optogenetics to control Rho1 activity in the embryo. Acute Rho1 activation at the onset of gastrulation induces ectopic invaginations in both the dorsal and ventral embryonic epithelium. Rho1 activation induces apical constriction in both dorsal and ventral cells, but ventral cell constriction is stronger and more anisotropic. Strikingly, ectopic Rho1 activation induces non-cell autonomous deformations outside the activation zone only in the ventral epithelium. Thus, we demonstrate that ventral cells are specifically predisposed to respond to Rho1 activation with anisotropic and coordinated deformations. To identify the factors required for ventral cell specific behavior, we analyzed acute Rho1 activation in embryos deficient in factors required for ventral furrowing. Ventral cells depleted of RhoGEF2 exhibit anisotropic apical constriction, suggesting a molecular specialization of ventral cells beyond their ability to activate high levels of Rho1. Ventral cells lacking Twist exhibit weaker and less anisotropic apical constrictions, indicating a previously unknown role of Twist. Unlike wildtype or twist embryos, Rho1-induced deformations persist in RhoGEF2-depleted embryos. Collectively, our results demonstrate that while Rho1 is sufficient to initiate invagination throughout the embryonic epidermis, the individual cell shape changes accompanying these invaginations differ between dorsal and ventral cells. Additionally, ventral cells specifically can propagate the response to Rho1 activation outside of the zone of optogenetic activation. Experiments are in progress to identify the factors required for these ventral specific behaviors.

P788/B807

A *Drosophila* Deficiency Screen for Genes on Chromosome 2L Involved in Dorsal Closure Using a Live Imaging Approach.

S. M. Fogerson, R. D. Mortensen, R. P. Moore, H. Y. Chiou, N. K. Prabhu, A. H. Wei, D. Tsai, O. Jadi, K. An doh Baidoo, D. P. Kiehart; Duke University, Durham, NC.

Cell sheet morphogenesis is essential for metazoan development and homeostasis of animal form - it contributes to developmental milestones including gastrulation, neural tube closure, heart and palate formation as well as tissue maintenance in wound healing. Dorsal closure occurs during *Drosophila* embryogenesis and has emerged as a model for cell sheet morphogenesis throughout phylogeny. Closure is a remarkably robust process where conserved gene expression and signaling cascades are coordinated to regulate the cellular machines that drive closure. Many of the ~140 known 'dorsal closure genes' were identified in screens by scoring for a terminal, dorsal open cuticle phenotype. Thus, key genes that contribute to the kinematics and dynamics of closure may not have been identified.

Here, we extend our previous study of the right arm of the 2nd chromosome (2R, Mortensen *et al*. 2018 G3: Genes|Genomes|Genetics 8:2361) to the left arm of the 2nd chromosome (2L). We used the Bloomington 2L deficiency kit, a set of large deletions, which collectively remove 98.9% of the genes on 2L to identify 'dorsal closure deficiencies'. Through two crosses, we unambiguously identify embryos homozygous for each deficiency and time-lapse image cell shapes for the duration of closure. Confocal images of GFP-cadherin are analyzed for defects in cell shapes and tissue movements. We have successfully screened 96.1% of the genes on 2L and identified embryos homozygous for 46 deficiencies with notable, diverse defects in closure. Of these, 26 have no known dorsal closure gene removed by the deficiency region. These include defects in cell shape, canthus formation and tissue dynamics. As with our previous analysis of the 2R, we anticipate further analysis of these and other 2L deficiencies will lead to the identification of novel 'dorsal closure genes' (for example *pimples* accounts for dorsal closure defects seen in embryos homozygous for Df(2L)63). We expect to identify links between pathways and structures already known to coordinate various aspects of closure as well as new processes and pathways that contribute to closure. Grant Support: R35GM127059 to DPK; NSF-DGE 1644868 to SMF; T32 GM007184 to SMF, RPM and RDM.

TAF13 Is Essential for Early Mammalian Development.

S. Phillips, J. Mager; University of Massachusetts Amherst, Amherst, MA.

TATA-Binding Protein Associated Factor 13 (TAF13) is one component of the transcription pre-initiation complex (PIC). The transcription PIC is essential for initiation of the transcription of protein-coding genes. The transcription PIC is made up of the RNA polymerase II (RNA pol II) and six general transcription factors TFIIA, TFIIB, TFIID, TFIIE, TFIIF, and TFIIH. The general transcription factor TFIID is made up of TATA-Binding Protein (TBP) and 13 highly conserved TBP-Associated Factors (TAFs). We have undertaken a systemic characterization of TAF13 homozygous mutants in order to determine the developmental and molecular phenotype in embryos lacking functional TAF13. Breeding TAF13 +/- mice does not yield TAF13 -/- pups, indicating that the TAF13 -/- embryos are dying in utero. Our studies reveal that TAF13 -/- embryos are developmentally delayed compared to their littermates by day 7.5 of embryonic development (E7.5) and fail to initiate gastrulation. We also show that key developmental transcription factor expression is absent in these mutant embryos, showing for the first time that TAF13 is required for TFIID/PIC function in vivo.

P790/B809

Stretch Forces Activate Mechanically-gated Calcium Channels Elevating Calcium and Nitric Oxide in the Ectoderm Germ Layer of the Chicken Embryo.

A. Martin; San Francisco State University, San Francisco, CA.

Early embryo development for myogenesis requires morphogen inductive signaling over the paraxial mesoderm that results in somite formation, its compartmentalization, and myotome and sclerotome tissue formation. While morphogens have been well studied in embryonic development, other molecular regulators have not, including the pleiotropic signaling molecule, nitric oxide (NO). We previously reported that calcium (Ca2+) and NO signals are co-localized in the ectoderm layer over the embryo midline and somites creating a pattern to correlate with nascent myotome formation. However, how these ectoderm signals are initiated is unknown. We propose that rapid embryonic growth and

development are possible physical activators of Ca2+ and NO signals through a strengthening mechanical stretch force on the ectoderm layer due to a rapidly growing neural tube at the cranial embryo location. To investigate mechanical force activation of ectoderm Ca2+ and NO, we fabricated a custom made “rake” device to control tension by medial-lateral stretching of the area opaca in HH10 staged embryos. Live-imaging through spinning disc confocal microscopy was used on embryos labeled for Ca2+ using calbryte™520 and NO using DAF-2. Our results show pulls of the area opaca of 0.5 mm resulted in 2-fold elevations of ectoderm Ca2+ within 3-seconds and a return to Ca2+ baseline levels at the embryo midline and over cranial located somites. To determine if mechanically-gated Ca2+ channels produce the Ca2+ rise on applied tension, whole embryos were treated with 250 µM of gadolinium chloride (GdCl3) that inhibited Ca2+ elevation to an only slight increase. Furthermore, embryos in 1mM EGTA to deplete medium Ca2+ levels were stretched and produced no Ca2+ rise in the ectoderm. However, a subsequent rise in NO could not be produced with a momentary rise of ectoderm Ca2+ under our stretch conditions. In contrast, ectoderm isolated as sheets of cells, cultured for 1 day on stretchable PDMS membrane, could produce a rise in Ca2+ and a later increase in NO over 30 minutes of stretch. In conclusion, the ectoderm under stretch activates opening of a mechanical-gated Ca2+ channel that can produce a NO elevation in culture conditions. We anticipate NO to elevate as well in whole embryos with longer times of Ca2+ elevation involving activation of other Ca2+ channels, like the L-type channels. **NSF STC CCC: 1548297**

Tristetraprolin (ttp) Expression Is Required for Maintenance of the Mammary Progenitor Cell Population.

M. N. Stedile[1], I. Beckerman[1], M. V. Goddio[1], L. Pérez Cuervo[1], M. García Solá[1], M. V. Medina[1], A. Raimondi[1], O. Coso[1,2], E. C. Kordon[1,3]; [1]Instituto de Fisiología, Biología Molecular y Neurociencias (IFIBYNE), Buenos Aires, ARGENTINA, [2]Departamento de Fisiología, Biología Molecular y Celular, Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, Buenos Aires, ARGENTINA, [3]Departamento de Química Biológica, Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, Buenos Aires, ARGENTINA.

Messenger RNA (mRNA) stability is regulated mainly by proteins that bind sequences enriched in adenine and uracil in their 3´untranslated regions, called collectively AU-binding proteins (AUBPs). Tristetraprolin (TTP) is an AUBP that promotes mRNA degradation of proteins involved in inflammation, proliferation and tumor invasiveness. We have previously reported that TTP expression is down-regulated in breast cancer compared to normal mammary gland, where TTP reaches its highest levels during lactation. In addition, bitransgenic females WAP-Cre x $TTP^{fl/fl}$ mice (named MG TTP-KO), showed that reduction of TTP levels in the lactating mammary gland resulted in premature involution associated to the increase of TNFα, IL-6 and LIF expression, STAT3 activation and massive cell death. Therefore, we concluded that TTP expression in the mammary epithelium is required for lactation maintenance. Then, as it has been reported that WAP-expressing cells behave as a pregnancy-induced mammary progenitor subpopulation and analysis of RNA-seq data indicates that TTP is up-regulated in mammary progenitor cells, our next goal was to determine whether expression of this AUBP is relevant for the maintenance of the mammary stem cell compartment. Our results showed that upon successive pregnancies MG TTP-KO mice exhibited underdeveloped lactating glands that also presented decreased pre-neoplastic lesions

when crossbred with WAP-Cre/RasG12D mice. Moreover, mammary glands from total TTP-KO mice displayed underdeveloped ductal network upon transplantation into syngeneic mammary cleared fat pads. This suggested that diminished expression of TTP in the mammary progenitor compartment caused impairment of mammary gland development and differentiation. To verify this hypothesis, we generated TTP knockdown cells (TTP-KD) by stable transfection of stem-like HC11 mammary epithelial cells with specific TTP-shRNA constructs. Interestingly, these cells exhibited impaired survival rates (by MTS analysis), increased apoptosis (by TUNEL), and induction of pro-apoptotic proteins (by Western blot, WB). Besides, TTP-KD cells also displayed high expression of inflammatory cytokines (analyzed by RT-qPCR), increased levels of STAT3 and P-STAT3 as well as p65/RelA and p38 phosphorylation, but inhibition of ERK 1/2 activation (studied by WB and treatment with specific inhibitors). Importantly, the TTP-KD cells revealed a substantial decreased capacity to form mammospheres in 3D culture and to repopulate cleared fat pads of virgin BALB/c female mice. Taking together, our results indicate that TTP expression is required for mammary progenitor cell survival by preventing spontaneous pro-inflammatory and stress-associated events, which are able to induce mammary stem cell death.

Comparative Single Cell Transcriptomic an alyses Reveal Molecular Similarities and Differences of Stem Cell Biology during Mammary Gland Development and Regeneration.

T. Zhou, P. Lu; ShanghaiTech University, Shanghai, CHINA.

A central goal in vertebrate stem cell biology is to understand the molecular basis of crosstalk between stem cells and their niche microenvironment during development, regeneration, and pathology. Here, we have used single cell transcriptomics and genetic manipulations to interrogate stem cell - niche interactions during differentiation and morphogenesis at various phases of mammary gland development and regeneration. We found that, during mammary gland regeneration, adult stem cells are “reprogrammed” to an embryonic progenitor state, followed by subsequent differentiation stages similar to those during development. This has allowed by to identify candidate genes and signaling pathways that regulate critical stages of mammary stem cell differentiation. Furthermore, we found that FGF signaling not only plays an essential role between stem cell and stromal microenvironment, it is also essential for luminal and basal interactions during differentiation and epithelial branching. These data thus highlight the complexity of the cellular components of stem and niche cells and underscore the pluripotent roles of FGF signaling in regulating their interactions.

Defects in Neural Precursor Proliferation and Abnormal *Asxl1* Expression as a Result of Mutations in *Hcfc1* Ortholog Induce Hypoactive Behavior in Zebrafish Model of *Cblx* Syndrome.

V. Castro, J. Reyes, A. Quintana; University of Texas at El Paso, El Paso, TX.

Methylmalonic acidemia and homocysteinemia, clbX type (*cblX*) (309541) is rare multiple congenital anomaly syndrome caused by mutations in the *HCFC1* gene which encodes for a transcriptional cofactor. The neurological phenotypes associated with *cblX* are profound, yet the mechanisms by which mutations in *HCFC1* cause such deficits remain unknown. This developmental disease is characterized by severe neurological impairment, indicating a function for HCFC1 during normal brain development. Previous studies suggest that HCFC1 regulates neural precursor cell (NPC) proliferation and differentiation. However, HCFC1 regulates a diverse array of target genes and has been shown to bind to

the promoters of more than 5000 unique downstream target genes. Consequently, the molecular mechanisms by which HCFC1 regulates NPC proliferation and differentiation are complex. Therefore, we hypothesize that HCFC1 is a master transcriptional regulator of NPC function. To test this, we have developed a zebrafish harboring a germline mutation in *hcfc1a*, a zebrafish ortholog of *HCFC1*. Using this platform, we discovered that *hcfc1a* regulates the proliferative state of NPCs in *vivo* by mediating the developmental expression of *asxl1*, a polycomb transcription factor. Furthermore, we found that the additional NPCs that are generated continue through the differentiation pathway and produce excess neurons and glia. Importantly, these excess differentiated cells were associated with hypo-locomotive behavioral deficits. Collectively, our data provides a novel mechanistic insight into the transcriptional program modulating NPC proliferation, brain development and motor function.

P794/B813

Notch Signaling Regulates Neural Stem Cell Entry into Quiescence in *Drosophila*.

C. Sood, S. E. Siegrist; University of Virginia, Charlottesville, VA.

During development, neural stem cells divide in a symmetric manner to expand the stem cell pool and in an asymmetric manner to generate different types of progeny. Neural stem cells also switch between periods of quiescence versus proliferation in response to both intrinsic and extrinsic factors. One important extrinsic factor regulating proliferation decisions is the availability of nutrients because dietary nutrients provide the building blocks necessary to fuel the cell divisions. We are interested in understanding how quiescence versus proliferation decisions are controlled during development. We use *Drosophila* as a model system because of the availability of genetic tools and because the population of neural stem cells, known as neuroblasts in *Drosophila*, is relatively simple and defined. Most neuroblasts in the central brain enter and exit quiescence in a nutrient-dependent and PI3-kinase regulated manner. To better understand how neural stem cell proliferation decisions are regulated we carried out a large-scale RNAi screen. From this screen, we identified components of the Notch signaling pathway. Notch signaling is an evolutionarily conserved juxtacrine cell signaling pathway that in the *Drosophila* central brain allows for cross-talk between both neuroblasts and their daughters and between neuroblasts and their glial niche. To activate Notch signaling, Notch receptor binds to its ligand, Delta. Here we investigate how Notch/Delta signaling regulates neuroblast entry and exit from quiescence during the embryonic to larval transition. We found that Notch signaling in neuroblasts is activated in a nutrient-dependent manner and once on, it remains on in a nutrient-independent manner. Next, we used RNAi to knockdown Notch signaling in neuroblasts. After 24hrs of feeding, we found no difference in neuroblast proliferation compared to control. However, in freshly hatched larvae before animal feeding, we found ectopic neuroblast proliferation when Notch or Delta was knocked down. This suggests that Notch/Delta could be required for neuroblast entry into quiescence. To investigate this possibility, we assayed neuroblast proliferation prior to neuroblast entry into quiescence. We found that neuroblast proliferation continued longer when Notch or Delta was knocked down in neuroblasts compared to control. Next, we assayed the expression of Notch signaling components as neuroblasts entered into quiescence. We found that Notch and Delta expression was downregulated as neuroblasts enter quiescence. We conclude that Notch signaling is required for neuroblast entry into quiescence and that active Notch signaling correlates with neuroblast proliferation.

P795/B814

Understanding the Role of *LAMB4* in the Neurodegenerative Disease Familial Dysautonomia.

K. Saito-Diaz, J. R. Street, N. Zeltner; University of Georgia, Athens, GA.

The genetic childhood disorder Familial Dysautonomia (FD) is a particularly devastating disease of the peripheral nervous system (PNS). Patients present with a range of symptom severity; however, the mechanism behind this phenomenon is unknown. Patients with FD harbor a missense mutation in exon 19 of the gene *IKBKAP*, resulting in low IKAP protein levels in PNS neurons, which causes impaired development and survival of sensory and autonomic neurons. Although FD is a monogenetic disease, patients exhibit a wide range of disease severity, such as mildly or severely decreased ability to sense pain and different frequency of dysautonomic crisis. The recently established mouse model for FD does not completely recapitulate the human disorder, particularly with respect to severity differences. Thus, its predictive value is limited. Similarly, due to lack of access to cells targeted by the disease (i.e., sensory neurons), the molecular knowledge we have of FD pathophysiology is limited and may not translate to what occurs in physiological conditions. Therefore, the mechanism underlying the causes of FD severity is not understood. Human pluripotent stem cells represent a powerful platform to study FD in a disease-relevant and tissue-specific context. We previously used induced pluripotent stem cells (iPSCs) derived from FD patients to model disease severity. We found that restoring the mutation in *IKBKAP* did not rescue all severe FD phenotypes, suggesting that other factors might be involved in FD severity. Agreeing with this, we found that FD patients with severe symptoms harbor a mutation in *LAMB4* in addition to *IKBKAP*, that is absent in mild FD patients. Thus, I hypothesize that *LAMB4* is necessary for normal PNS development and loss of wild type *LAMB4* exacerbates the symptoms to severe FD in patients. Agreeing with this, I found that SNs from patients with severe FD exhibit low levels of lamninin-β4 (the product of *LAMB4*) compared to healthy controls. The exact function of *LAMB4* is unknown. However, *LAMB4* mutations have been associated with the enteric neuropathy Diverticulitis, supporting my hypothesis that *LAMB4* plays a role in neurodevelopment and in diseases of the PNS. My studies will provide insight on the role of *LAMB4* during development of the PNS. Moreover, it will uncover the mechanism behind the symptom severity observed in FD, providing potential new approaches for the development of novel therapeutics.

Netrin-1 Synthesized in Satellite Cells Isolated from Fast-twitch Muscles May Promote Fast Myofiber-type Commitment.

T. Suzuki[1], A. Mori[1], E. Ichimura[1], Y. Nishi[1], R. Arimatsu[1], T. Maeno[1], K. Kobayashi[1], K. Ojima[2], R. Tatsumi[3], T. Nishimura[1]; [1]Research Faculty of Agriculture, Graduate School of Agriculture, Hokkaido University, Sapporo, JAPAN, [2]Animal Products Research Division, Institute of Livestock and Grassland Science, NARO, Tsukuba, JAPAN, [3]Department of an imal & Marine Bioresource Sciences, Graduate School of Agriculture, Kyushu University, Fukuoka, JAPAN.

Resident myogenic stem cells, satellite cells, are indispensable for successful regeneration and hypertrophy on skeletal muscle fibers (myofibers). We currently focus on a novel role of satellite cells in the myofiber-type regulation. Myofibers can be classified into slow- or fast-twitch muscle based on colors, contractile properties and metabolisms. Our previous studies showed that satellite cells prepared from soleus muscle (slow-myofiber abundant) synthesize and secrete larger amount of semaphorin 3A (Sema3A, a multi-functional protein originally found as a neural chemorepellent) than extensor

digitorum longus (EDL; fast-fiber abundant) at myogenic differentiation phase (Suzuki et al. 2013). The subsequent study demonstrated that Sema3A impacts the formation of slow-twitch myotube through the cell-membrane receptor complex neuropilin2/plexinA3 signaling pathway at the early-differentiation phase after muscle injury(Tatsumi et al. 2017). In contrast to this Sema3A-driven mechanism, there are few knowledges about regulatory mechanisms for “fast-twitchmyotube commitment” by a secretory protein(s) from satellite cells. In this study, we hypothesized the function of Netrin families (Netrin-1, 3 and 4) that may contribute to fast-twitch myotube formation since their physiological significances are known to compete with Sema3A in neurogenesis and osteogenesis. To evaluate this hypothesis, we examined whether Netrins impact fast-twitch myotube generation through the expression profiles of Netrin families in primary cultures of satellite cells and knock-down by specific siRNAs transfection with RNA interference technique. We revealed that Netrin-1 and 4 were significantly up-regulated like a Sema3A expression pattern during myogenic differentiation phase. Subsequently, we compared the expression levels of Netrin subtypes and receptors between soleus- and EDL-derived satellite cells; there were no significant differences in expression levels of Netrin-3, 4 and Netrin’s cell-membrane receptors (neogenin, BOC, CDO, Unc5B and 5C), while satellite cells from EDL expressed higher levels of Netrin-1 than those from soleus. Moreover, Netrin-1 knock-down inhibit myotubes formation by significantly diminishing the expression level of fast-type myosin heavy chain (especially in type IIb). These findings suggest that Netrin-1 synthesized in EDL-derived satellite cells would act as a key modulator to promote myofiber-type commitment of fast muscles. This work was supported by JSPS KAKENHI and the grant fund from the Ito Foundation.

Isolation and Characterization of Putative Skeletal Stem Cells from the Effluent of Autologous Bone Graft Preparations.

B. Le, A. Wessel, J. Florez, III, W. Yao, M. Lee, F. A. Fierro; University of California Davis, Sacramento, CA.

The recently identified human skeletal stem cells (hSSCs) are essential for maintaining bone homeostasis and for promoting bone repair. Therefore, they present a tremendous potential for the treatment of many orthopaedic applications. However, a major bottleneck is the limited sources for these rare cells. A common method for the harvest of autologous bone graft is the Reamer Irrigator Aspirator (RIA) system, where the intramedullary canal of a long bone (often femur) is reamed, irrigated and aspirated with a filter trap to collect semi-solid stroma/bone material used for grafting procedures. During this procedure, a large volume of liquid and small particles is discarded as waste. Here we show that this waste fluid (RIA effluent), is rich in CD45-CD51+CD200+ cells, which are putative hSSCs. Using single cell RNA sequencing, we demonstrate that this cell population is quite homogeneous, with differentially expressed genes associating with mitochondrial genes and cell signaling. In immune deficient mice undergoing bone fracture, intramuscular injection of hSSCs leads to a significant improvement in bone repair as shown by microCT and calcein staining. Of note, we show that these cells home preferentially to bone and bone marrow after intravenous injection, suggesting that the cells may be applicable to treat systemic skeletal defects, such as osteoporosis. Altogether, our data shows that RIA effluents are a rich source of potential hSSC, which could lead to the development of new regenerative medicines for orthopedic applications.

Gastric Cell Proliferation and Stem Cells Niche: Effects of Early Weaning.

I. C. Rattes, K. M. da Silva, G. M. A. Zonta, A. V. da Costa, P. Gama; University of Sao Paulo, São Paulo, BRAZIL.

Gastric epithelial cells proliferate at the isthmus-neck region of the gland, and this interface is considered the main stem cell niche. In adult animals, an additional inactive- reserve niche is also found at gland base. Such arrangement of proliferative compartment is achieved at weaning time in rats, but the characterization of markers for stem/progenitor cells is still under discussion and little is known about postnatal development. Considering that breastfeeding is important for development program, our hypothesis was that early weaning (EW) might modify the expression of genes that control stem cell activity, and consequently would alter the growth and maturation of stomach. Our aims were to evaluate the immediate and late effects of EW in cell proliferation, at expression genes related to stem cell niche and identify Troy-cell (quiescent stem cell marker) population and distribution in the gastric gland in rats. Wistar rats were submitted to EW (15d) and gastric samples were collected at 15d, 18d and 60d for RT-qPCR, tissue and cell morphology (IHC-P), and immunofluorescence (Ethics Committee CEUA ICB USP 18/2015; 115/2017). We observed that EW augmented proliferation index and thickness of mucosa at 18d, whereas at 60d, Ki-67 immunolabeling variations were not detected. As for genes involved in stem cell niche, EW increased *Tnfrsf19* (Troy) at 18d, but differences were not found at 60d when compared to control (suckling - S). *Notch1* and *Notch2* expression decreased after EW at 18d whereas, both of them increased at 60d. Additionally, *Bmp2* expression was higher at 18d and *Axin2* at 60d. Our results also indicated that in S, at 18d, Troy+cells were found along gland extension, and in the EW group, they were restricted to the isthmus-neck region. At 60d, Troy+-cells were found at the base in S group, whereas it was more spread after EW. We used multiple labeling to study the co-localization of Troy with other epithelial markers and observed that Troy+-cells did not correlate with Ki-67-proliferative cells, but they double-stained with H^+K^+-ATPase, indicating that parietal cell expressed Troy at both S and EW groups at all ages evaluated. Our results suggested that although Troy+ cells do not co-localize with Ki-67-proliferative cells during development, they are sharing the same area, indicating that Troy+ cells are part of the proliferative niche. Additionally, in S adults, we observed Troy+ cell in the quiescent niche, whereas in EW group, its distribution was not restricted to one site. Furthermore, we observed that after EW the expression of genes involved in signaling and stem cell niche behaved differently over aging, and so, the premature dietary change influenced the proliferative compartment.

Estrogen Supplement Enhances the Endothelial Differentiation in Stromal Cells Derived from Adipose Tissue of Rats with Ovariectomy.

S. Leu, H. Chiang; Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, TAIWAN.

The decrease inquantity and quality of stem cells is found to be associated with age, particularly after menopause. The estrogen level is supposed to have an influence on the performance of stem cell therapy in regenerative medicine. The aim of present study is to determine whether estrogen supplement has benefit in promoting endothelial differentiation of adipose-derived stromal cells (ADSC) and enhancing its angiogenic activity. To examine the effect of estrogen treatment on activating estrogen signaling and promoting endothelial differentiation in ADSC, adipose stromal cells were

isolated form adult male rats and cultured in EGM2 medium to induce endothelial differentiation, followed by Western blotting and immunofluorescent staining. Results showed that both expression levels of estrogen receptor α (ERα) and β (ERβ) were increased after estradiol (E2) treatment. Of interest, ERα was localized in the cytoplasm, while ERβ was observed in both nucleus and cytoplasm. In addition, the activation of membrane-initiated estrogen signaling downstream proteins, PI3K signaling, was increased in ADSC cultured with E2 supplement. Furthermore, the phosphorylation level of MAPK signaling proteins, including p38 and JNK, were also increased with E2 treatment. In vitro matri-gel assay showed that the tube and network formation activity of ADSC was up-regulated by E2 treatment. RT-PCR results demonstrated the mRNA expression level of eNOS and VE-cadherin, two indices of functional endothelial cell, andHGF, a pro-angiogenic growth factor, were increased in ADSC with E2 treatment. Results from Western blottings also indicated that protein expression levels of eNOS and VEGF in ADSC were up-regulated by E2 treatment. Flow cytometric analysis further demonstrated that the level of cells positively stained with endothelial cell markers, including CD34, KDR, and CD31 were increased in ADSC cultured with E2. An imal studies also indicated that the number and angiogenic activity of ADSC with endothelial differentiation were reduced by ovariectomy in adult rats, while the impairment of ADSC was rescued by estrogen supplement. In conclusion, the endothelial differentiation of ADSC was enhanced by E2 treatment in vitro and in vivo. while of activation of PI3K and MAPK-mediated estrogen signaling was observed in E2-treated ADSC.

High Mannose N-glycans Promote Migration of Bone Marrow-derived Multipotent Stromal Cells.

V. Alonso-Garcia, C. Chaboya, L. Bryan, T. J. Congleton, J. Florez, III, Q. Li, V. Tran, G. Liu, W. Yao, C. B. Lebrilla, **F. A. Fierro, 95817**; University of California Davis, Sacramento, CA.

Human bone marrow-derived multipotent stromal cells (MSCs) are currently being tested for hundreds of indications, but often therapeutic efficacy has not been achieved due to an inability of the cells to reach target tissues. Here we show that inducing high mannose N-glycans either chemically using the type I mannosidase inhibitor Kifunensine, or genetically using an shRNA to silence expression of mannosidase I A1 (MAN1A1), strongly improve the migration potential of the cells, as determined using wound/scratch assays and videomicroscopy. This increase in high mannose N-glycans also improves active cell migration toward bone fracture after percutaneous injection, and passive cell migration toward lungs after intravenous injection, in immune deficient mice. Mechanistically, high mannose N-glycans induce a change in cell shape, reducing the area in contact to substrate and increasing cell height, as measured using atomic force microscopy. We also show that a reduced contact area strongly correlates with increased cell motility. To determine if pre-treatment with Kifunensine is feasible for future clinical studies, we used NanoLC/ESIQTOF-mass spectrometry to study the N-glycan profile of MSCs over time and demonstrate that the effect of Kifunensine is transitory. We also describe the effect of this compound on cell proliferation, differentiation, and on the secretion profile of MSCs. Altogether, our results support the notion of pre-conditioning MSCs to induce high mannose N-glycans, which leads to increased motility of the cells.

Elucidating the Cell Mechanics That Underlie Stem Cell Niche Morphogenesis.

B. N. Warder, K. Nelson, J. Sui, L. An llo, S. DiNardo; University of Pennsylvania, Philadelphia, PA.

Many of our tissues are maintained and renewed by stem cells. These cells rely on signaling cues from the niche in which they reside. Growing evidence in several systems suggest that the precise organization of niche cells influences how efficiently they control stem cell behavior. Thus, understanding niche morphology will provide insight into how stem cells are maintained. We use the gonad stem cell niche in *Drosophila* to study the mechanics of niche formation. This model combines genetic tractability with powerful live-imaging techniques pioneered in our lab. Our live-imaging has shown dynamics of niche formation during two phases: 1) **assembly** and 2) **compaction**. During **assembly**, pro-niche cells first migrate towards the gonad anterior, gathering in an elongate mass. During **compaction**, the pro-niche cells reorganize forming a smooth, circular contour linked by adherens junctions to its stem cells. These stem cells divide perpendicular to the niche, in order to place daughter cells outside the influence of self-renewing signals. We hypothesize that a smooth contour is crucial to induce properly oriented divisions. I am interested in unraveling cytoskeletal mechanisms that affect compaction and thus affect stem cell function. We show that F-actin and Myosin II (Myo-II) are enriched at stem cell-niche interfaces during compaction. In addition to the enrichment of F-actin and Myo-II, we have shown that there are tensile forces along stem cell-niche interfaces. I hypothesize that these forces are due to actomyosin contractility along niche-stem cell adherens junctions, which function in compacting the niche. I am currently testing this hypothesis by genetically disrupting cytoskeletal modulators and assaying compaction through live imaging. This work will be among the first to describe the mechanisms of shaping a functional niche, and will bridge an important gap in stem cell biology.

Therefore, there must be the mechanisms of “zeroing” this negative effect in the life cycle of lower agamic eukaryotes. According to one of hypotheses the cyclic polyploidy (alternation of de- and polyploidization in the course of life cycle) may play the role of such a mechanism. We have shown that *Amoeba proteus*, a textbook agamic unicellular eukaryote, and related

amoebae species, employ a special kind of cyclic polyploidy, achieving depolyploidization by chromatin extrusion from the nucleus into the cytoplasm. The phenomenon of “extra-DNA” extrusion from the nucleus during the cell cycle was found in some representatives of multicellular organisms from the macrotaxae which were far from each other, and had no phylogenetic connections; in unicellular eukaryotes it was found in macronuclei of some ciliates. It means that the cell mechanisms of nuclear extrusion are rather ancient and universal. Surprisingly, the similar strategy of cell cycle was shown for cancer mammalian cells after genotoxic treatment, in this case it may result in their survival, and, even in increasing of tumor aggressiveness. Thus, our data on amoebae sustain the so-called “atavistic theory of carcinogenesis”. Moreover, the detailed study of those lower eukaryotes whose cell cycles include the strategy of cyclic polyploidization (*Amoeba proteus* among them) may serve the new tool for understanding the roots and mechanisms of high cancer cells stability to genotoxic treatment. This work was partly financed by the Budgetary Program # 0124-2019-0005 at the Institute of Cytology RAS.

The Dark LECA Rises: an cient Proteins with Unknown Functions.

J. G. Wideman[1], T. Richards[2], B. Wickstead[3]; [1]Arizona State University, Tempe, AZ, [2]University of Exeter, Exeter, UNITED KINGDOM, [3]University of Nottingham, Nottingham, UNITED KINGDOM.

Reconstructing the cellular systems of the Last Eukaryote Common an cestor (LECA) is an ongoing challenge. It is commonly accepted that LECA had all of the general features that extant eukaryotes share including a nucleus, mitochondria, flagella, a complex cytoskeletal and membrane trafficking systems, the capacity to engulf prey, and facultative sex. Although these general features of LECA are known, the degree to which LECA is a mystery remains mysterious. An cestral reconstructions are limited by our cell biological knowledge of model organisms and the degree to which functional investigation in models might contribute to human health. This leaves a vast diversity of ancient genes neglected for which no functional information is available. In order to identify ancestral orthologue groups with little or no structural or functional information, we used sequence clustering approaches, tree building, and manual curation to identify two types of ‘dark’ genes in LECA. First, the dark proteome, which comprises genes encoding proteins for which no domain information is available. Second, the dark paralogues, which comprise genes encoding proteins for which domain information is available their precise functions remain unknown. We suggest that between ~10-30% of genes in LECA lack functional or structural annotations leading to the conclusion that our knowledge of the cell biology of the eukaryote ancestor is significantly lacking.

Structural Studies of the Microsporidian Polar Tube.

M. Usmani[1], P. Jaroenlak[1], A. J. Noble[2], C. S. Potter[2], B. Carragher[2], D. C. Ekiert[1], G. Bhabha[1]; [1]Skirball Institute of Biomolecular Medicine and Department of Cell Biology, New York University School of Medicine, New York, NY, [2]National Resource for Automated Molecular Microscopy, Simons electron Microscopy Center, New York Structural Biology Center, New York, NY.

Microsporidia are obligate intracellular, eukaryotic parasites capable of infecting a wide range of hosts from silkworms to immunocompromised humans. They do so through a magnificent organelle known as the polar tube which undergoes tremendous conformational change from being tightly coiled inside the dormant spore to a long, linear tube out of the spore during infection. The filamentous polar tube is

likely composed of repeating units of polar tube proteins (PTPs) whose structures remain a mystery, and which also don't share sequence homology to any known protein. Furthermore, it is not well understood how these proteins are arranged to form the tube. An understanding of the protein structures, as well as how they are arranged to potentially form repeating units and information on the ultrastructure of the tube will be key to understanding the invasion mechanism. We have optimized sample preparation for cryo-tomography and observed two different populations of the polar tube of microsporidia species *Encephalitozoon hellem*. One population contains stripes diagonal to the length of the tube while the other population contains layers which give it a leek like appearance, and these may represent two stages of the polar tube firing process. We are currently trying to perform subtomogram averaging to improve the resolution of our model and optimizing recombinant polar tube proteins for x-ray crystallography. To understand the composition of the tube through proteomics, we have also optimized a method for shearing the polar tube off the germinated spore using sonication which omits the need to use harsh chemicals traditionally used in polar tube extraction. By taking advantage of the advances made in cryo-electron tomography and combining it with crystallography and proteomics we hope to understand how the architecture of the polar tube gives it robust material properties and facilitates infection.

Ensnared Dynamics of Miniature Mitochondrial Organelles.

P. Tůmová[1], **L. Voleman**[2], E. Nohýnková[1], G. Wanner[3], P. Doležal[2]; [1]Institute of Immunology and Microbiology, First Faculty of Medicine and General University Hospital, Charles University, Prague, CZECH REPUBLIC, [2]Faculty of Science, Charles University, Prague, CZECH REPUBLIC, [3]Ultrastructural Research, Biozentrum of Ludwig-Maximilian University, Munich, GERMANY.

Division of the eukaryotic cell is a coordinated process, during which the daughter cells receive, in addition to the nucleus, a set of organelles to maintain all cellular functions. While some organelles like peroxisomes or even Golgi complex can be generated de novo, mitochondria can only bepropagated from the pre-existing organelles. Here, we show that a unicellular eukaryote (protist) *Giardia intestinalis*, earmarked a "germline" set of its mitochondrial organelles known as mitosomes, to ensure their faithful propagation into the daughter cells. These mitosomes divide within secondsonly during the early prophase of mitosis and they are distributed equally with the half set of the cell flagella to daughter cells. Surprisingly, this mitochondrial division occurs even when mitosis is blocked, which results into formation of anucleate cells but with a proper set of mitosomes andflagella. This is achieved by physically connecting "germline" mitosomes to the axonemes of the cell flagella via a specialized lamella made of a sheet of microtubules. The 3D models of the whole mitotic cells generated by FIB/SEM microscopy demonstrate that it is always only the oldest pair of eightflagella to which the mitosomes are ensnared. We propose that the flagellar system controls the segregation of mitochondrial organelles also in other members of this supergroup of eukaryotes. Moreover, the integration of mitochondrion into the flagellar system could have been the originalstrategy of the early eukaryotic cell to maintain its key organelle.

Characterization and Evolution of the Polar Tube of Microsporidia - the Invasion Apparatus of the Intracellular Parasites.

M. Petru[1], A. Satrapova[1], V. Novotna[1], V. Dohnalek[1], W. Zheng[2], E. H. Egelman[2], **P. Dolezal**[1]; [1]Charles University, Prague, CZECH REPUBLIC, [2]University of Virginia, Charlottesville, VA.

Microsporidia are obligate intracellular pathogens, which infect wide spectrum of hosts ranging from protists to vertebrates including humans. Key to the infection is the penetration of the parasite into the host cell [1]. Microsporidia carry unique invasion apparatus built around a hollow proteinaceus tube (polar tube), which is ejected from the infectious spore and allows the parasite to be injected into the host [2]. Polar tube can be as long as 500 micrometers and is built of at least three different proteins (PTP1-3). We have been studying the localization and the interaction of PTPs within the tube in order to understand its biogenesis and structure on a model of silkworm pathogen *Nosema bombycis*. Using super resolution and cryo electron microscopy we have showed that the polar tube is a protein polymer of 100nm in diameter with a periodic pattern of 63 angstroms. Interestingly, this pattern seems to be conserved across different species of Microsporidia despite the great difference in the primary structure of all PTPs [3]. Using the bioinformatic analyses we have mapped the evolution of the polar tube and PTPs across Microsporidia and defined a core set of PTPs, which is common to all species. 1. Weiss, L. P807/B827

Microsporidia Harpoon-like Polar Tube, from Firing Dynamics to Host Cell Entry.

P. Jaroenlak[1], M. C. Cammer[2], J. J. Becnel[3], D. C. Ekiert[1], G. Bhabha[1]; [1]Skirball Institute of Biomolecular Medicine and Department of Cell Biology, New York University School of Medicine, New York, NY, [2]Microscopy core, New York University School of Medicine, New York, NY, [3]Center for Medical, Agricultural, and Veterinary Entomology, Agricultural Research Service, US Department of Agriculture, Gainesville, FL.

Microsporidia are obligate intracellular parasites that infect a variety of invertebrate and vertebrate hosts including humans. Microsporidia employ a unique invasion organelle, the polar tube, that forms a coil resembling a spring inside dormant spores. Under suitable environments, microsporidia fire the polar tube, which extends from its coiled structure to a linear tube, to puncture the host cell membrane and serves as a tunnel for the transferring of the parasite's infectious material. This firing process occurs extremely fast, on the millisecond timescale. Invasion of host cells using the polar tube is thought to be the dominant mechanism of host cell entry. In addition, phagocytosis of whole spores has also been reported to be an alternative route of entry in some microsporidian species. However, little is known about the mechanism of entry, either via the polar tube or via phagocytosis. Here, we optimized high-speed, live-cell optical imaging to capture the firing events from two microsporidian species, an *ncaliia algerae*, which can infect mosquito's gut and human muscles, and *Encephalitozoon hellem*, which mainly infects eye tissue. We find differences in the firing kinetics between the two species, which may be linked to their tissue specificity. To investigate how our in *vitro* studies may be applicable in the

presence of host cells, we developed a fluorescence microscopy-based assay that allowed us to investigate PT-mediated and phagocytosis-mediated entry in host cells. While PT-mediated entry is dominant in *A. Algerae*, phagocytosis-mediated entry is dominant in *E. hellem*. Host cell actin cups form around intact spores during phagocytosis, and also around the naked sporoplasm that enters the host cell via PT-mediated infection. We will discuss the dynamics of the large PT organelle in *vitro*, as well as the microsporidia invasion and entry process in the presence of host cells.

***Invitro* Activity and Mode of Action of Phenolic Compounds on *Leishmania Donovani*.**

C. Moore; Biochemistry, West African Center for Cell Biology of Infectious Pathogens, University of Ghana, Legon, accra, GHANA.

Background: Leishmaniasis is a disease caused by the protozoan parasite, *Leishmania. The* disease remains a global threat to public health requiring effective chemotherapy for control and treatment. In this study the effect of some selected phenolic compounds on *Leishmania donovani* was investigated. The compounds were screened for their anti-leishmanial activities against promastigote and intracellular amastigote forms of *Leishmania donovani.* **Methodology/Principal findings**: the dose dependent effect and cytotoxicity of the compounds were determined using a tetrazolium-based assay. Flow cytometry was used to determine the effect of the compounds on the cell cycle. Parasite morphological analysis was done by microscopy and growth kinetic studies were conducted by culturing cells and counting at 24 hours intervals over 120 hours. The iron chelating property of the selected compounds was determined by atomic absorption spectroscopy and the effect of compounds on the expression of iron dependent enzymes was investigated using RT-qPCR. The IC_{50} of the compounds ranged from 16.34 µM to 124 µM compared to amphotericin B and deferoxamine controls. Rosmarinic acid and apigenin were the most effective against the promastigote and the intracellular amastigote forms. Selectivity indexes (SI) of rosmarinic acid and apigenin were 15.03 and 10.45 respectively for promastigotes while SI of 12.78 and 5.20 respectively were obtained for intracellular amastigotes. Morphologically, 70% of rosmarinic acid treated promastigotes showed rounded morphology similar to the deferoxamine control. About 30% of cells treated with apigenin showed distorted cell membrane. Rosmarinic acid and apigenin induced cell arrest in the G_0/G_1 phase in promastigotes. Elevated intracellular iron levels were observed in promastigotes when cells were treated with rosmarinic acid and this correlated with the level of expression of iron dependent genes. **Conclusions: the** present study showed an effective anti-leishmanial activity of rosmarinic acid and apigenin against *L. donovani* promastigotes and intracellular amastigotes and resulted in changes in the mitochondria integrity and morphology of the cells. Rosmarinic acid and apigenin induced cell cycle arrest in the G0/G1 phase. The findings suggest that rosmarinic acid could be exerting its inhibitory effect against the parasite via iron chelation which results changes in the morphology and the arrest of the cell cycle while apigenin may exert its inhibitory effects by other mechanisms.

P809/B829

Mitochondrial Pyruvate Carrier Subunits Are Required for Pyruvate-driven Respiration, Infectivity, and Intracellular Replication of *Trypanosoma Cruzi*.

R. S. Negreiros[1], N. Lander[2], M. A. Chiurillo[2], A. E. Vercesi[1], R. Docampo[2]; [1]Department of Clinical Pathology, State University of Campinas (Unicamp), Campinas, São Paulo, BRAZIL, [2]Center for Tropical and Emerging Global Diseases, University of Georgia (UGA), Athens, GA.

Pyruvate is the final metabolite of glycolysis. Inside the mitochondria pyruvate can be converted into acetyl-CoA, which is used as substrate for the tricarboxylic acid cycle. Pyruvate metabolism is important to balance glycolysis and oxidative phosphorylation. Pyruvate availability in mitochondria depends on its active transport by a hetero-dimer MPC1/MPC2 which is called the mitochondrial pyruvate carrier (MPC). In this work, we aimed to characterize the *Trypanosoma cruzi* MPC (TcMPC) performing gene knockout and endogenous C-terminal tagging using CRISPR/Cas9 system, and overexpression of *MPC1* and *MPC2* genes. Endogenous C-terminal tagging of *TcMPC1* and *TcMPC2* genes with 3xc-Myc showed that both proteins co-localize with MitoTracker to the mitochondria of epimastigote forms. Individual knockout of *TcMPC1* and *TcMPC2* genes was confirmed by PCR and Southern blot analyses. *TcMPC1*-KO or *TcMPC2*-KO epimastigotes did not show slower growth rate in either regular or low glucose culture medium as compared to the control cell line transfected with scrambled sgRNA. Digitonin-permeabilized *TcMPC1*-KO or *TcMPC2*-KO epimastigotes showed impaired oxygen consumption rates when pyruvate, but not succinate, was used as mitochondrial substrate as compared to the control cell line. Overexpression of *TcMPC1* or *TcMPC2* did not affect oxygen consumption rates. The results suggest that, in contrast to human MPC subunits (Nagampalli et al., 2018), they do not form homo-dimers in the absence of each other. The MPC inhibitor UK5099 (50 µM) was able to completely inhibit oxygen consumption of control cell lines using pyruvate, but not succinate, as substrate. Furthermore inhibition of succinate dehydrogenase by malonate in digitonin-permeabilized control cells impaired pyruvate-driven respiration. Ability of trypomastigotes to infect tissue-cultured cells was reduced three times and replication of intracellular amastigotes was also decreased for both *TcMPC1*-KO and *TcMPC2*-KO cell lines. In conclusion, *T. cruzi* MPC1 and MPC2 are essential for cellular respiration in the presence of pyruvate, invasion of host cells, and replication of amastigote forms. Casein Kinase Regulates Mitochondrial Nucleoid Scission in the African Trypanosome, *Trypanosoma Brucei*.

J. Wiedeman, K. Mensa-Wilmot; University of Georgia - Franklin College, Athens, GA.

The mitochondrial nucleoid (kinetoplast) of the eukaryotic microbe *Trypanosoma brucei* is essential for transmission of human African trypanosomiasis from tsetse flies to humans. Little is known about mechanisms controlling division of the kinetoplast, which contains thousands of catenated circular DNA molecules (kDNA). Using RNAi and a chemical probe, we demonstrate that inhibition of casein kinase 1.2 (TbCK1.2) arrests scission of replicated kDNA, although the enzyme is not detected at the mitochondrion. We hypothesized that TbCK1.2 regulates kinetoplast division through effector proteins. We used a multi-pronged approach (quantitative phospho-proteomics, quantitative proximity biotinylation, and in *vitro* peptide kinase assays) to identify substrates that could be effectors for TbCK1.2. TbLRRP1 was de-phosphorylated after TbCK1.2 knockdown in *vivo*, and its peptide was

phosphorylated by TbCK1.2 in *vitro*. Knockdown of TbLRRP1 inhibited division of kinetoplasts, suggesting a role for the protein as an effector of TbCK1.2 signaling in *vivo.* Successful identification of an effector for TbCK1.2 suggests that our workflow may be used in other eukaryotes to study investigator-chosen biological pathways that are regulated by protein kinases.

Mcu Complex Physically Interacts with Mitochondrial Atp Synthasome in Trypanosomes and Mammals.

G. Huang, R. Docampo; University of Georgia, Athens, GA.

Mitochondrial Ca^{2+} transport mediated by MCU complex plays a key role in the regulation of cell bioenergetics and life-death decisions both in trypanosomes and mammals, but the molecular mechanism has remained unclear. Here we have discovered that *Trypanosoma brucei* MCU (TbMCU), together with TbMCUb and TbMCUc, associates with the mitochondrial ATP synthase, phosphate carrier (PiC) and adenine nucleotide translocator (ANT) forming part of a potential "ATP synthasome", as detected by mass spectrometry of tandem affinity-purified TbMCU complex. Split-ubiquitin membrane-based yeast two-hybrid (MYTH) assays identified that TbMCU physically interacts with *T. brucei* ATP synthase subunit c (TbATPc). Interestingly, the direct physical MCU-ATPc interaction is conserved in trypanosomes and human cells. Combining mutagenesis analysis with MYTH assays revealed that transmembrane helices (TMHs) were determinant of the specific interactions between MCU and ATPc. In *situ* tagging, immunoprecipitation and immunofluorescence microscopy revealed that TbATPc co-immunoprecipitates with TbMCU complex (TbMCUC), and colocalizes with the TbMCUC to the mitochondria of *T. brucei.* Blue Native PAGE and immunodetection analyses indicated that the TbMCUC interacts with the ATP synthase in a large protein complex with a molecular weight of approximately 900 kDa. Ablation of the *TbMCUC* subunits by RNAi significantly increases the AMP/ATP ratio, revealing the down-regulation of ATP production in the cells. Finally, specific interaction between human MCU (HsMCU) and HsATPc was confirmed in *vitro* by mutagenesis and MYTH assays, and in *vivo* by co-immunoprecipitations. In summary, our study has identified that MCU complex physically interacts with mitochondrial ATP synthase, possibly forming an MCUC-ATP synthasome "megacomplex" that couples ADP and Pi transport with ATP synthesis, a process that is stimulated by Ca^{2+} in trypanosomes and human cells.

P812/B832

Studies Resolving Unexpected Functions and Regulation of Fructose 1,6-bisphosphatase in the Parasite *Trypanosoma Brucei*.

C. Wilkinson, L. Crowe, M. Morris; Clemson University, Clemson, SC.

Glucose-6-phosphate (G6P) is a key metabolite, required for both glycolysis and the pentose phosphate pathways. This critical compound is generated by either glycolysis or gluconeogenesis (GNG), with the former utilizing glucose while the later generates G6P from non-carbohydrate sources when glucose is scarce. In most organisms these pathways are localized together within the cytoplasm and reciprocally coordinated via allosteric regulation of key enzymes in the glycolytic and GNG pathways; phosphofructokinase (PFK) and fructose 1,6-bisphosphatase (FBPase). The protozoan parasites *Trypanosoma brucei* are unique in that most of the glycolytic and GNG pathways are localized within a specialized membrane-bound organelle called the glycosome. Additionally, in these parasites PFK and

FBPase activities are not regulated by conditions and molecules known to regulate FBPase and PFK in other systems. The coordination of the pathways is important. *T. brucei* alternates between a source of high (~5 mM) glucose in the mammalian bloodstream as the bloodstream form (BF) and the tsetse fly vector as the procyclic form (PF) where glucose is scarce. We are working to understand how glycolysis and GNG contribute to this metabolic flexibility. While FBPase protein is expressed in all stages of the lifecycle, activity has been challenging to monitor. To overcome this hurdle, we developed a sensitive in *vitro* assay and used it along with western blot analysis to follow FBPase protein and activity levels. Using these tools, we have found that FBPase protein levels were 2-fold lower in BF parasites as compared to PF, while FBPase activity was 2-fold higher. We hypothesize that the increase in activity is the result of post-translational modification(s) to the protein. In PF parasites FBPase protein and activity levels were both increased when parasites were cultured in high-glucose conditions. This observation that FBPase activity is greatest in high-glucose conditions, when glycolysis (not GNG) is expected to be the active metabolic pathway suggests that the protein may serve a function that is distinct from GNG. As we identify proteins and pathways that are affected by changes in FBPase levels, we anticipate identification of unexpected roles for FBPase in the protozoan parasite.

Modulation of Glucosylceramide Synthase Expression Alters the Growth and Differentiation of an an cient Protist, *Giardia Lamblia*.

V. Enriquez, B. Grajeda, C. Ellis, S. Das; University of Texas at El Paso, El Paso, TX.

The waterborne parasite, *Giardia lamblia*, is a major cause of the zoonotic diarrheal illness (giardiasis) worldwide. *Giardia* is classified as a “model organism” to study evolution because of its compact genome and reduced metabolic pathways. It lacks emblematic eukaryotic organelles such as mitochondria and Golgi complexes. The infection by *Giardia* is transmitted by the cyst form in contaminated food, water, or feces. *Giardia* maintains a simple life cycle, i.e., trophozoites and cysts. Ingested cysts undergo excystation in the proximal small intestine, releasing trophozoites that initiate infection in the gut. Upon reaching the distal small intestine, trophozoites transform into cysts (encystation) and are excreted in stool, thus completing the life cycle. It has been shown that giardial glucosylceramide synthase/transferase (gGlcT1), an enzyme of the sphingolipid metabolic pathway, is critical for inducing encystation, cell division, and vesicular trafficking. In addition, our laboratory has reported that gGlcT1 is a dual-substrate enzyme, with separate catalytic domains that facilitate the synthesis of glucosylceramide and galactosylceramide. The goal of this project is to characterize gGlcT1 and evaluate whether the modulation of its synthesis can influence the structure of cysts since oval-shaped cysts are infective and undergo excystation. Three expression constructs were developed to express gGlcT1: (1) gGlcT1 under its own promoter with an endogenous C-terminal HA tag (endo-gGlcT1-HA); (2) an overexpression plasmid containing an α_2-tubulin promoter (α_2-Tub-gGlcT1-AU1) and (3) a plasmid under a strong giardial OCT (ornithine carbamoyltransferase) promoter (OCT-gGlcT1-HA). Under the different promoters, it was found that the enzyme expression and activity were modulated, and cyst production was reduced. Proteomic analysis showed that gGlcT1 overexpression altered the expression of glycolytic and pentose-phosphate pathways that are involved in producing energy under anaerobic conditions. Furthermore, truncation mutations of gGlcT1 provided insight into the catalytic regions important for triggering encystation and its cellular and metabolic functions. These results suggest that the regulated expression of gGlcT1 is critical for the growth and differentiation of *Giardia*, therefore it could serve as an ideal target for developing anti-giardial therapies.

P814/B834

Identification of Metazoan Transcription Factor, Which Interacts with the Minimalist Mitochondria-related Organelles of Parasitic Protist *Giardia Intestinalis.*

M. Vinopalová, L. Marková, J. Pelc, V. Najdrová, Z. Füssy, L. Voleman, P. Doležal; Charles University, Faculty of Science, Department of Parasitology, Prague, CZECH REPUBLIC.

Giardia intestinalis is a parasitic protist inhabiting human and animal gut. The parasite is spread via an infectious cyst, which is formed during the passage through the digestive tract of the host. *Giardia* has a very unique cellular structure. It has two nuclei, eight flagella and large adhesive disc by which it attaches to the gut epithelium. Instead of aerobic mitochondria, *Giardia* carries minimalist double-membrane organelles called mitosomes. We have identified *Giardia* homologue of Mlf1IP (Myelodysplasia-myeloid leukemia factor 1-interacting protein) in a novel cellular compartment in close proximity to the mitosomes. The protein was originally described as Metazoa-specific. However, using the large scale bioinformatic analysis, we have shown that Mlf1IP can be found in all major groups of eukaryotes. In animal cells, Mlf1IP has been characterized as a nuclear transcription factor, for which cytosolic localization has also been documented. There the protein acts as a negative regulator of cell cycle progression. We have been investigating GiMlf1IP in order to understand the functional connection between the Mlf1IP-containing compartment (Lin et al. 2019) and the mitosomes. Interestingly, various truncated forms of Mlf1IP retained its localization close to mitosomes. Using the affinity purification method, we identified mitosomal outer membrane proteins among its putative interaction partners. Surprisingly, the overexpression of Mlf1IP interferes with the encystation of the parasite, indicating its possible role in cell cycle regulation even in this single-cell eukaryote.

Molecular Characterization of *Giardia Lamblia* in Bivalves Collected in New York.

G. Mayer, A. Marcazzo, F. Diallo; Manhattan Coll, Riverdale, NY.

Giardia lamblia, a flagellated protozoan parasite, if ingested, infects the lumen of the small intestines in humans. This parasite is found in various animals, such as dogs, cats, and birds. *G. lamblia* is most commonly transmitted to humans via ingestion of contaminated food and water. Its presence in marine environment is relatively unorthodox and its presence in public waterways is a public health concern. The goal of this study is to determine the prevalence of *G. lamblia* in Atlantic oysters *(Crassostrea virginica*) and ribbed mussels (*Geukensia demissa*) collected from Orchard Beach and Clason Point, Bronx, NY. Each year, the mussels were collected in the fall. Tissues were dissected, followed by DNA extraction and PCR analysis. Thus far, we found a marked fluctuation in the prevalence of *G. lamblia* in both bivalves from 2014-2018, ranging from no 4.5% to 42%, with no parasite detected in 2015 in the ribbed mussels collected from Orchard beach. In addition, a change in the genotype of *G. lamblia* was observed from year to year, with assemblage a being more frequent. In 2017, assemblage a was most prevalent at Orchard beach (73.68%) and sub-assemblage AI was most prevalent and Clason Point (73.46%), indicating different genotypes of *G. lamblia* at those two locations. In conclusion, Atlantic oysters and ribbed mussels may be used as a biological sentinels to detect *G. lamblia in* public waterways and reservoirs.

P816/B836

Molecular Characterization of *Giardia Lamblia* in Oysters (*Crassostrea Virginica*) Collected at Two Beach Sites in New York City in 2018.

F. Diallo, G. Mayer; Manhattan Coll, Riverdale, NY.

Giardia lamblia is a known zoonotic endoparasite that proliferates in the small intestines of vertebrates. In humans, it is responsible for giardiasis, which is an infection of the small intestines, leading to diarrhea. *G. lamblia* has also been associated with the development of irritable bowel syndrome and chronic fatigue in humans. Previous research in our laboratory and others have found a high prevalence of *G. lamblia* in tissues of bivalves living in marine environment. The objective of this research is to determine the genotype and prevalence of *Giardia lamblia* from two beach sites, less than 10 miles apart, located in the Bronx borough of New York City using molecular techniques. A total of 39 oyster specimens were collected in the fall of 2018 during low tide, 16 at Orchard Beach and 23 at Clason Point. Each specimen was dissected to isolate the digestive gland, adductor muscle, mantle, gills, and hemolymph. DNA was extracted from each tissue. To detect *G. lamblia,* nested-PCR was performed using primers that target the β-giardin gene. The prevalence of *G. lamblia* DNA was found to be 8.7% at Clason Point, while it was 12.5% at Orchard Beach, respectively. The mantle was the tissue displaying the highest prevalence of *G. lamblia* DNA. The genotype of *G. lamblia* at both locations was found to be assemblage A. In summary, variation in the prevalence of *G. lamblia* was observed between the two sites, but not in the genotype. It is important to investigate the prevalence of *G. lamblia in* oysters which are often consumed raw. In addition, oceans are commonly frequented by a large number of individuals during the hot summer months.

P817/B837

Characterization of *Giardia Lamblia in* Blue Mussels Collected from Two Beach Sites in New York City.

J. Lopez, **G. Mayer**; Manhattan Coll, Riverdale, NY.

Giardia lamblia is an intestinal parasite commonly found in rivers. It is the causative agent of giardiasis in humans. Bivalves have been shown to carry the intestinal parasite *G. lamblia. The* goal of this research is to determine the prevalence of *G. lamblia in* blue mussels (*Geukensia demissa*) species from both Orchard Beach and Clason Point in New York. Specimens were collected in the fall of 2018 and each specimen was dissected to harvest the mantle, gills, foot, digestive gland, abductor muscle, and hemolymph. A total of 20 specimens were tested from Clason Point and a total of 42 specimens were tested from Orchard Beach. The prevalence of *G. lamblia* for specimens collected from Clason Point was 55% and 4.80% for those collected from Orchard Beach. The *G. lamblia* parasite was found in all of the tissues except for the foot and hemolyph. Further, the mantle tissue had the highest prevalence of *G. lamblia* for Clason Point, while the gill tissue had the highest prevalence for Orchard Beach.

From Ciliate Biology to Physical Models of Mechanically Encoded Cell Behavior.

S. Coyle[1,2], E. Flaum[1], D. Krishnamurthy[1], M. Prakash[1]; [1]Stanford University, Stanford, CA, [2]University of Wisconsin — Madison, Madison, WI.

Ciliates are extraordinary single celled eukaryotes that use rapid morphology changes to perform fast animal-like behaviors such as jumping, grabbing and hunting. These behaviors are built from a toolbox of molecular components—motile cilia, cytoskeletal structures, and contractile machinery—that are

regulated in space through different cell geometries and in time through signaling controllers that rapidly regulate activity. To understand how these activities can be used to build microscale molecular machines with complex behaviors, we analyzed the hunting dynamics of the predatory ciliate *Lacrymaria olor*, which locates and captures prey using the tip of a slender "neck" that can rapidly extend more than ten times its body length (500 µm from its body) and retract in seconds. Although its hunting behavior appears complex, a detailed quantitative analysis of the cell's shape dynamics shows that it actually locates prey through rapid, near-random, dense sampling of the area within the neck's radius. To execute random search in a challenging low-Reynolds number environment, the cell exploits elasto-hydrodynamic buckling responses of its cytoskeleton to repeated cycles of extension and retraction using its ciliary and contractile machinery. Inspired by these observations, we develop a high fidelity elasto-hydrodynamic physical model in which arbitrary cytoskeletal geometries can be coupled to a surface activity to generate emergent dynamics. Using this model we first explore the cell's hunting behavior by elucidating the design principles and control signals to the underlying molecular components that underlie this behavior. More broadly, we explore how such a model can be used to explain the diversity of forms and functions within the *ciliaphora*.

P819/B839

The Fine Structure of the Tentacular Apparatus of Adult Ctenophore*Mnemiopsis Leidyi*.

G. Dong, A. Moss; Auburn University, Auburn, AL.

The common Western Atlantic ctenophore *Mnemiopsis leidyi* is currently the object of intense ecological and physiological study because several multigenetic molecular analyses have shown Phylum Ctenophora to be the sister taxon to all other animals (Science 342:1242592; Nature 510:109). The tentacular apparatus of ctenophores is critical to feeding and very likely bears a diversity of sensory functions. Previous studies of the cydippid *Pleurobrachia pileus* suggest that the tentacular bulb is an integrative center for afferent signals arising from the distal tentacle (Trans Roy Soc. B 339:1) as well as a cell proliferation zone (Dev Biol 350:183). The tentacular apparatus of adult cydippid and lobate ctenophores have previously been presumed to be superficially similar but as we show here, display distinct cellular organization. Here, we show a new view of tentacular apparatus structure and compare to the original work of Mayer in 1912. Oblique illumination light microscopy reveals a fan-like ridge of tissue located on the center of the bulb previously misinterpreted to be the 'principle tentacle' (Hyman, 1940). The fan comprises hundreds of tentillae that continually arise from the center edge of the ridge, thus each tentillum connects directly to the bulb. These findings are contrary to previous conclusions that the tentillae are side branches of a larger cydippid-like tentacle embedded in the epithelia of the food groove. We created a lesion in the tentacular groove to attempt to establish continuity of the tentillae within the food groove. We used time-lapse recording to reveal the post-incision recovery mechanisms of the tentacular groove and the tentillae. Tentillae do not arise locally from the tentacular groove but instead form at the bulb and extend the full length of the feeding apparatus. Thin section analysis of the tentacular bulb reveals distinct regions in the bulb. Major features include: 1) that the bulb emerges from the epithelium at its oralmost end; 2) a pair of canals that underlie the bulb along its full length; 3) a distinct region of bulb myo-neuroepithelium is located on the mid-line in the fan; 4) a region of tentillar longitudinal fission and growth (TLFG) that moves laterally to either side of the bulb to 'feed' tentillae within the feeding groove; 5) a region of apparent cellular proliferation specifically underlying the TLFG; 6) cells with highly condensed chromatin aggregates, that we interpret to be indicative of an unusual form of cellular suicide.

P820/B840

A *Plasmodium* Homolog of Er Tubule-forming Proteins Is Required for Parasite Virulence.

X. Shi[1], L. Hai[1], K. Govindasamy[2], J. Gao[1], I. Coppens[3], J. Hu[4], Q. Wang[1], **P. BHANOT**[2]; [1]Tianjin Medical University, Tianjin, CHINA, [2]Rutgers New Jersey Medical School, Newark, NJ, [3]The Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, [4]Institute of Biophysics, Chinese Academy of Sciences, Beijing, CHINA.

Reticulon and REEP family of proteins stabilize the high curvature of endoplasmic reticulum (ER) tubules. *Plasmodium berghei* Yop1 (*Pb*Yop1) is a REEP5 homolog in the *Plasmodium* genome. Here we characterize its function using a gene-knockout (*Pb*yop1Δ). *Pb*yop1Δ parasites display loss of ER architecture, an enlarged digestive vacuole and severe attenuation of the asexual cycle. Sporozoites have reduced speed and are slower to invade cultured hepatocytes. We propose that *Pb*YOP1's disruption leads to defects in trafficking and secretion of a subset of proteins required for parasite development and invasion of host cells. Consistent with this defect, *Pb*yop1Δ-infected mice display lower incidence of experimental cerebral malaria (ECM) and reduced brain expression of CD8+ T-cell effectors. ICAM-1 protein expression is specifically reduced in the brainstem, indicating decreased activation of endothelial cells, which are known to cross-present parasite antigens to CD8+ T-cells. We propose that *Pb*YOP1-dependent processes are required for parasite-mediated activation of CD8+ T-cells in the brain during ECM.

Elucidating the Origin of an imal Cell Types through the Mechanisms of Cell Type Regulation in the Choanoflagellate *Salpingoeca Rosetta*.

M. Coyle, N. King; University of California, Berkeley, Berkeley, CA.

In every animal, distinct cell types perform specialized roles, yet we have little insight into the evolutionary trajectory that led from unicellular life to this incredible collaboration of specialized cells. While animals specify cell types using interconnected, hierarchical, and modular transcriptional networks, it is poorly understood how the nature and evolution of these networks influenced the origin of animal cell types. One barrier to this understanding is the limited phylogenetic diversity of taxa in which the transcriptional regulation of cell types has been studied. I am unraveling the transcriptional control of a cell type transition in the choanoflagellate Salpingoeca rosetta, one of the closest living relatives of animals. I am also assessing the transcriptional modularity of sub-cellular functions in *S. rosetta*, the patterning of cis-regulatory information across its condensed genome, and the role of histone post-translational modifications with regards to cell type regulation and transcriptional control. This study will broaden our understanding of cell type regulation across the phylogenetic tree, particularly with detailed information about the closest living relatives of animals. Additionally, this knowledge may help to infer attributes of pre-animal transcriptional networks and guide our understanding of the origin of animal cellular differentiation.

Leukocyte Transendothelial Migration Mimicry:a Novel Mechanism In*Trypanosoma Cruzi*-host Interaction.

S. Panagiotidou, M. Perrin; Tufts University School of Medicine, Boston, MA.

The Chagas disease parasite *Trypanosoma cruzi* primarily infects the heart and gastrointestinal tract and the infection may trigger structural and functional aberrations such as cardiomegaly, megaesophagus, and megacolon. To reach the organ parenchyma, where it thrives and multiplies inside a variety of cell types, *T. cruzi* must cross the vascular endothelium. If it does not, the protozoan pathogen will likely perish in the bloodstream**.** However, the mechanisms underlying *T. cruzi*transendothelial migration (TEM) remain to be determined. We hypothesize that *T. cruzi* takes advantage of the molecular machinery leukocytes use for TEM, a pathway essential for immune cells to access tissues to combat injury and microbial invaders. Much is known about the molecular interactions required for multistep leukocyte TEM. The first step consists of leukocytes decelerating by binding to the adhesion molecules P-selectin (SELP) and E- selectin (SELE) located on the endothelial luminal surface. The binding requires P- and E- selectins reaction with sialyl and sulfate residues on the ligand P-Selectin Glycoprotein Ligand 1 (PSGL-1) expressed by leukocytes. Our results show that endothelial cells exposed to *T. cruzi* strongly upregulate both SELP and SELE genes, suggesting that *T. cruzi* controls expression of at least part of the molecules responsible for TEM. Both SELP and SELE bind to *T. cruzi* in a dose-dependent and saturable manner, and the binding requires sialyl and sulfate residues, akin to leukocyte-PSGL-1 recognition. Furthermore, preincubation of *T. cruzi*with SELP or SELE prevents *T. cruzi* entry into endothelial cells, implying that *T. cruzi* interaction with selectins guide migration of the parasite through the endothelium. Thus, our findings suggest that *T. cruzi* mimics leukocytes in traversing the endothelial barrier in its way to reach parenchymal host cells. Aside from unveiling a novel mechanism in *T. cruzi*-host interaction, understanding *T. cruzi* TEM may also suggest a novel therapeutic avenue for incurable Chagas disease.

P823/B843

Demonstration of Rna Interference by Feeding In*Stentor Polymorphus*, a Potential Model for the Study of Host-symbiont Interactions.

M. M. Slabodnick; University of North Carolina, Chapel Hill, Chapel Hill, NC.

Stentor is a genus of large trumpet-shaped unicellular organisms in the ciliate phylum. Classically they have been used as models for morphogenesis due to their large size and ability to regenerate, but some *Stentor* species have features that make them useful models for other types of studies as well. *Stentor polymorphus* is a widely distributed species that harbors green algal endosymbionts from the *Chlorella* genus. While interesting phenomenology in this species has been described, molecular tools have never been developed in this system. As technology has advanced, the use of emerging models like *S. polymorphus* has become more prevalent, and recently a set of transcriptomes for *S. polymorphus* was published. However, there are still technical hurdles to using this emerging model as an experimental system in the lab. Here I describe the identification and culture of a *S. polymorphus* population from North Carolina as well as the identification and cloning of homologs of α-tubulin and *MOB-1*. Additionally, I demonstrate that RNA interference (RNAi) by feeding is effective against both of these homologs in *S. polymorphus*. These two RNAi targets were previously validated in *S. coeruleus and* the observed phenotypes were similar to the phenotypes observed in *S. polymorphus*. A direct comparison between the two species revealed that RNAi appeared to be less effective in *S. polymorphus*. The ability

to perform RNAi in *S. polymorphus* strengthens its use as an emerging model for fascinating biology like the mechanisms of unicellular regeneration or host-symbiont interactions and suggests that RNAi by feeding might be more broadly effective across the *Stentor* genus.

P824/B844

Single Domain Antibodies Targeting Histones as a New Tool for Detection and Discrimination between *Leishmania (v.) Braziliensis*And *Leishmania (v.) Peruviana*.

A. ARONI-SOTO[1], A. GUILLEN[1], P. KRISTENSEN[2], J. AREVALO[1]; [1]Universidad Peruana Cayetano Heredia, Lima, PERU, [2]Aalborg University, Aalborg, DENMARK.

American cutaneous leishmaniasis (ACL) is a major public health parasitic disease in New World. Most endemic areas lack of an efficient point of care diagnosis test and solely have access to microscope for giemsa-stain smear diagnosis depending in parasites number in a wound. Drug treatment options should be decided by *Leishmania* species essentially when a severe form caused by *Leishmania (V.) braziliensis* is the cause agent. Molecular tools are costly and need requirements restricted for point of care centers. We decided to use single domain antibodies for their characteristic of small-sized, heat stability, high solubility, antigen specificity and reproducible production. In the present study, our aim is to determinate single domain antibodies for Leishmania detection and identification. We incubated the single domain antibody phage library, PREDATOR, against native histones of *L. (V.) braziliensis* promastigotes by a stringent process with positive and negative selections based on Phage Display technology. The single domain antibody S4B1 was able to detect *L. (V.) braziliensis* and *L. (V.) peruviana* unlike others species. Using blot assays we are able to discriminated these two closest species using a conserved protein like histones. In ELISA assays, S4B1 showed a limit detection less than 630 ng/ml of purified native histones. In addition, when we evaluated antibody S4B1 by immunohistochemistry assays, we were able to detect the nucleus of amastigote, stage present in naturally infected human biopsy. In conclusion, a biopanning process of the PREDATOR library allowed us to select the antibody S4B1, particular for high sensitivity and very specific detection capability. This antibody S4B1 is in developing for conditions for be using in point of care centers.

P825/B845

Tglaforin, a Glucan Phosphatase, Modulates Central Carbon Metabolism in *Toxoplasma Gondii*.

R. D. Murphy[1], A. Dhara[1], E. A. Watts[2], C. O. Brizzee[1], R. C. Sun[1], A. P. Sinai[1], M. S. Gentry[1]; [1]University of Kentucky, Lexington, KY, [2]University of Georgia, Athens, GA.

Toxoplasma gondii is an intracellular, protozoan parasite that currently infects roughly one-third of humans worldwide. The asexual stage *of T. gondii*, found in humans, consists of two morphologically distinct forms: the tachyzoite and the bradyzoite. The rapidly dividing tachyzoites define the acute phase of infection, and convert to slow growing, encysted bradyzoites during the chronic phase. A distinguishing characteristic of bradyzoites, noticeably absent in tachyzoites, is their ability to accumulate starch-like glucose polymers known as amylopectin granules (AGs). Importantly, the *T. gondii* genome encodes the activities needed for AG (starch) utilization. These include a glucan-water dikinase (TgGWD; TGME49_214260), a glucan phosphatase (TgLaforin TGME49_205290), and multiple amylases. These activities comprise a cycle of reversible phosphorylation required for starch degradation. To determine if such a cycle is critical for AG degradation in *T. gondii*, we utilized both biochemical and molecular genetics approaches. We expressed active, recombinant TgLaforin, which

necessitated the use of the Sf9 insect cell expression system. Using several biochemical assays, we confirmed that TgLaforin is an active glucan phosphatase. Biophysical techniques including multi-angle light scattering (MALS) and differential scanning fluorimetry (DSF) have revealed an oligomeric state for TgLaforin, and provided insights into protein organization, stability, and substrate specificities. A CRISPR-Cas9 knockout of TgLaforin in tachyzoites results in a minimal fitness defects in nutrient-replete media. However, potential compensatory changes in the TgLaforin-KO suggest a rewiring of central carbon metabolism, as revealed by metabolomics analyses. Unexpectedly, these findings were confirmed by the KO's dependence on glutamine for growth, even in glucose replete conditions. Moreover, a tachyzoite to bradyzoite conversion assay using alkaline stress revealed that KOs retain tachyzoite markers despite the simultaneous development of bradyzoite characteristics. Even though tachyzoites are not known to utilize AGs, these results suggest that AG metabolism may play a role throughout the asexual stage of these parasites.

P826/B846

***Trichomonas Vaginalis* Infection Causes Pro-neoplastic Changes in Prostate Epithelial Cells & in Orthotopic Rat Model.**

B. Kushwaha, S. Rajender, G. Gupta; CSIR-Central Drug Research Institute, Lucknow, India, Lucknow, INDIA.

Recent studies suggest that Trichomonosis, caused by the human-infective parasite *Trichomonas vaginalis* (Tv), is associated with increased risk of prostate cancer. However, the detailed mechanism of Tv infection associated inflammation and the generation of anomalies (premalignant/ malignant) in prostate is not clear due to the lack of an acceptable experimental model. Hence, host-parasite studies in *vitro* and development of a rodent model could be important in improving our understanding of the prostatic anomalies caused by parasite. We hypothesized that the effect of Tv infection on multiple inflammatory mediators in the prostate could contribute to the development of pathological changes. A co-culture of RWPE-1 cells with Tv modulated multiple pro-inflammatory cytokines/chemokines (IL-1α, IL-1β, IL-2, IL-3, IL-6, IL-7,IL-12, IL-16, PDGF, IFN-γ, TGF-β1, GC-SF, GM-CSF, sTNFR1, sTNFR2, IL-8, MIP-1α, I-309, MCP-2, EOTAXIN, MIG, and RANTES), various other critical inflammatory mediators (STAT-3, NF-κB p65, COX-2, MIF) and enhanced cell survival pathways (including AKT, ERK, p38). In addition, prostate cancer cell line (DU145) underwent a phenotypic shift from epithelial to a mesenchymal-like phenotype when co-cultured with Tv. The acquired phenotype involved the enhancement of cell migration and invasion, with an increased expression of vimentin, FAK and decreased expression of E-cadherin. Furthermore, a Tv infected Sprague Dawley rat model was developed by intra-prostatic injection of Tv and harvesting of prostate glands at different time intervals (10, 30, 50, 70, 90, 110 and 130 days) for experiments. Histology and Immunohistochemistry data established that the parasite infection promoted cell proliferation of the host prostate cells by increased expression of Ki-67 and PCNA. Consistent with our in *vitro* results, we found that Tv infection altered multiple pro-inflammatory signalling proteins and cytokines/chemokines in the host prostatic cells. In conformity with the co-culture experiments, we also observed high expression of PSA (a biomarker of Prostate Cancer) in Tv-infected rat prostate that directly correlated with the severity of Tv infection. Interestingly, Tv induced prostatic anomalies could be reversed in the rat model by administration of metronidazole (USFDA approved 5-nitroimadazole anti-trichomonal drug). Overall, we have developed a Tv-infected prostate model in rat with an aim to delineate the pathogenic mechanisms associated with the parasite infection in humans. This model offers critical insights about the complex interactions between the parasite and

host, which may be useful in the prevention and/or development of intervention strategies against the parasite-induced prostatic neoplasia.

Gain-of-function Mutation in Erythrocyte Mechanoreceptor Piezo1 Causes Dense Cells Resistant to Malaria Parasite Invasion.

Y. Kegawa, H. Waters, L. Bezrukov, S. Glushakova, J. Zimmerberg; Section on Integrative Biophysics, Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD.

PIEZO1 is a non-selective cation channel in mammalian, but not parasite cells, that is activated by mechanical stimulation. In erythrocytes, PIEZO1 functions in tandem with $K_{Ca}3.1$ (Ca^{2+}-dependent K^+ or Gardos channel) to controls cell volume. In mouse models and in humans, gain of function mutations of host mechanoreceptor PIEZO1 (GoF-PIEZO1) led to impaired malaria parasite propagation in erythrocytes. GoF mutations of PIEZO1 are linked to hereditary xerocytosis, a human hematological disorder featuring dehydrated erythrocytes probably due to increased intracellular Ca^{2+} and decreased intracellular K^+. Indeed, dehydration of sickle cells correlates with protection against severe malaria in sickle carriers. Blood of three out of 22 tested African American donors had the most prevalent GoF-PIEZO1 mutation (E756del). Comprehensive analysis of *P. falciparum* replication in erythrocytes from these E756del carriers revealed no major defects. However, some schizonts grown in carriers' blood had distorted or dehydrated morphology, reminiscent of schizonts we previously analyzed in sickle cells from AS carriers. Isolated, dense erythrocytes from E756del carriers showed impaired parasite replication. Interestingly, isolated dense erythrocytes from non-GoF subjects showed impaired replication as well. The parasite erythrocyte cycle in dense cells had normal duration, kinetics of egress, and numbers of de-novo produced parasites per schizont, but impaired parasite invasion. Chemical activation of the PIEZO1 channel in normal erythrocytes by PIEZO1 agonist Yoda1 caused their dose-dependent dehydration, persisting at least three hours after its washout. Morphological abnormalities persisted even longer. Replication of parasites in Yoda-treated erythrocytes was slightly diminished in whole blood and severely diminished in Yoda-treated dense erythrocytes. In summary, dense erythrocytes, whether from GoF-PIEZO1 E756del carriers or not, are defective in supporting *P. falciparum* replication in *vitro*. Dehydration to the point of densification may be a final common pathway to understanding the mechanism of invasion in malaria parasite biology.

Controlling the Developmental Switch between a Human-like to a Yeast-like Cell in a Chytrid Fungus.

K. A. Robinson, S. M. Prostak, L. K. Fritz-Laylin; University of Massachusetts Amherst, Amherst, MA.

Actin is a core and highly conserved component in every eukaryotic lineage. Despite this conservation, actin networks drive a vast array of behaviors, often within the same cell. Our previous work shows that the pathogenic chytrid fungus *Batrachochytrium dendrobatidis* (Bd) exhibits temporally and phenotypically distinct actin networks. During its juvenile stage, Bd uses a single posterior flagellum to swim through water and actin-filled pseudopods and an actin cortex to crawl across surfaces, resembling amoeboid animal cells. As the chytrid matures, Bd switches to a sessile stage utilizing actin

patches and cables to facilitate the growth of a hyphal-like rhizoid and an exit tube for the internally replicated juveniles, resembling filamentous fungal lineages. We discovered that mucin, a signature of Bd's host environment, acts as an external switch to trigger the transition between the two life stages within minutes. Further, we have employed small molecule inhibitors of actin assembly to impair actin pseudopods and filopodia-like protrusions prior to this transition. With these tools, we can control both Bd's transition and ability to assemble distinct actin networks, to ultimately characterize the role of actin during development. Moreover, we are currently determining the mechanisms of Bd's reaction to mucin by assessing its substrate trigger specificity, its characteristic cell polarity markers, and potential developmental pathways through drug inhibition. In addition to answering questions about actin evolution and network regulation, a better understanding of Bd's cell biology will aid in our efforts to combat chytridiomycosis - skin infections causing a dramatic decline in amphibian populations worldwide.

P829/B849

A New Window into the Evolution of Fungal and an imal Cell Biology: Genetic Transformation of the Chytrid *Spizellomyces*.

E. M. Medina[1], K. A. Robinson[1], L. K. Fritz-Laylin[1], N. E. Buchler[2]; [1]University of Massachusetts, Amherst, MA, [2]North Carolina State University, Raleigh, NC.

Chytrids are deep fungal lineages that display traits associated with both animals and fungi, making them evolutionary transitional lineages. Chytrid spores and gametes, called zoospores, lack a cell wall, move with amoeboid movement and swim with a motile cilium nucleated from a centriole, all characters found in animal cells but lost in other fungi. The zoosporic stage then transitions into a more typical fungal developmental program, by building a cell wall and undergoing synchronous nuclear divisions without cytokinesis before cellularizing and releasing new zoospores. The later stages of this developmental program are reminiscent of the cellularization of the *Drosophila* embryo and *Dictyostellium* polarized epithelial development, suggesting that the toolkit for multicellularity may have predated the divergence of the animal and fungal lineage. This unusual cell biology makes chytrids important research organisms to explore the emergence of multicellularity. Moreover, chytrids can provide an evolutionary framework for integrating animal and yeast cell biology: this single research organism developmentally switches from a ciliated amoeba with an actin cortex and protrusions into a "yeast" that undergoes a multicellular-like developmental program. To capitalize on chytrid biology, we have developed a method for stable and reliable genetic transformation of the soil chytrid *Spizellomyces*. By combining expression of fluorescently tagged proteins and live-cell imaging we have taken the first steps towards developing *Spizellomyces* as a model for animal-fungi evolutionary cell biology. We show how polymerized actin drives zoospore motility, and forms transient perinuclear actin shells that coincide with nuclear division. Additionally, we describe how the formation of membrane cleavage planes during cellularization may depend on the formation of three-dimensional polygonal territories of polymerized actin. We are currently extending these tools to use *Spizellomyces* as a model system to study the evolution of key animal and fungal traits, particularly cell cycle regulation, the evolution of cellular motility and the fungal developmental program.

P830/B850

Quantifying the Spatio:temporal Levels of Reactive Oxygen Species in *Cochliobolus Heterostrophus* during Germination and Interaction with Maize Using the HyPer Sensor.

T. Chaya[1,2], N. M. Donofrio[1], J. L. Caplan[1,2]; [1]University of Delaware, Department of Plant and Soil Sciences, Newark, DE, [2]Delaware Biotechnology Institute, Newark, DE.

The interplay between plant host and fungal pathogens during infection is a complex process that is in part defined by regulation of Reactive Oxygen Species (ROS). It is well established that plants use ROS as a key component of innate immunity, growth and development. An alogously, fungi need ROS for development and production of necessary infection structures. In both organisms, ROS production must be carefully regulated to prevent deleterious effects. Our research is exploring the ROS kinetics in the necrotrophic ascomycete *Cochliobolus heterostrophus* which infects maize. To aid in the understanding of this process we have transformed *C. heterostrophus to* express a genetically encoded fluorescent reporter for hydrogen peroxide (H_2O_2) called HyPer. Using confocal microscopy, we are employing an in vitro and in planta analysis for a complete understanding of the role of ROS within *C. heterostrophus*. The in vitro analysis is quantifying the response of conidia to external stimuli in a gravity perfusion system on a confocal microscope. The perfusion analysis permits us to flow oxidative (H_2O_2) , reducing (dithiothreitol), or plant extracts across the conidia in a controlled manner and visualize the kinetics of the response. The second approach is imaging *C. heterostrophu*s ROS levels during infection of B73, a susceptible maize line. This is a well studied line and commonly used to generate hybrids. Single conidium are image from germination to appressorial development and entrance into the host and the fungal ROS levels are quantified. During infection there is a decrease in ROS seen as the invasive hyphae enters the host, after which it increases back to pre-infection levels. The future quantification of the HyPer sensor during infection of resistant lines will provide insight into the role ROS plays in a necrotrophic pathogenic interaction and provide useful information in breeding more robust maize lines.

P831/B851

Antifungal Mechanism of Curcumin in *Candida Albicans* Mediated by Nitric Oxide.

M. Kwun, **D. Lee**; Kyungpook National University, Daegu, KOREA, REPUBLIC OF.

One of the most pathogenic fungi existing, *Candida albicans* have caused great threats to humans. In an objective to discover antifungal effect regarding *C*. A*lbicans*, we conducted study on curcumin, a major bioactive compound. Using DAF-FM Diacetate dye, it has been shown that curcumin induced increased nitric oxide generation in *C*. A*lbicans*. Increase in nitric oxide generation was followed by increase in mitochondrial reactive oxygen species (ROS) and was monitored using MitoSOX Red dye. Mitochondrial calcium uptake was also monitored using Rhod-2AM and mitochondrial membrane potential decreased compared to untreated ones when cells were treated with curcumin using JC-1 dye. Moreover, curcumin-treated cells showed increased fluorescence intensity when using MitoTracker Green, which indicates that mitochondrial mass increased after curcumin treatment. Results show that mitochondria in *C*. A*lbicans* do not function normally after treatment of curcumin. Additionally, curcumin displayed membrane depolarization when using $DiBAC_4(3)$. In summary, mitochondrial dysfunction and membrane depolarization are induced after curcumin treatment, contributing in antifungal mechanism in *C*. A*lbicans*. When conducting study, L-NG-Nitroarginine Methyl Ester (L-NAME), which is a NOS inhibitor, was applied in every experiment. In all experiment, L-NAME pre-treated cells blocked the effects

induced by curcumin, which indicates that presence of nitric oxide affects the overall mechanism. In conclusion, curcumin displays antifungal activity in *Candida albicans* mediated by nitric oxide.

Localization of *frequency* mRNA in Biomolecular Condensates Contributes to Period Length Determination in the *Neurospora crassa* Circadian Clock.

B. Bartholomai[1], A. Gladfelter[2], J. Loros[1], J. Dunlap[1]; [1]Geisel School of Medicine at Dartmouth, Hanover, NH, [2]University of North Carolina, Chapel Hill, NC.

Circadian rhythms in animals and fungi are generated by a transcription - translation negative feedback loop. In *Neurospora crassa,* the WCC, a complex of WHITE COLLAR - 1 (WC-1) and WC-2, is the major transcription factor on the positive arm of the clock, while a multi-protein complex nucleated by FREQUENCY (FRQ) acts on WCC to repress its function. This feedback loop requires approximately 24-hours for a complete cycle, and has been extensively studied at the tissue, organismal, and population level for several decades using biochemical and genetic techniques. Spatiotemporal dynamics of core clock molecules at the cellular level, however, have remained elusive. In particular we are interested in the mechanism underlying the approximately 4 hour delay between peaks of *frq* mRNA accumulation and expression of FRQ protein, a delay that contributes to the long 24 hr circadian period length. An additional spur arose from recent extensive circadian transcriptomics and proteomics data that revealed unexpectedly large temporal delays between transcription and translation: a quarter of the proteome is circadianly regulated with a median delay between RNA peak and protein peak of ~10 hrs. We became curious as to how mRNA could be protected from degradation long enough to facilitate these temporal delays. We have identified a novel RNA binding protein that undergoes liquid-liquid phase separation, interacts with *frq* mRNA, and plays a role in the observed perinuclear enrichment of *frq* mRNA*. The* RNA-binding protein shows heterogeneous distribution throughout the cytoplasm and displays dynamic liquid like behavior in live-cell imaging. In knockouts lacking the protein, the heterogeneous perinuclear localization of the *frq* transcript is lost and a significant lengthening of the circadian period is observed. We hypothesize that sequestration of clock related transcripts through phase separation could facilitate local translation and/or protection of transcripts. Additionally, sequestration of circadian mRNA in biomolecular condensates could contribute to temporal delays between mRNA expression and protein accumulation, subsequently affecting the overall temporal mechanism of the clock.

P833/B853

A Polyclonal Sera Against Trimethyl Chitosan Nanoparticles Facilitates Detection of Phytopathogenic Fungi.

H. JOSHI, S. S. Maitra, R. Bhatnagar; Jawaharlal Nehru University Library, New Delhi, INDIA.

Our study aims to provoke tools for the first-line detection of fungal infection in plants or any other fungal contamination in various human consumables. Chitin is one of the most abundant fungal cell wall polysaccharide that's naturally deacetylated to chitosan when the pathogenic fungi infect the host. During infection, this deacetylation process serves to represent the pathogenicity mechanisms to protect the fungi from plant extracellular chitinases because chitosan is a poor substrate for chitinases. This process ramified in the fungal cell wall modulation and plant-pathogen communication. Thusly, detection of chitosan could potentially aid in the detection of fungal contamination. Previous studies have reported that chitosan is a poor immunogen hence, we used trimethyl chitosan nanoparticles

(TMC) as an antigen to enhance the immunogenicity. We used several phytopathogenic fungi strains for the study. Mice were immunized with TMC nanoparticles to generate polyclonal sera. This sera could provide an enhanced humoral immune response and generate a rich & heterogeneous repertoire of antibodies against chitosan & TMC. The binding affinity of the sera with fungal cell wall was analyzed by various techniques such as ELISA, langmuir isotherm, confocal microscopy & ITC (Isothermal Calorimetry) and it was found that the polyclonal sera were able to detect chitosan in the fungal cell wall. Interestingly, it was found that the detection specificity varied among the strains in proportion to the chitin content of their cell wall. In ELISA, *Fusarium oxysporium* was detected with the highest affinity while *Trichoderma ressei* was detected with the least affinity. To ensure specificity and high binding capacity we performed adsorption isotherm & ITC, additionally confirmed by confocal microscopy. The notion of generating this antibody repertoire against chitosan, utilizing a methylated derivative of chitosan as nanoparticles is a novel attempt in the direction of development of detection tools for fungal contamination. The polyclonal antibody repertoire generated & experimentally verified in this study can be applied in quality control assays, in infection detection assays and as a tool to analyze the structure of fungal cell walls. Conclusively, this study could prove to be beneficial in the detection of human fungal pathogens involved in the different fungal infections.

P834/B854

Inhibition of Hsp90 Regulates Fluconazole Resistance in the Pathogenic Fungus *Cryptococcus Neoformans*.

M. Covington, B. Darrah, S. Chandrasekaran; Furman University, Greenville, SC.

Cryptococcus neoformans is an encapsulated yeast, found in the lungs of immunocompromised hosts. In the human host, *Cryptococcus* is subject to multiple forms of environmental stress, including heat stress. Heat shock protein 90 (Hsp90) is an essential protein that has been shown to protect fungal cells against extreme temperature in the human host and to assist in proper cell division. Hsp90 has also been implicated in resistance to the anti-fungal drug fluconazole. To better characterize the role of Hsp90 in fluconazole resistance in *Cryptococcus* we addressed two questions: 1. Does concomitant partial inhibition of Hsp90 and treatment with fluconazole lead to increased sensitivity to fluconazole and 2. Does prolonged partial inhibition of Hsp90 prior to treatment with fluconazole lead to subsequent increase in development of fluconazole resistance. Using growth assays, disk assays, and a standardized e-test to determine the Minimum Inhibitory Concentration (MIC) of fluconazole, we found that indeed, pharmacological partial inhibition of Hsp90 with radicicol, concomitant with fluconazole treatment leads to increased sensitivity to fluconazole. However, initial pre-treatment of *Cryptococcus* with sub-inhibitory concentration of radicicol followed by exposure to fluconazole leads to development of fluconazole resistant *Cryptococcus* colonies. We characterized the resistant colonies, which show a lower MIC to fluconazole compared to cells that were never exposed to radicicol and fluconazole. Cells derived from the resistant colonies exhibit slower growth on drug-free media, and lose resistance to the drug after passaging in drug-free media. Based on the fact that resistance to fluconazole is lost when fluconazole is removed from the environment, we infer that compromising Hsp90 function during the pre-treatment with radicicol triggers aneuploidy in *Cryptococcus neoformans*. Furthermore, we speculate that the resistant colonies are aneuploids that possess an altered chromosome number to maintain drug resistance in response to an environmental insult, such as presence of fluconazole.

P835/B855

Investigating How the Septin Cytoskeleton Controls Morphogenesis in Marine Fungi.

E. J. D. Vogt[1], L. M. Y. Mitchison-Field[1], C. M. Field[2], A. S. Gladfelter[1]; [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Harvard Medical School, Boston, MA.

Complex cell morphologies are attributed to the dynamics and plasticity of the cytoskeleton. An understudied component of this framework is the septin cytoskeleton. Septins are filament-forming, GTP-binding proteins important for coordination of cell cycle progression, actin and microtubule organization, polarized cell growth, and membrane remodeling. Septins were discovered and have been most intensively studied in the budding yeast, *Saccharomyces cerevisiae*. In late G1 of budding yeast, septins form a cortical ring structure near the bud site, and at the time of bud emergence, the ring expands into a rigid septin collar, spanning the whole bud neck and scaffolds other cytokinetic factors. Despite their conserved role in the eukaryotic cell cycle, many aspects of septin assembly and function in cell morphology remain mysterious. To study the biophysical properties of septins in the context of variable cell morphogenesis, we are using a set of species of black yeasts isolated from marine environments surrounding Woods Hole, MA. The marine environment presents a variety of stresses for fungi including high osmotic and oligotrophic conditions, UV exposure, temperature fluctuations and limited substrates that necessitate particular morphological adaptations. To assess morphogenesis and division patterns at the single cell level, we filmed growth using high-magnification, differential interference contrast (DIC) time-lapse microscopy. Our single-cell analyses revealed remarkably distinct morphologies from the conventional model yeasts including multiple simultaneous budding events, division through a combination of budding and fission, and consecutive orthogonal septations. We hypothesize that some of these unique patterns of morphogenesis are linked to intrinsic features of septin polymerization and interactions of septins with downstream effectors. Bioinformatic comparisons of septin sequences show regions of divergence from the conventional yeast models *S. cerevisiae* and *S. pombe* that are conserved in the black yeast species. Many of these residue changes are located within key structural elements, such as the GTPase domain and C-terminal coiled-coil tail. This is interesting as septin oligomeric structures assemble via interactions between these domains; changes in these interactions could influence the biophysical properties of these proteins such as flexibility, annealing, fragmentation, and bundling, which could in turn alter their cellular function. Using comparative analysis of the genome, cell biology and biophysics of septins from these fungi, we can learn how the plasticity the septin cytoskeleton can generate different cell morphologies.

Role of Heat and Oxidative Stress on Sensitivity to Anti-fungal Drugs in the Pathogenic Fungus Cryptococcus Neoformans.

E. Lupinacci, T. Carlson, K. Mosely, C. Pomykata, S. Chandrasekaran; Furman University, Greenville, SC.

Role of heat and oxidative stress on sensitivity to anti-fungal drugs in the pathogenic fungus *Cryptococcus neoformans*

Emily Lupinacci[1], Tyler Carlson[1], Katie Mosely[1], Corbyn Pomykata[1] and Srikripa Chandrasekaran[1] [1]Department of Biology, Furman University, Greenville, SC *Cryptococcus neoformans* is an opportunistic pathogen, infecting the lungs of immunocompromised patients, which can further lead to cryptococcal meningitis. The fungistatic drug, fluconazole (FLC), and the fungicidal drug, Amphotericin B (AmpB), are used to treat cryptococcal infections. While FLC inhibits cells by lowering the production of ergosterol, AmpB kills the cells by binding to ergosterol and permeabilizing

plasma membrane. AmpB and to a lesser extent also FLC have been implicated in generating increased levels of Reactive Oxygen Species (ROS), thereby contributing to the inhibition of *C. neoformans*. We wanted to understand how the sensitivity of *C. neoformans* to FLC and AmpB is influenced in the presence of oxidative, heat and nutrient stress. We grew *C. neoformans* in rich media such as YPD (Yeast Peptone Dextrose broth) or poor media such as YNB (Yeast Nitrogen base) in the presence and absence of various antioxidants and at varying temperatures. We found increased sensitivity to FLC at increasing temperatures but no effect of high temperature on the sensitivity of *C. neoformans* to Amp B. The antioxidants RA, AA, and PDTC, but not GSH, could rescue *C. neoformans* from FLC sensitivity, while only GSH (not RA, AA, PDTC) could rescue *C. neoformans* from sensitivity to AmpB. *C. neoformans* showed increased sensitivity to FLC and moderate sensitivity to AmpB in rich medium (YPD), while under poor nutrient conditions (YNB), *C. neoformans* showed higher sensitivity to AmpB and decreased sensitivity to FLC. Our results indicate that sensitivity of *C. neoformans* to FLC v/s AmpB varies under different environmental conditions. This difference in sensitivity could be due to contrasting role ergosterol plays in the molecular responses elicited by *C. neoformans* in the presence of either AmpB or FLC.

Defining Therapeutic Targets and New Therapeutics 1

Retina Specific Laminins Model Interphotoreceptor Matrix to Drive Differentiation of Photoreceptors from Human Pluripotent Stem Cells.

H. Tay[1], A. Kvanta[2], H. An dre[2], A. Moreno-Moral[1], Z. Cai[1], W. Tan[1], J. Guo[1], E. Petretto[1], K. Tryggvason[1]; [1]Duke-NUS Medical School, Singapore, SINGAPORE, [2]Karolinska Institute, Stockholm, SWEDEN.

Visual cycle is dependent on the functional interplay between retinal pigmented epithelium (RPE) and photoreceptors. Therefore, photoreceptors offer promising role in retinal cell therapy for treatment of retinal diseases that involve loss of these cells such as Aged Macular Degeneration (AMD). The light sensitive photoreceptors are anchored on the monolayer RPE with the support of specific laminin isoforms. At least 16 laminin isoforms (LN) present in the human extracellular matrix, play specific roles on diverse cellular differentiation and phenotype stability. Most recently, LN-221 and LN-511 have been demonstrated for robust hESC- cardiomyocyte differentiation and expansion of human epidermal keratinocytes respectively. We currently show that the inter-photoreceptor matrix could be modeled by using retina specific laminin isoforms; LN-523 and LN-521. This mimetic retina matrix like surface has shown to promote the differentiation of hESCs into photoreceptor progenitors in a simplified two steps protocol. Our single cell transcriptome analysis shows that the photoreceptor markers including rod and cone precursors; CRX, RCVRN, NRL and Pde6H are expressed in the differentiated photoreceptors as early as Day 30. The specific differentiation time points recapitulate the step wise in *vivo* retinogenesis. Since this approach is not dependent on the formation of retinal organoids and devoid of manual excision and re-plating, the reproducibility between retinal differentiation batches is very high. The functional role of the engrafted hESC- derived photoreceptor progenitors in the post-transplanted eyes after 1 month show synaptic connectivity into the rabbit host tissue. In conclusion, this retinal organoid free method robustly drives the hESC differentiation to the photoreceptor progenitor lineage, suggesting that retina specific laminin play functional role during early human retinal development. Most importantly, we have shown the feasibility and efficacy of using these laminin based differentiated cells for transplantation in the large eyed pre-clinical model. This xenogen free and chemically defined

method may constitute an important step towards clinically safe and functional hESC- derived photoreceptors to treat vision loss.

P838/B859

Quantitative Surface Proteomics in Retinal Pigment Epithelium Reveals Novel Cross-talk Pathway Inhibitory of Choroidal an giogenesis.

P. S. Caceres[1], C. Hanke-Gogokhia[1], M. Ridano[2], E. Rodriguez-Boulan[1]; [1]Weill Cornell Medical College, New York, NY, [2]National University of Cordoba, Cordoba, ARGENTINA.

Background: the retinal pigment epithelium (RPE) is polarized into apical and basolateral plasma membrane domains, which interact with photoreceptors and the underlying choroidal blood vessels respectively. Dysfunction of the RPE causes photoreceptor degeneration during age-related macular degeneration (AMD), the leading cause of blindness in the elderly. There is a need to develop treatments for AMD since most cases cannot be cured. Only a subtype, “wet” AMD, can be treated by blocking vascular endothelium growth factor (VEGF), which is produced in excess by the RPE and causes choroidal blood vessels to proliferate and leak. However, anti-VEGF treatments can develop resistance and cause adverse side effects. Objective: to identify cross-talk pathways between the RPE and choroid that could provide targets for more effective treatment of AMD. Methods: We developed a quantitative surface proteomics approach to survey the apical and basolateral surfaces of RPE primary cultures. We identified targets of interest in angiogenesis via bioinformatics and used CRISPR to test their role in angiogenesis measured as sprouting from choroid explants. We performed intravitreal and subretinal injections to measure choroidal neovascularization induced by matrigel in mice. Results: the polarized surface RPE proteome revealed basolateral receptors and cell-cell communication proteins. We identified receptors and ligands of the plexin and semaphorin families respectively. We confirmed the presence of Semaphorin-4A (Sema4A) in RPE, and Plexin-D1 in choroid (mouse) since this Sema-Plexin pair regulates angiogenesis in other systems. To test whether Sema4A produced by the RPE inhibits choroid angiogenesis, we knocked-out Sema4A in cultured RPE cells and measured their ability to stimulate angiogenesis in co-culture with choroid explants. We found that Sema4A knockout RPE cells had an enhanced capacity to stimulate choroid angiogenesis, indicating a baseline inhibitory role of Sema4A. Finally, we found that exogenous recombinant Sema4A prevented VEGF-induced angiogenesis in choroid explants, and reduced matrigel-induced choroidal neovascularization in vivo. Conclusion: Sema4A is an anti-angiogenic protein secreted by the RPE that inhibits choroidal neovascularization. These results highlight the potential of RPE-choroid cross-talk via Sema-Plexin signaling to counteract the angiogenic effect of VEGF during AMD.

P839/B860

Retinoschisin Protein Therapy for X-linked Retinoschisis Using a Novel Drug Delivery System.

J. Arunachalam[1], A. UR[2], K. Verma[2], R. Rajendran[1], S. Chidambaram[3]; [1]Central Inter-Disciplinary Research Facility, Pondicherry, INDIA, [2]UR an oop Research Group, Pondicherry, INDIA, [3]Pondicherry University, Pondicherry, INDIA.

Background and Objective: X-linked retinoschisis (XLRS) is an inherited retinal degenerative disease caused by mutations in the RS1 gene that leads to splitting of the neurosensory retina resulting in reduced visual acuity in affected patients. RS1 gene encodes a secretory retinoschisin protein implicated in cell-cell interactions and adhesion between photoreceptors and bipolar cells of the retina and also

reported to be expressed in pineal gland for its unexplored role. The prevalence of the disease is 1 in 10,000 worldwide and leads to poor quality of life. Till now, there is no cure for this disease and prophylactic treatment has not been beneficial which often results in severe long term vision-threatening complications. On the other hand, protein replacement therapy holds a lot of promise for oculogenetic diseases. However, the challenge is to deliver the protein effectively, in a stable formulation with maximum availability at the target site of action. Therefore, the study aimed to test the efficacy of retinoschisin delivery using a novel drug delivery device and method for controlled and continuous delivery of drugs through the respiratory mucosa in the maxillary sinus bypassing the blood-brain barrier in mice towards protein therapeutics for XLRS. **Methodology:** Recombinant retinoschisin protein with N-terminal 6xHis tag and lignocaine as control drug were administrated directly into the connective tissue of the maxillary sinus mucosa using the device through an incision made over the nasal bone in wild type mice. Retinal tissue along with brain, liver and serum of the treated mice were processed and analyzed by reversed-phase high-performance liquid chromatography (HPLC) for assessment of delivery. **Results:** the injected retinoschisin protein and the lignocaine drug were rapidly absorbed from the delivery site through the neural lymphatic and vascular route. Significant levels of the protein and drug were detected in the retina as well as in brain within 15 mins, whereas, the bioavailability in liver and serum was undetectable substantiating no systemic leakage. Further histopathological examination of the tissues proved that the delivery modality did not show any toxicity in the treated mice. **Conclusion:** Taken together, these data suggest that the investigated retinoschisin protein therapy can offer effective protein replacement treatment technique for XLRS as an alternative to gene therapy. With more optimized nanoformulation for retinoschisin protein and targeted delivery, the study may open up new prospects to improve the treatment regimen of retinoschisis. Upon successful outcome, this potentially advantageous protein therapeutic approach could be extrapolated to other retinal dystrophies and also to brain disorders.

P840/B861

Preventive Effect of Dopamine on Hyperglycemic Memory-induced Vascular Leakage in the Retina of Diabetic Mice.

Y. Lee[1], J. Lee[1], H. Jeon[1], K. Ha[1,2]; [1]Kangwon national university, Chun cheon, KOREA, REPUBLIC OF, [2]Scripps Korea antibody Institute, Chuncheon, KOREA, REPUBLIC OF.

The occurrence of hyperglycemic memory (HGM) is recognized as a phenomenon related to the persistent effects of diabetic vasculopathies even after adequate handling of glycemia. The notion of 'memory' is define that the hyperglycemic environment can be remembered in the vascular system. However, the cause of the hyperglycemic memory phenomenon is unclear. We investigated potential candidate underlying the pathogenesis of diabetic retinopathy via a HGM phenomenon. Our results indicated that it can be predicted low levels of dopamine by reducing tyrosine hydroxylase (TH), a marker for dopaminergic neurons, in the retinas both of diabetic and HGM mice. Although a reduction in dopamine content has been observed in diabetes, its effects in the development of HGM phenomenon-induced retinopathy remains unknown. We found that dopamine prevents HGM phenomenon-induced intracellular events including inflammation, apoptosis and vascular permeability in the human retinal endothelial cells and in the retinas of HGM mice. Our findings suggest that dopamine is a potential drug for treating HGM induced diabetic retinopathy.

Mesenchymal Stem Cells Attenuate Diabetic Kidney Disease through Nadph Oxidases Dependent Mechanism.

R. Jurjus, A. Eid, R. Njeim, A. Jurjus; American University of Beirut Dept. Of an atomy Cell Biology and Physiology, Beirut, LEBANON.

Objective: Diabetic kidney disease (DKD) is one of the major complications of diabetes. Diabetes, among several pathological conditions, alters the redox balance resulting in oxidative stress. The major intracellular sources of reactive oxygen species (ROS), including NADPH oxidases (NOX), specifically NOX 4, previously known as RENOX, cytochrome P450s of the 4A family (CYP4A) and its metabolite 20-HETE, have been shown to be implicated in the pathogenesis of DKD. An emerging body of evidence has revealed that stem cells treatment improves acute tubular injury and induces glomerular repair. However, this mechanism of repair has not yet been identified. This study aims to determine the effect of mesenchymal stem cells (MSCs) treatment on oxidative stress, and to investigate the mechanistic pathway by which MSCs attenuate renal injury.Materials and Methods: Sprague-Dawley rats were divided into two groups: a control group and a streptozotocin-induced type 1 diabetic group each treated with either saline, MSCs-derived medium, or $1x10^6$ MSCs. All injections were administered intravenously. After eight weeks of treatment from diabetes onset, functional, histological and biochemical parameters of the kidneys were assessed. Dihydroethidium (DHE) stain was used to determine ROS production levels. Real-time Reverse Transcription-Polymerase Chain Reaction (RT-PCR) and Western blotting were performed to determine mRNA levels and protein expression of fibronectin, laminin, Nox4, and TGF-β. The histopathological alterations were assessed using PAS and Masson Trichrome stains.Results: MSCs treatment restored normal urinary albumin excretion levels. Protection against DKD imparted by MSCs was indicated by decreased glomerulosclerosis and tubulointerstitial fibrosis. Moreover, MSCs treatment attenuated tubulointerstitial changes observed in the diabetic milieu. The expression of fibronectin and laminin was significantly decreased in MSCs-treated diabetic rats compared to vehicle-treated diabetic rats. A reduction in oxidative stress was also paralleled by a decrease in the NADPH oxidases activity, NOX4 mRNA and protein expression. TGF- β expression known to mediate cellular hypertrophy and stimulate extracellular matrix biosynthesis in diabetes mellitus was also decreased in the diabetic treated animals.Conclusion: Our results suggest that MSCs have a potential therapeutic effect in the treatment of DKD by attenuating NADPH oxidases-induced ROS production.Keywords: *Diabetic Kidney Disease, Mesenchymal stem cells*, *NOX4,* TGF- β, ROS

Apolipoprotein A-IV Improves Glucose Homeostasis by Acting on Islets and Reprogramming Intestinal Epithelial Cells.

Z. Cao; Chinese Academy of Sciences, Beijing, CHINA.

Roux-en-Y gastric bypass surgery (RYGBP) is one of the most effective procedures for the treatment of severe obesity and type 2 diabetes mellitus (T2DM). The underlying mechanism for the improvement of glucose homeostasis remains unknown. We found that apolipoprotein A-IV (apoA-IV) was significantly increased in patient serum after RYGBP by proteomic analysis and Western blot. The intraperitoneal glucose tolerance test (IPGTT) had been improved dramatically in apoA-IV-treated diabetic animal models (i.e., GK rats, ob/ob mice, and db/db mice). In addition, the hyperglycemia was ameliorated remarkably in apoA-IV-overexpressed ob/ob mice transfected with adeno-associated virus (AAV).

Notably, the serum high-density lipoprotein (HDL) concentration was higher compared with the control group, while low-density lipoprotein (LDL) was lower. To determine possible regulation of apoA-IV expression, we constructed a screening system using CRISPR/Cas9 technology for searching compounds that regulate the apoA-IV expression. We found that glucose upregulated apoA-IV expression in the system. Importantly, we identified that apoA-IV promoted insulin release in two ways under high glucose stimulation condition. One was that apoA-IV directly acted on islets to stimulate insulin secretion, and was also effective on isolated human islets. The other is that IEC6 cells, intestinal epithelial cell, may be reprogramed to β-like cells through upregulating PDX1 expression to release insulin. These results shed light on the functions of apoA-IV in improving glucose homeostasis and provide evidence that apoA-IV may serve as a promising drug for treating diabetes and cardiovascular disease.

Tissue-restricted AMPK Over-expression Mitigates Disrupted Glucose Metabolism in a *Drosophila* Model of Cardiometabolic Disease.

M. Sumathipala, M. Viswanathan, A. Blice-Baum; Johns Hopkins Medical School, Division of Cardiology, Baltimore, MD.

A worsening global health crisis, cardiometabolic disease involves disrupted lipid and glucose metabolism across adipose, muscle, and cardiac tissue. AMP Kinase (AMPK) is a major regulator of key CMD pathways, such as oxidative stress, fatty acid oxidation, and glucose metabolism. It regulates energy metabolism in adipose tissue, the major lipid repository, and in skeletal muscle, where 80% of glucose uptake occurs. While the protective role of AMPK in CMD has been suggested, AMPK's molecular mechanisms in specific tissues affected by CMD remain poorly understood. We investigate the ameliorative effects of tissue specific AMPK overexpression in a diet-induced *Drosophila* model of CMD. Tissue specific expression of AMPK in striated muscle and in adipocytes is acheived by crossing GAL4 driver lines to a UAS-AMPK line, and to a w^{118} background line as a control. To assess cardiac function and structure, we perform semi-intact cardiac tube preparations followed by analysis of beating heart videos to quantify functional parameters and immuno-staining. We also assess hemolymph glucose levels via enzymatic assay, thoracic muscle structure via bisection and immuno-staining, and lipid accumulation via Nile Red staining. Cardiometabolic dysfunction-higher heart rates and arrhythmicity, lower diastolic/systolic ratio, higher hemolymph glucose levels, and abnormal cardiac structure-was induced with a high-fat (HF) or high-sugar (HS) diet, and verified against controls on a normal diet. AMPK over-expression in muscle decreased glucose by 82%; over-expression in adipocytes decreased glucose by 65%, relative to controls on the same HF and HS diet ($p<0.05$). AMPK in muscle mitigated skeletal muscle atrophy and disarray, contributing to improved flight ability. It ameliorated cardiac dysfunction: diastolic/systolic ratio increased 111%, arrhythmicity decreased 67%, and heartrate decreased 37% ($p<0.05$). Qualitatively, both AMPK in muscle and in adipocytes decreased lipid accumulation in adipocytes surrounding the heart and preserved myocardial structure. These findings implicate AMPK in ameliorating diet-induced disruptions to lipid and glucose metabolism, cardiac function, and cardiac structure: likely mediated through its role as a master regulator in metabolic pathways, warranting further investigation into the AMPK pathway in CMD as a promising therapeutic avenue.

P844/B865

Evaluation of the Impact of *Shpk* Elimination on Macrophage-mediated Hematopoietic Stem and Progenitor Cell Transplantation Therapy for Cystinosis.

M. KHAN, 92122[1], S. Goodman[1], I. Gertsman[2], J. Sharma[1], S. Cherqui[1]; [1]University of California, San Diego, La Jolla, CA, [2]Clarus an alytical, San Diego, CA.

Cystinosis is an early onset lysosomal storage disorder caused by mutations of the *CTNS* gene and characterized by the defective export and subsequent accumulation and crystallization of cystine within lysosomes. Since *CTNS* is ubiquitously expressed, cystinosis presents as a multi-systemic disorder with symptoms ranging from renal dysregulation to abnormalities in the eye, muscle, and thyroid, ultimately leading to premature death. Previous studies found that hematopoietic stem and progenitor cell (HSPC) transplantation into *Ctns*$^{-/-}$ mice prevents disease progression via HSPC-derived macrophage-mediated delivery of functional lysosomes to diseased cells. While Phase I/II clinical trials for this therapy are underway, one potential complication is that roughly 40% of patients with cystinosis carry the 57-kb homozygous deletion eliminating *SHPK* in addition to *CTNS*. *SHPK* is a Pentose Phosphate Pathway (PPP) metabolic enzyme found to directly modulate macrophage polarization. Taking into account that the mechanism of our stem cell-based therapy relies upon macrophages, understanding if it requires *SHPK* holds clinical relevance as it helps elucidate if patients carrying the 57-kb deletion at the homozygous state are likely to benefit from the therapy. To address this question, we studied the impact of *Shpk*$^{-/-}$ HSPC donors on disease rescue following transplantation into *Ctns*$^{-/-}$ recipient mice. We generated and characterized the first *Shpk*$^{-/-}$ mouse model at the genomic, RNA, and protein levels. Mass spectrometry revealed a metabolic phenotype observed as dysregulation of PPP metabolites in *Shpk*$^{-/-}$ livers, while RNA quantitation also showed changes in macrophage polarization markers by cultured primary bone marrow-derived macrophages (BMDMs). We then transplanted *Shpk*$^{-/-}$ HSPCs into lethally-irradiated *Ctns*$^{-/-}$ mice and evaluated transplantation efficacy. We found that *Shpk*$^{-/-}$ HSPCs were effective in the restoration of *Ctns* expression and reduction of cystine levels across multiple *Ctns*$^{-/-}$ tissues as compared to negative *Ctns*$^{-/-}$ HSPC controls. Renal function was also improved in the *Shpk*$^{-/-}$ HSPC-transplanted *Ctns*$^{-/-}$ mice as opposed to the *Ctns*$^{-/-}$ HSPC-transplanted mice. In conclusion, our studies demonstrate that *Shpk*$^{-/-}$ HSPCs may benefit all patients regardless of *SHPK* genotype, confirming that our novel HSPC therapy remains effective at preventing cystinosis.

P845/B866

Upgrading and Characterization of Heart Homing Peptides for Therapeutic Delivery in Cardiomyocytes.

C. DEFLERS[1,2], A. LE FEVRE[3], F. PUECH[2], G. PIDOUX[4], R. FISCHMEISTER[1]; [1]Paris Saclay University, Châtenay-Malabry, FRANCE, [2]Sanofi Recherche et Développement, Integrated Drug Discovery, Chilly Mazarin, FRANCE, [3]Sanofi Recherche et Développement, Translational Sciences, Chilly Mazarin, FRANCE, [4]Inserm UMR-S 1180, Châtenay-Malabry, FRANCE.

Cardiovascular diseases represent the major cause of death in western industrialized countries. In particular, 50% of heart failure patients die within 5-years. Although usual treatments exist (*e.g.* β-blockers, mineralocorticoid receptor antagonists), they impact the quality of life due to side effects and off-targets. Thus, targeting specifically cardiomyocytes for drug delivery would certainly represent an improvement over classical ways of administration. Interestingly, two peptides were previously described to exhibit a preferential cardiac tropism (*i.e.* CTP: APWHLSSQYSRT and PCM:

WLSEAGPVVTVRALRGTGSW). However, CTP and PCM peptides efficacy in terms of cell penetration remains low and to our knowledge no optimization has been reported. The aim of this work was to optimize original CTP and PCM peptides and to characterize their respective uptake efficacy and cytotoxicity in cardiomyocytes. Peptide design strategies were carried out (*e.g.* substitution and retro-inverso analysis, cyclization and conjugation to macromolecules or polymers sequences). Over 80 different CTP- and PCM-derived peptides coupled with 6-carboxyfluoresceine (6-CF) were developed. All constructs were assessed for cellular uptake in neonatal rat ventricular cardiomyocytes (NRVC). Cellular uptake efficacy and corresponding viability were quantified by flow cytometry as percentage of 6-CF-positive cells. Staining with fluorescence-based Invitrogen LIVE/DEAD probe was used to evaluate cytotoxicity. Two of the derived peptides, 6-CF-CTP1 and 6-CF-PCM2, exhibited, respectively, a 6.5- and 5.5-fold increase over original 6-CF-CTP and 6-CF-PCM sequences in live cellular uptake. None of the original or derived 6-CF-CTP and 6-CF-PCM-peptides exhibited cytotoxicity when tested at concentrations ranging from 1 to 50 µM. We also performed 4°C incubations which did not prevent the NRVC uptake, excluding an energy-driven process. By high content imaging experiments, we show that these 6-CF- original and derived peptides localized in the cytoplasm. In addition, we are going to identify their location by counterstaining cellular compartments. An alysis will be achieved by confocal microscopy. This study displays potential for optimization of the CTP or PCM peptide sequences to increase their cellular uptake efficacy without cytotoxicity. It raises the potential use of heart targeting peptides for cardiac drug delivery.

P846/B867

Silibinin Administration Ameliorated Pulmonary Arterial Hypertension in a Rat Disease Model.

N. Kawaguchi[1], T. Zhang[1], K. Tsuji[2], E. Hayama[1], Y. Furutani[1], T. Nakanishi[1]; [1]Tokyo Women's Medical University, Tokyo, JAPAN, [2]Tokyo Medical and Dental University, Tokyo, JAPAN.

Background: the pathogenesis of pulmonary arterial hypertension (PAH) involves endothelial dysfunction, chronic inflammation, smooth muscle proliferation, and pulmonary arteriolar occlusion, and no effective treatment to treat its pathogenesis has been discovered. We previously reported that C-X-C chemokine receptor type 4 (CXCR4) expression in the pulmonary artery (PA) was enhanced (Experimental and Therapeutic Medicine 2018). Therefore, we hypothesized that silibinin, a CXCR4 inhibitor, may decrease PA pressure in the rat PAH model. **Purpose:** We investigated the following hypotheses: 1) CXCR4+ cells migrate to the injured tissue from the bone marrow through the stromal derived factor (SDF-1)/CXCR4 axis, in which SDF-1 is a ligand of CXCR4, and CXCR4+ cells may contribute to the development of PAH. Thus, silibinin administration may improve the pathogenesis of PAH. 2) If CXCR4 is involved in its pathogenesis, silibinin may affect the cells in the bone marrow, as CXCR4+ cells rest in the bone marrow with binding to the niche cells, which are known to express SDF-1. **Methods:** We established a rat PAH model by injecting monocrotaline and maintaining a hypoxic (10% oxygen) environment. Silibinin was suspended in 0.5% carboxymethyl cellulose (CMC). Silibinin or CMC was given orally every day for 5 weeks. We examined the gene and protein expression levels of CXCR4 and other stem cell markers in the PAs by reverse transcription quantitative polymerase chain reaction (RT-qPCR) and immunohistochemistry each week. We further examined CXCR4 expression in cultured bone marrow cells using RT-qPCR and flow cytometry after 2 weeks of treatment. **Results:** During PAH development, especially in the early stage, silibinin had a treatment effect on PAH development. The CXCR4 gene expression in the PA was also suppressed by the silibinin treatment. However, the gene expression level of CXCR4 was upregulated in the cultured bone marrow cells. The cell population of the

CXCR4+ cells in the cultured bone marrow cells was also increased by the silibinin treatment. Such changes were not observed in the PAH model rats without silibinin treatment. **Conclusion**: Taken together, silibinin can be used as a medicine for PAH. The decrease of CXCR4+ cells in the PA is considered to lead to PAH amelioration. The present study suggests that silibinin affects not only the pulmonary tissue but also the cells in the bone marrow. How and to what extent the effect of silibinin in the bone marrow affects PAH remains unclear.

P847/B868

Therapeutic Potential of Metformin in Novel COPD Mouse Model with Diffuse-type Emphysema.

R. Nakashima[1], H. Nohara[1,2], S. Kamei[1,2], H. Fujikawa[1,2], K. Maruta[1], T. Kawakami[1], Y. Eto[1], N. Takahashi[1], A. Nasu[1], M. A. Suico[1], H. Kai[1], T. Shuto[1]; [1]Department of Molecular Medicine, Graduate School of Pharmaceutical Science, Kumamoto University, Kumamoto, JAPAN, [2]Program for Leading Graduate Schools "HIGO (Health Life Science: Interdisciplinary and Global Oriented) Program", Kumamoto, JAPAN.

Chronic Obstructive Pulmonary Disease (COPD) is a refractory respiratory disease mainly characterized by inflammation, cellular senescence, emphysema and lung dysfunction. Although COPD will be the 3rd leading cause of death in the world by 2030, there is no effective treatment for it. Previously, we have established a novel COPD mouse model, that overexpresses airway-specific epithelial Na^+ channel β subunit (βENaC-Tg) (*Sci Rep.* 2016). However, the usability of βENaC-Tg mice compared with existing COPD mouse models (*e.g.* elastase-induced COPD model) is unexplored. First, to evaluate the histological differences, we developed whole lung image-based quantification for histological analysis. We found that βENaC-Tg showed homogeneous emphysema in the whole lung. Next, we estimated the biochemical differences in both models. Interestingly, we found that βENaC-Tg mice, but elastase-induced COPD mouse model, exhibited changed mRNA expression of inflammatory and senescence-related markers at emphysema-manifestation stage. We demonstrated that βENaC-Tg mice exhibit diffuse-type emphysema with stable expression of inflammatory and senescence-like markers compared to elastase model (*J Phamacol Sci.* 2019). We next verified the therapeutic potential of metformin. In our previous study, we showed that high fat diet-induced type 2 diabetes exacerbates the COPD phenotype and advocated the concept of "pulmonary insulin resistance". Therefore, metformin, a clinically available anti-diabetic drug that is known to improve insulin resistance, could have therapeutic potential for COPD. Administration of metformin (free-drinking water) ameliorated pulmonary emphysema and respiratory function (Compliance, Elastance, forced expiratory volume % in 0.1 second) in βENaC-Tg mice. Next, we examined the effect of metformin on ENaC activity using β/γENaC-overexpressing airway epithelial cells. We showed that metformin suppressed ENaC activity. Therefore, our data imply that metformin could be a novel drug for COPD through the suppression of ENaC. Taken together, these data show the usability of βENaC-Tg mice as a diffuse-type emphysema model and confirm the therapeutic potential of metformin for COPD.

P848/B869

Contribution of the Inflammatory Response during Trauma to Endothelial Cell Permeability.

D. Brown, V. Chaplin, R. Paredes, M. Salas, G. Pratt, V. Moreno, N. McNeal, J. Glaser; NAMRU-SA, Fort Sam Houston, TX.

Background: Blood loss during trauma resulting in hemorrhagic shock (HS), induces a myriad of physiological responses in the vasculature, leading to endothelial barrier disruption. Endothelial rupture

releases components that magnify the inflammatory response initiated by trauma. If unregulated, the loss of physiological homeostasis can become increasingly deleterious, inducing multiple organ failure and dysfunction, and/or death. Herein, we utilized endothelial cell adhesion and permeability as markers to assess a model for therapeutic treatments that can alleviate or counteract endothelial damage in inflammatory conditions. **Methods:** Human endothelial cells were seeded at two different densities on an electrode-covered E-Plate96 for cell impedance assays. Following 24 hr. Of growth and 1 hr. serum starvation, cells were treated with either media (control), or with varying concentrations (10-30%) of different treatments including lactated ringers (LR), banked porcine baseline serum (BSLN), or banked porcine trauma serum (TM). Continuous cell impedance was recorded for 24 hr. with the xCELLigence® RTCA SP System. Additionally, endothelial cells seeded on Transwell® inserts were used to determine cell permeability following similar treatments; barrier integrity was measured by FITC-Dextran 40KDa. **Results:** Cell index from endothelial cells treated with 10% and 30% TM serum sharply decreased, while the cell index of those treated with the same percentages of BSLN serum remained stable for a longer period of time. Moreover, the sharp cell index decrease observed in cells treated with TM serum occurred much quicker (50hr) compared to BSLN serum (57hr) or LR treatment. Cell permeability indicated that control cells retained barrier integrity, while cells exposed to LR or TM serum leaked dye to the lower chamber, suggesting disruption of the cellular membrane. **Conclusions:** Data from cell impedance and permeability suggest that the components present in serum following trauma disrupt endothelial cell attachment by destruction of cell adhesion properties or cell death. We will continue developing assays to better model HS in *vitro,* evaluate its effect on cellular populations and evaluate potential therapeutics which target inflammatory components to determine their protection of the endothelial barrier. Candidate therapeutics will be further tested in animal models.

P849/B870

Protease Activated Receptor 2 (PAR_2) Expressed on Myeloid Cells Mediates Histaminergic Itch in Male Mice.

H. S. Jeong, L. R. Barron, V. Lai, B. N. Nottingham, D. M. R. Jenkins, **M. D. Burton**; University of Texas at Dallas, Dallas, TX.

It is known that Protease-activated receptor type 2 (PAR_2) mediates pain and itch through specific action on sensory neurons; here we have shown that myeloid cells expressing PAR_2 are involved in itch responses. Using a novel PAR_2 floxed genetic model, we created a cell specific knockdown of PAR_2 in Lysozyme M $(LysM)^+$ cells, crossing LysMcre and PAR_2 floxed animals ($LysMcre^{+/-}$:$PAR_2^{fl/fl}$). $LysMcre^+$ cells that express PAR_2 are neutrophils, macrophages/monocytes, and mast cells. Flow cytometric analysis from isolated peritoneal cavity and bone marrow immune cells from transgenic animals showed that $LysMcre^{+/-}$:$PAR_2^{fl/fl}$ macrophages and mast cells had significantly reduced expression of PAR_2 in male and female animals, validating our genetic model. We then tested the hypothesis that PAR_2 specifically on $LysM^+$ cells mediated pain and itch in mice. After an intraplantar injection of the PAR_2 agonist, 2-aminothiazol-4-yl-LIGRL-NH_2 (2-at), we observed that mechanical hypersensitivity was no different in subjects lacking PAR_2 on myeloid cells when compared with control littermates, leading us to conclude that direct activation of PAR_2 via 2-at on myeloid cells is not important for mechanical hypersensitivity. We also confirmed that direct PAR_2 activation itself does not cause itch: animals that received an intradermal injection of 2-at did not exhibit an itch response. However, PAR_2 plays a sex-specific role in mediating histaminergic itch in males only. Specifically, itch after mast cell degranulation precipitated by an intradermal dose of compound 48/80 administration. Male mice with PAR_2 knocked down in LysM

cells exhibited a significantly reduced number of scratch bouts. Our findings suggest a novel interaction between mast cell degranulation and PAR_2 on myeloid cells in male animals. Together, these studies represent an important loss-of-function approach to further improve our mechanistic understanding of PAR_2 modulation of pain and itch in the nervous system. This work begins to reveal new mechanistic insight that will have an impact on the design of therapeutics targeting this system.

P850/B871

***In Situ* Immunodetection of Activated Par-2 in Human Skin Reflects Barrier-disrupting Effects of Scratching and Exogenous Protease Activity.**

S. Denda[1], K. Yamasaki[2], H. Terui[2], S. Aiba[2], M. Denda[1]; [1]Shiseido Global Innovation Center, Yokohama, JAPAN, [2]Department of Dermatology, Tohoku University Graduate School of Medicine, Sendai, JAPAN.

Protease-activated receptor-2 (PAR-2) plays an important role in epidermal inflammation and permeability barrier homeostasis. Activation of PAR-2 by proteolytic cleavage at the N-terminus leads to intracellular calcium increase and inflammatory cytokine production. In the granular layers of the epidermis, the calcium increase inhibits lamellar body secretion and delays recovery of the skin's permeability barrier function. In atopic dermatitis, the itch-scratch cycle is the main reason for the exacerbation of the disease. Exogenous proteases, such as dust mite allergens, can easily penetrate the skin after scratching, or if the barrier function is otherwise impaired. On the other hand, the stratum corneum and epidermis contain serine proteases such as KLK14, which is increased in inflamed epidermis. The aim of this work was to examine the roles of endogenous and exogenous proteases in barrier disruption by evaluating the PAR-2-activating effects of scratching and of topical protease (trypsin) application on human skin. For this purpose, we employed immunohistochemistry using an antibody that specifically recognizes N-terminally cleaved (activated) PAR-2. In all cases, positive staining was detected only in the uppermost layer of the epidermis, in the first layer of the stratum granulosum, suggesting prolonged activation of PAR-2 by proteases in the stratum corneum or from external sources. Using ex vivo human skin, we compared the levels of activated PAR-2 in skin sections before and after scratching or topical application of trypsin. Increased immunoreactivity of the N-terminally cleaved form of PAR-2 was observed, confirming that both treatments activate PAR-2. This method might be useful to evaluate the inflammatory status of the skin in patients with atopic dermatitis or similar skin disorders.

Collaborative Development of Therapeutics for Sialic Acid Storage Disease.

M. E. Hackbarth[1], M. Huizing[1], M. C. V. Malicdan[1], D. R. Adams[1], K. Dobrenis[2], M. Wasserstein[3], W. A. Gahl[1], S. U. Walkley[2]; [1]NHGRI, Bethesda, MD, [2]Albert Einstein College of Medicine Department of Neuroscience, Bronx, NY, [3]Children's Hospital at Montefiore, Albert Einstein College of Medicine, Bronx, NY.

Lysosomal sialic acid (SA) storage disease (SASD) is an autosomal recessive, neurodegenerative, multisystemic disorder caused by defects in the lysosomal SA membrane carrier *SLC17A5* (Sialin). SLC17A5 defects cause free SA and secondary metabolites to accumulate in lysosomes. The clinical spectrum ranges from severe infantile onset in infantile sialic acid storage disease (ISSD; elevated urine SA; ~40 reported cases), to a mild, adult form, called Salla disease (moderate elevation of urine SA; ~120 cases). Although sialic acid metabolism, membrane transport, and lysosomal biology have been extensively studied, the pathobiology of SASD remains poorly understood. Moreover, SASD is likely

underdiagnosed; known patients have experienced a diagnostic delay due to the rarity of the disorder, non-specific clinical symptoms and absence of routine urine SA testing. There is no approved therapy for SASD. As is typical for orphan diseases, the small population of patients makes it difficult to motivate industries to invest in performing the pre-clinical and clinical studies necessary to develop therapies. On the other hand, multidisciplinary collaborative efforts involving the NIH, academic clinical scientists, and patient advocacy groups have successfully overcome the scientific, clinical and financial challenges facing the development of new drug treatments for rare diseases. Encouraged by these successes, we have initiated a collaborative effort for SASD. This has allowed us to start creating cell and mouse models, perform basic/translational research, initiate a natural history study to aid in the identification of biomarkers and treatment endpoints, raise awareness for SASD, and investigate leads on drug candidates. We aim to collect data that incentivize industry to further develop, obtain approval, and commercialize SASD treatments.

P852/B873

Biophysical/biochemical Characterization of the Human Chitooligosaccharide Deacetylase.

S. LEE[1], B. Lee[2]; [1]The national cancer center graduate school of cancer science and policy (NCC-GCSP), Goyang, KOREA, REPUBLIC OF, [2]National Cancer Center (NCC), Goyang, KOREA, REPUBLIC OF.

The human chitooligosaccharide deacetylase (HCD), belongs to the carbohydrate esterases family 4 (CE4), is found in various organisms from bacteria to human. Putatively, the HCD catalyzes the deacetylation of acetylated carbohydrates and has been considered to play an important role in the degradation of oligosaccharides. It has been known that the HCD is involved in several inflammatory diseases including ulcerative colitis, psoriasis, and Crohn's disease. Recently, it was also revealed that the HCD is involved in pathological progress of lung cancer such as invasion and migration. Therefore, inhibition of this enzyme can be a novel strategy to prevent the progression of inflammatory diseases and lung cancer. Here, we report the biophysical and biochemical characterization of the HCD. Our analytical ultracentrifugation (AUC) results showed that HCD is a monomer in solution. Among the various acetylated carbohydrates, N-acetyl-D-galactosamine was found to be the most potent substrate candidate using fluorescence-based enzyme activity assay. Next, based on the induced coupled plasma mass spectroscopy (ICP-MS) results and enzyme assay, manganese ion is most active metal cofactor of HCD. We also found that the Asp13 of HCD was directly involved in deacetylase activity. Our results provide insight into its biological characteristics in cellular signaling pathway as well as pathological progress such as inflammatory diseases and cancer. We also performed HTS inhibitor screening of the enzyme using 1,922 compounds of FDA-approved library and 4 hits were selected as the deacetylase inhibitors. This research might open a breakthrough to application of this protein as a potential biomolecule for drug target in cancer treatment.

P853/B874

An Omics-based Study of the Role of C3dg in Keratinocytes: Rnasequencing, Antibody-chip Array, and Bioinformatics Approaches.

J. Lee; Sungkyunkwan Univ., Suwon, KOREA, REPUBLIC OF.

Previously, we have identified the C3dg protein as an important player in the pathogenesis of atopic dermatitis (AD). In this study, we aimed to identify critical factors associated with C3dg in human keratinocytes based onhigh-throughput screening (HTS) approaches.We overexpressed C3dg in HaCaT

human keratinocytes and conducted serial HTS studies, including RNA sequencing analysis integrated with antibody-chip arrays and implementationof bioinformatics algorithms (PPI mappings). Cumulatively, these approaches identified several novel C3dg-associated genes and proteins that are thought to be significantly involved in skin diseases including AD. These novel genes and proteins included LPA, PROZ, BLK, CLDN11, and FGF22, which are believed to play important roles in C3dg-associated skin functions in keratinocytes, as well as genes related to the two importantpathways of systemic lupus erythematosus and Staphylococcus aureus infection. In particular, FGF22 is a unique gene that was detected and validated in all methods applied in this study. By integrating the datasets obtained from these HTS studies and utilizing the strengths of each method, we obtained new insights into the functional role of C3dg in keratinocytes. The approach used here contributes to clinical understanding of C3dg-associated applications and may also be applicable to treatment of AD.

***Daf-16* Plays a Critical Role in Metformin Mediated Anti-aging Effects in *C. Elegans*.**

A. Chen[1], M. Cao[2]; [1]Massachusetts Academy of Math and Science, Worcester, MA, [2]Clemson University, Clemson, SC.

The biguanide compound metformin is the first-line treatment for people with type 2 diabetes and one of the most widely prescribed drugs in the world. Besides its anti-diabetic properties, metformin has pleiotropic effects in a variety of cellular processes and pathological conditions. Most prominently, a growing body of evidence in model organisms supports the role of metformin in delaying aging and improving health span, and several large randomized clinical trials are currently ongoing to evaluate the protective effects of metformin in aging and age-related diseases. Despite extensive research in recent years, the exact mechanisms underlying the anti-aging effects of metformin remain elusive. To further elucidate the molecular pathways on which metformin acts to achieve its pro-longevity effects, a genetic screen was performed in the model organism *C. elegans* using strains carrying loss-of-function mutations in key genes of several conserved longevity pathways. Supplementation of metformin hydrochloride (100 mM) increased the mean lifespan for *akt-1(-/-)* from 15.33 to 20.12 days (p<1.0e-6), for *jnk-1(-/-)* from 15.51 to 18.77 days (p=4.4e-5), and for *hsf-1(-/-)* from 10.50 to 11.79 days (p=7.3e-6), indicating that these genetic pathways are not required for metformin mediated lifespan extension. By contrast, no significant difference in mean lifespan was observed for *daf-16(-/-)*, indicating that the anti-aging effects of metformin are in part modulated by *daf-16*. Surprisingly, a profound decrease in lifespan induced by metformin supplementation was observed for *age-1(-/-)* (from 38.54 to 22.74 days, p<1.0e-6) and *daf-2(-/-)* (from 40.63 to 21.54 days, p<1.0e-6), suggesting that metformin may bypass the function of *daf-2* and *age-1* to modulate the activity of *daf-16*. The metformin mediated lifespan reduction in *age-1(-/-)* and *daf-2(-/-)* was reproduced in an independent study and found to be dose-dependent (0-100 mM). Taken together, our genetic analysis not only reveals that metformin prolongs *C. elegans* lifespan in a *daf-16*-dependent manner, but also suggests a novel signaling pathway modulating *daf-16*. Further investigations involving transcriptome analysis are currently underway to understand the underlying mechanisms.

Adipocytes and Metabolism

Study of Anti-obesity Effect of Purple Corn Cobs Extracts in 3t3-l1 Preadipocytes Cells.

G. Nam, H. Kawk, Y. Park, K. Jo, S. Kim, Y. Kim; Hannam University, Daejeon, KOREA, REPUBLIC OF.

Purple corn cobs is known for its anti-inflammatory and anti-microbial effects. In this study, we determined the effects of ethanol extract of Purple corn cobs on anti-obesity activities in 3T3-L1 preadipocytes. In *vitro* experiments to prevent obesity and improve anti-obesity effects, research using 3T3-L1 preadipocytes is essential, it also distinctly represents morphologic and molecular changes. Our results showed that Purple corn cobs extract decreased the differentiation of 3T3-L1 preadipocytesusing oil red O staining through decreasing the lipid droplet and had no cytotoxicity in 3T3-L1 preadipocytes using WST-1 assay (100 μg/ml and 200 μg/ml). Also, the concentrations of triglycerides(TG) were gradually reduced in 3T3-L1 preadipocytes cells with Purple corn cobs extract (N: 100%, 100 μg/ml: 64.5%, 200 μg/ml: 38.1%) using ELISA assay. An d Purple corn cobs extract suppressed the Expression of PPARγ, C/EBPα and Acetyl-CoA Carboxylase (ACC) in a dose-dependent manner by Western blot analysis. Taken together, our results demonstrate that Purple corn cobs extract indicates anti-obesity effects in *vitro* situation and has potential uses in chemotherapeutic drugs.

P856/B877

Profiling of MiRna Expression in Exosomes Secreted from Differentiating Adipocytes.

K. Ojima[1], S. Muroya[1], H. Wada[2], K. Ogawa[2], M. Oe[1], K. Takimoto[2], T. Nishimura[3]; [1]Institute of Livestock and Grassland Science, NARO, Tsukuba, JAPAN, [2]Nagaoka University of Technology, Nagaoka, JAPAN, [3]Hokkaido University, Sapporo, JAPAN.

Exosomes, tiny vesicles with 30-100 nm diameters, are released from a variety of cells to communicate with recipient cells. Exosomes contain microRNAs (miRNAs) which suppress translational level(s) of target gene(s). Our previous proteomic study demonstrated that cultured adipocytes secrete not only classical growth factors but also exosomes during adipocyte differentiation (*FEBS Open Biol*. 2016 6: 816-26). However, it remains unclear what type of miRNA is contained in adipocyte secreted exosomes. To address this, we overviewed the differentially expressed miRNAs in adipocyte secreted exosomes during adipocyte differentiation. First, exosome fractions were isolated from cultured media of 3T3-L1 cells following adipocyte differentiation. We found that differentiating adipocytes secreted distinct amounts of exosomes during adipocyte differentiation. The largest amount of exosome was released just before adipocyte differentiation (DM0). The second peak was observed at day 4 following differentiation (DM4). Next, to investigate the expression levels of exosome-derived miRNA, microarray analysis was conducted. The numbers of detected miRNA were 329, 426 and 406 at DM0, DM4, and DM12, respectively. Approximately 10 % of identified miRNAs showed more than 2-fold increment (DM12/DM0) with significant differences. Well-known adipocyte-associated miRNAs such as miR-107-3p and miR-103-3p were contained in this category. By contrast, approximately 8% of miRNAs were altered with less than 0.5-fold of DM12/DM0. Expression levels of representative miRNAs were verified by quantitative PCR. Furthermore, gene ontology (GO) analysis using >2-fold-changed exosome-derived miRNAs predicted target genes which were involved in regulation of transcription, cell proliferation, etc. Collectively, our data showed that differentiating 3T3-L1 cells released exosomes which contained different types and amounts of miRNAs.

P857/B878

Analysis of Fgf Signaling in Sebocytes and Adipocytes.

Y. Fujimoto, 22, N. Doi, 21, T. Imamura, 63; Tokyo University of Technology, Tokyo, JAPAN.

[Objectives] Sebaceous gland cells (sebocytes) and adipocytes synthesize and store a large amount of lipid in vivo that serve for the functional maintenance of the skin surface and for energy storage/mechanical cushion, respectively. Recently, fibroblast growth factor (FGF) receptor (FGFR) signaling has been reported to be involved in the regulation of lipid synthesis in these cells. Acne formation has been attributed to enhanced FGFR2 downstream signals. FGF2 and FGF10 were reported to regulate adipocyte differentiation and proliferation. In this study, we aimed at clarifying the involvement of FGF signaling in the regulation of lipid synthesis, proliferation and differentiation of sebocytes and adipocytes. [Methods] an immortal SZ95 human sebocytes established from facial sebaceous glands and 3T3-L1 mouse preadipocytes were used. Differentiation was induced by LA in SZ95 cells, or by insulin, IBMX, and dexamethasone in 3T3-L1 cells. The lipid droplets synthesized and accumulated by these cells were stained with either Oil Red O or with Nile Red, and the lipid staining pattern was analyzed microscopically or by flow cytometry. Expression levels of lipid-synthesis related enzymes, FGF ligands, and growth- and differentiation-related genes were determined in the cells treated with fatty acids, FGF ligands, FGFR inhibitors or other compounds. [Results] in SZ95 cells, treatment with linoleic acid (LA) remarkably enhanced lipid synthesis. This lipid synthesis was upregulated by FGF18, and was suppressed by FGF7. In differentiation-inducing culture of 3T3-L1 cells, FGFC (a universal ligand for all FGFR subtypes) or FGF18 abrogated cellular differentiation. Proliferation of both SZ95 cells and undifferentiated 3T3-L1 cells was enhanced by FGF7 and FGF10, but was suppressed by FGF18. LA treatment of SZ95 cells resulted in increased FGF18 expression and decreased FGF7 expression. [Conclusions and Discussion] While proliferation of sebocytes and preadipocytes are similarly enhanced by FGFR2b ligands FGF7 and FGF10, lipid biosynthesis/ adipocyte differentiation is differentially regulated by FGFs with different FGFR specificities. The increased FGF18 gene expression and decreased FGF7 gene expression in LA-treated SZ95 cells suggest that proliferation, differentiation and lipid biosynthesis are inseparably regulated involving FGF signaling pathways.

P858/B879

STIM2β Regulates White Adipose Tissue (WAT) Development.

S. Jeong, 49919, C. Park; UNIST, Ulsan, KOREA, DEMOCRATIC PEOPLE'S REPUBLIC OF.

Adipose tissue has a specialized role in energy storage and thermogenesis. However, when there is excess lipids over the storage capacity of adipose tissue, excess lipids “spill over” may occur from adipose to non-adipose tissues. Abnormal lipid accumulation in non-adipose tissues such as skeletal muscle and liver, not in WAT, is known to cause lipotoxicity : endoplasmic reticulum stress, increased inflammation response, mitochondrial dysfunction, insulin resistance (IR) and other effects. Therefore, profer regulation of adipogenesis is important for the homeostasis of lipid metabolism. There was several studies that relates SOCE and adipogenesis. However, the detailed mechanism of SOCE on the regulation of adipogenesis remains elusive. In this study, we show STIM2β expression level is increased during adipogenesis and functions as a regulator of adipogenesis. STIM2β KO 3T3-L1 cell line showed increased lipid accumulation during adipogenesis in comparison with WT cell line. STIM2β KO affects to Ca^{2+} signaling on 3T3-L1 cell and leads change in cell cycle. STIM2β KO mouse showed difference in

adipose tissue development in comparison with WT. Our data provide an insight on the importance of intracellular Ca^{2+} concentration regulation by STIM2β on adipose tissue development.

P859/B880

Adipocyte-macrophage Crosstalk Upon the Expression of Catecholamine Synthesis Pathway Genes.

A. Gomes[1,2], **F. Leite**[3,4], L. Ribeiro[2,5]; [1]Department of Biomedicine, Unit of Biochemistry, Faculty of Medicine, University of Porto, Porto, PORTUGAL, [2]I3S-Instituto de Investigação e Inovação em Saúde, University of Porto, Porto, PORTUGAL, [3]Centro Hospitalar Do Porto, EPE, Porto, PORTUGAL, [4]UMIB/ICBAS - Unit for Multidisciplinary Investigation in Biomedicine- Instituto de Ciências Biomédicas Abel Salazar, University of Porto, Porto, PORTUGAL, [5]Department of Public Health Sciences, Forensic and Medical Education, Faculty of Medicine, University of Porto,, Porto, PORTUGAL.

The crosstalk between adipocytes and macrophages contributes to the systemic metaflammation observed in obesity and associated immunometabolic disease clusters. While adipocytes and macrophages produce, secrete and respond to catecholamines (CA), the underlying mechanisms regulating their synthesis in the interplay between immune and metabolic systems remain unknown. Tyrosine hydroxylase (TH) and phenylethanolamine N methyltransferase (PNMT) are two of the main enzymes responsible for CA synthesis. We hypothesize that under an obesogenic state CA play a role in the crosstalk between metabolic and immune systems. A model of indirect cell coculture with conditioned medium (CM) from RAW 264.7 macrophages (with or without LPS-activation) and 3T3-L1 adipocytes and preadipocytes was created to study the effect of cellular secretomes on CA synthesis pathway. The relative expression (mRNA levels) of TH and PMNT involved in CA synthesis was determined by qRT-PCR. RAW 264.7 macrophages, both LPS-activated and non-LPS-activated, were exposed to CM from preadipocytes and mature adipocytes. These cells were exposed to LPS, interleukin 4 and interferon γ. We also assessed the effect of 3T3-L1 preadipocytes and fully differentiated adipocytes secretomes upon the expression of TH and PNMT in both LPS-activated and nonactivated RAW 264.7 macrophages. We found a decrease of TH and PNMT expression during the adipocyte differentiation process. The secretome from LPS-activated macrophages downregulated TH and PNMT expression in preadipocytes, but not in mature adipocytes. Mature adipocytes CM induced a decrease of PNMT levels in RAW 264.7 macrophages. Pre and mature adipocytes showed a similar pattern of TH, PNMT and peroxisome proliferator-activated receptor gamma expression after exposure to pro and anti-inflammatory cytokines. We evidenced macrophages and adipocytes coregulate the expression of CA synthesis enzymes through their secretome, with a putative role for non-inflammatory signaling pathways. Mediators released by macrophages seem to equally affect CA production by adipocytes, while adipocytes secretome preferentially affect adrenaline production in macrophages. CA synthesis regulation seems to be more determinant in early stages of adipogenic differentiation. The discovery that macrophages and adipocytes co-regulate CA synthesis suggest these amines are key signaling molecules connecting immune and metabolic systems regulating immunometabolic disease clusters.

P860/B881

Changes in Gene Expression of Lipid Metabolism Genes in Collaborative Cross Model of Non-alcoholic Fatty Liver Disease.

R. A. Willett, V. Tryndyak, A. De Conti, A. Watson, B. Borowa-Mazgaj, I. Pogribny; National Center for Toxicological Research (NCTR/FDA), Jefferson, AR.

Non-alcoholic fatty liver disease (NAFLD) is the most common form of liver disease in the Western world, affecting approximately 30% of the general Western population with strong onset prevalence with metabolic syndrome, obesity, and diabetes. NAFLD, characterized as the accumulation of fat in the liver in the absence of excessive alcohol drinking and secondary liver pathologies, can worsen and progress to non-alcoholic steatohepatitis (NASH) or severe pathologies such as fibrosis and cirrhosis resulting in irreversible liver damage. Currently, the molecular mechanism of NAFLD onset and progression is unknown, likely due to the great genetic diversity of NAFLD patients, urging the discovery of genetic markers that could be non-invasively analyzed in patients. In this study, to mimic the heterogenous population of individuals affected by NAFLD, we utilized the collaborative cross (CC) mouse population, a state-of-the-art model that mimics the genetic diversity of the human population with the added benefit of reproducible genetic backgrounds. Male and female CC mice were fed a high fat/high sugar (HF/HS) diet for 12 weeks and then analyzed for NAFLD prevalence and progression. Similar to human patients, we observed significant diversity between individual mouse strains body weight gain, liver lipid metabolism disturbances characterized by elevated triglyceride (TG) and total cholesterol content, as well as histopathological indicators of NAFLD-associated liver injury. Furthermore, gene expression analysis of lipid metabolism genes revealed not only significant changes in the population wide expression, but also interindividual strain differences in several marked genes regulating lipid accumulation, including *Cd36*, *Fabp2*, and *Ppar-ɣ*. Furthermore, we found that altered gene expression of lipid accumulation regulation genes correlated with the accumulation of liver TG. In conclusion, our model of NAFLD mimics the genetic heterogeneity observed in the human population of NAFLD patients in terms of onset, and severity/progression of the disease. This indicates a great value of the CC mouse model as a strong tool for the identification of non-invasive biomarkers of NAFLD and key molecular pathways that correlate with disease onset and progression.

P861/B882

Prokineticins in Liver Diseases- New Insights of Iron Trafficking Proteins and Dysregulation of Nitric Oxide Behavior in Patients with Non-alcoholic Fatty Liver Disease.

S. PRAKASH[1], P. PRIYATMA[2], S. SHALIMAR[3], N. K. VIKRAM[4]; [1]Department of Laboratory Medicine, ALL INDIA INSTITUTE OF MEDICAL SCIENCES, ANSARI NAGAR, NEW DELHI, INDIA-110029, New Delhi, INDIA, [2]Department of Laboratory Medicine, ALL INDIA INSTITUTE OF MEDICAL SCIENCES, ANSARI NAGAR, NEW DELHI, INDIA-110029, NEW DELHI, INDIA, [3]Department of Gastroenterology, ALL INDIA INSTITUTE OF MEDICAL SCIENCES, ANSARI NAGAR, NEW DELHI, INDIA-110029, New Delhi, INDIA, [4]Department of Medicine, ALL INDIA INSTITUTE OF MEDICAL SCIENCES, ANSARI NAGAR, NEW DELHI, INDIA-110029, New Delhi, INDIA.

Prokineticins in liver diseases: new insight of iron trafficking proteins and dysregulation of nitric oxide behavior in patients with non-alcoholic fatty liver disease NAFLD is increasing worldwide, imitating current epidemics of lifestyle diseases. This is escorted by Prokineticins in conjunction with nitric oxide interlinked pathways either vasodilatory effect of NO gene transcription or iron metabolic abnormalities

leading to NAFLD/NASH. Iron trafficking proteins growth differentiation factor-15 and Prokineticins as mediators of inflammatory molecules may have potential role in NAFLD, thus we explored whether GDF-15, iron trafficking proteins and Prokineticins are involved in severity of NAFLD. Blood and biopsy samples were collected from the Gastroenterology, AIIMS, Delhi. Each was screened for serology and categorized into sub-groups, i.e. NAFLD (n=30), Hepatitis (disease control n=38), diabetes mellitus without metabolic syndrome (DM without Mets) (n=20), Metabolic syndrome without diabetes mellitus (Mets without DM) (n=25), and Healthy subjects (n=25). Adiponectin, leptin, Insulin Resistance, BMI, pro-inflammatory and anti-inflammatory cytokine, iron trafficking proteins, Prokineticins and GDF-15 levels were measured in all groups. GDF15 levels, iron trafficking proteins and Prokineticin expressions were higher in NAFLD, DM with MetS, and MetS without DM than in healthy controls. GDF-15 levels may have hidden relations in respect to body weight, waist hip ratio, BMI and HOMA IR. Prokineticins expressions were higher in NAFLD, HCC patients, and DM with Metabolic syndrome than diseases controls (HBV & HCV) and healthy controls. Expressions of Prokineticin-1 have noticed 3-4 fold change in patients with cirrhosis and liver cancer (HCC). Furthermore, increasing pattern of viral load of HBV and HCV infections ($>10^4$ IU/ml) have suggested that the expression of Prokineticins were 3-4 fold in patients with cirrhosis and liver cancer (HCC). Our finding suggests that high circulating levels of GDF-15, iNOS and overexpression of Prokineticins could be potential biomarker of NAFLD, and suppressed levels of antioxidants gene could be linked in development of future diabetes, CVD and metabolic syndrome. Thus, Prokineticins and dysregulation of iron trafficking proteins and NOS expressions could be novel emerging biomarkers to treat NAFLD.

P862/B883

Rapid Induction of Skeletal Muscle Thermogenesis in the Absence of Interscapular Brown Adipose Tissue.

E. Gorrell, C. M. Novak; Kent State University, Kent, OH.

Obesity is a disorder caused by positive energy balance, where energy intake is greater than energy output, leading to weight gain. One strategy to counter energy imbalance is to increase output, or energy expenditure (EE). Skeletal muscle makes up 40% of the body composition of non-obese adults and is a large contributor to BMR, which accounts for 50-70% of total daily EE. Thus, skeletal muscle is a promising potential therapeutic target for increasing EE passively to promote weight loss. However, this potential of skeletal muscle has been historically less studied as a component to obesity therapy than adipose, especially brown adipose tissue (BAT). We have discovered a neuronal pathway that contributes to a physiological increase in energy expenditure by non-shivering thermogenesis in skeletal muscle when rats are exposed to a predator odor (PO) from ferrets. We predict that PO-induced skeletal muscle thermogenesis can occur independently of BAT. Male (n=8) and female (n=8) Sprague-Dawley rats underwent surgical excision of interscapular BAT (n=4/sex) or sham surgery (n=4/sex), and transponders were implanted in the left and right gastrocnemius muscles. Single-housed rats were habituated to experimental conditions prior to PO and control exposure. PO and control towels (1.5”x2”) were placed in home cages, and PO-induced thermogenesis was measured for 120 minutes after exposure. Activity thermogenesis following PO exposure was measured using a treadmill walking protocol, and calorimetry was used to measure differences in EE. PO exposure induced skeletal muscle thermogenesis similarly in animals with and without interscapular BAT, and there was no significant difference in activity thermogenesis. Similarly, PO exposure did not significantly affect the PO-associated increase in EE. The excision of interscapular BAT, the largest depot in rats, did not impede PO-induced

skeletal muscle thermogenesis or EE. These results do not support the idea that BAT makes a meaningful contribution to PO-induced thermogenesis or EE and implicate skeletal muscle as a potential target for reducing positive energy balance that contributes to obesity.

P863/B884

Impaired Branched-chain Amino Acids Catabolism in White Adipose Tissue of Non-obese an kyrin-b Mutant Mice Contributes to Systemic Metabolic Dysfunction.

J. Tzeng, A. M. Aguillard, **D. Lorenzo, 27515**; University of North Carolina at Chapel Hill, Chapel Hill, NC.

Increased serum levels of branched-chain amino acids (BCAA) in obese humans are one of the most accurate predictors of both risk for developing insulin resistance (IR) and metabolic outcomes of weight loss interventions. However, whether elevated circulating BCAA levels are causative of obesity and metabolic impairment or a response to it is not clear. Likewise, the mechanisms underlying the relationship between elevated BCAA levels and impaired peripheral insulin response remains to be fully elucidated. Young knock-in mice bearing the human type 2 diabetes (T2D)-linked R1788W variant in the cytoskeletal protein ankyrin-B (AnkB) show normal body weight and composition. In addition, these mice exhibit increased glucose uptake by white adipose tissue (WAT) due to deficits in the internalization of the glucose transporter GLUT4. We previously reported that sustained elevations in glucose disposal in WAT lead to the onset of increased adiposity, lipotoxicity, systemic inflammation, and IR in an kB mutant mice with age or in young animals fed Western diets. Transcriptomic analysis of non-obese R1788W an kB mice identified gene transcriptional changes consistent with lower BCAA catabolism in WAT. Here, we show that an kB deficiency impairs BCAA catabolism in WAT prior to the onset of obesity. Lean R1788W an kB mice show downregulation of BCAA catabolic enzymes in WAT, concomitant with elevations in serum BCAA and related acylcarnitines detected by targeted metabolomics. In contrast, an kB deficiency did not alter BCAA oxidation in skeletal muscle. Results from studies in which control and R1788W an kB mice were fed isocaloric low fat (LFD) and high fat (HFD) diets, or similar diets enriched in BCAA, suggest that increases in circulating BCAA levels cause accumulation of catabolic intermediates in skeletal muscle that trigger mitochondrial dysfunction and impair insulin signaling. Similarly, elevated BCAA altered the secretory capacity of pancreatic beta cells and caused endoplasmic reticulum stress. Our data indicates that elevated circulating BCAA impair glucose tolerance and insulin sensitivity independently of obesity, and that these deleterious effects are potentiated by a HFD.

P864/B885

Voluntary Exercise Training Improves Body Weight of Leptin-Deficient ob/ob Mice by Changes in Hepatic Stearoyl-CoA Desaturase 1 and Deleted-in-Breast-Cancer 1 Protein Levels.

W. Lim[1], C. Kang[2]; [1]Cheongju University, Cheongju, KOREA, REPUBLIC OF, [2]Inha University, Incheon, KOREA, REPUBLIC OF.

Deleted-in-Breast-Cancer-1 (Dbc1) ablation causes obesity and stearoyl-CoA desaturase 1 (SCD1) induces the biosynthesis of monounsaturated fatty acids. The purpose of this study was to determine whether voluntary wheel running (VWR) alters SCD-1 and Dbc1 protein levels in the liver of leptin-deficient ob/ob mice. Twenty-five Ob/Ob mice were divided into 2 groups (ob/ob-Sed, ob/ob-Ex). After 10 weeks, VWR significantly reduced body weight without affecting fatty acid synthase and CD36 protein levels. The improvement is associated with changes in hepatic SCD1 and Dbc1. We found that

hepatic SCD-1 protein levels were significantly increased and Dbc1 protein levels were decreased in ob/ob-Sed animals; however, the effect was attenuated by VWR. This is the first study showing that VWR has strong effects on hepatic SCD1 and Dbc1 of ob/ob mice and provide key insight concerning the effect of exercise on obesity.

The New Role of Msc1 in Adipogenesis and Its Relationship to Fas.

H. Lee[1,2], G. Kong[1,2], Q. Tran[1,2], C. Kim[1,2], J. Park[1,2]; [1]Department of Pharmacology, Metabolic Syndrome and Cell Signaling Laboratory, Institute for Cancer Research, College of Medicine, Chungnam National University,, Daejeon, KOREA, REPUBLIC OF, [2]Department of Medical Science, College of Medicine, Chungnam National University, Daejeon, KOREA, REPUBLIC OF.

Background and aims: Adipocytes play a role in energy homeostasis and process the largest energy reserve as triglycerol stay in a dynamic state, they start expanding when the energy intake is higher than the expenditure and undergo mobilization. Adipogenesis is a tightly regulated cellular differentiation process, in which the preadipocytes are transformed into differentiated adipocyte cells. Recent evidence indicates that adipose tissue is an active endocrine organ which helps to regulate several body functions, including insulin-mediated processes, lipid and glucose metabolism. In addition, adipose tissue plays a role in coagulation and some aspects of inflammation. Previous studies found that there are loss of body weight and fat storage in Metabolic Syndrome complex (MSC1) knockout mice. Based on this evidence, we hypothesized that MSC1 would affect adipogenesis and lipogenesis. **Materials and methods:** in this study, we used 3T3L1 cells, a mouse adipocyte, using western blotting and qRT-PCR to confirm the expression level of adipogenesis, lipogenesis genes and MSC1 expression. Promoter assay have used to identify genes regulated by MSC1. An d, the animal model used MSC1 transgenic mice, and we compared the metabolic changes with Wild type mice on fed high fat diet. **Results:** in our study, MSC1 is upregulated during adipogenic differentiation at an early stage. Also mRNA levels of MSC1 and Fatty acid synthase (FAS) are increased during the same period of adipogenic differentiation. On the third day of differentiation, MSC1 overexpression increased FAS expression together with the acceleration of PPARγ and FABP4 expression. On the contrary, shRNA-mediated depletion of MSC1 resulted in the reduction of FAS, PPARγ and FABP4 expression. In addition, MSC1 is able to directly bind to FAS promoter in 3T3L1 cells. Histological analysis of the adipose tissue revealed hypertrophy in HFD-fed MSC1 transgenic mice, indicating that MSC1 overexpression affects the adipogenesis and obesity. **Conclusion:** Taken together, MSC1 is an important modulator of adipogenesis and lipogenesis. Furthermore, these results suggest that the decreased MSC1 expression that occurs an important role in preventing lipid accumulation and obesity.

P866/B887

A Role for Alms1 (Alström Syndrome 1) in Leptin Release from Adipocytes.

V. C. Ortiz[1,2], T. Liao[2], M. Mendez[2], P. A. Ortiz[2], E. Mottillo[2]; [1]University Liggett Schools, Grosse Pointe Farms, MI, [2]Henry Ford Hospital, Detroit, MI.

Inactivating mutations in the ALMS1 gene in humans cause early onset obesity and metabolic syndrome. Deletion of ALMS1 in rodents induces early onset obesity and insulin resistance on normal chow. The mechanisms by which ALMS1 cause obesity are not clear but likely involve the development of leptin resistance since adult ALMS1 Knock out (KO) rats are hyperphagic and hyperleptinemic. However, it is

not clear whether ALMS1 is involved in leptin release and expression in adipocytes prior to development of obesity. ALMS1 has been associated to ciliary function which may play a role in adipogenesis. We hypothesized that deletion of ALMS1 would increase leptin release from fat pads of young ALMS1 KO rats, which should contribute to hyperleptinemia. To study this, we obtained abdominal fat pads from young ALMS1 KO rats (8 weeks) prior to changes in body weight. We found that leptin release (normalized to fat weight) was 120% higher (from 30±8 to 56± 15 pg/mg tissue/2h) in abdominal fat pads from ALMS1 KO rats. Plasma leptin levels were dramatically higher in young ALMS1 KO rats (ALMS1: 3530±300 vs. WT: 172±16 pg/ml, $p<0.05$) despite no significant differences in body weight or baseline glucose. To study the mechanisms behind higher leptin release we performed RNAseq in freshly isolated abdominal fat pads. 12,860 genes were identified and quantified. In fat pads from ALMS1 KO there were 163 upregulated and 237 significantly downregulated genes. Leptin mRNA was significantly increased (1.68 Log2 fold, $p<0.0001$, n=4) as were several genes involved in lipogenesis (Elovl6, Scd1, Scd2, Mogat2, Acly, Lpl, Dgat2, Fasn). Interestingly, at least 10 ciliary genes were downregulated (Traf3ip1, Pard6g, Cngb1, Ak7, Ttll1, Mlf1, Ccdc162, Dnah6, Ccdc187, Foxj1) suggesting a role for ALMS1 in ciliary function. To examine this, we immunolabeled cilia in abdominal adipocytes with gamma acetylated tubulin antibodies, and examined sections by confocal microscopy. Short cilia (1-2 μm) were observed in both WT and ALMS1 KO adipocytes. We conclude that ALMS1 is likely involved in leptin release from adipocytes. It is not clear whether increased leptin expression and release is secondary to neuroendocrine alterations or alterations in cilia-induced signaling in adipocytes. Our data also point to an important role for ALMS1 in regulating adipocyte function.

P867/B888

Homeodomain-interacting Protein Kinase 2 (hipk2) Regulates Ucp1 Expression in Brown Adipocyte through Modulating Pka Signaling and Ppar Activation.

E. Koh; Yonsei University, Seoul, KOREA, REPUBLIC OF.

Homeodomain-interacting protein kinase 2 (HIPK2) is a serine/threonine kinase that influences multiple cellular functions including apoptosis and differentiation through modulation of transcriptional regulators and signaling molecules. Recently, it is reported that HIPK2 is required for white adipocyte differentiation and development. However, the role of HIPK2 in brown adipocytes has not been reported even through HIPK2 expression is enriched brown adipose tissues (BAT). We observed that HIPK2 expression is significantly induced during the differentiation of mouse brown adipocyte cell line (iBPA) in accordance with uncoupling protein1 (UCP1). To assess the role of HIPK2 in brown adipocyte, we generated *HIPK2* knockout (K/O) cells by knocking-in EGFP reporter gene into HIPK2 genome via CRISPR/Cas9-induced homology-independent DNA repair. HIPK2 K/O cells showed dramatic decrease of UCP1 expression whereas expression levels of ACLY, Adrb3, PPAR-α, PPAR-$_{\gamma}$, FASN, Srebf1, ACACA and MOGAT are slightly decreased or increased compared to control cells. Furthermore, we observed that UCP1 induction in response to CL316243, an agonist of β3 adrenergic receptor, is decreased in HIPK2 knockout iBPA cells (D5) and defects of HIPK2 exhibit decreased level of phosphorylated CREB and p38 which is involved in the regulation of UCP1 gene expression under the treatment of CL316243. In addition, HIPK2 increased PPAR$_{\gamma}$-mediated PPRE-tk-luciferase activity. These results suggest that HIPK2 is closely involved in modulating signaling events regarding UCP1 expression. This work was supported by a National Research Foundation of Korea (NRF) Grant funded by the Korean Government (MSIP) (NRF-2017R1A2B4009674, NRF-2017R1A2B4007462 and NRF-2011-0030086)

P868/B889

Ginsenoside Rd Inhibits Lipid Accumulation by Downregulating Adipogenesis and Lipolysis in 3T3-L1 Preadipocytes.

M. Yeom, Y. Kim, D. Hahm; Kyung Hee University, Seoul, KOREA, REPUBLIC OF.

Obesity, a state of excess fat accumulation in adipocytes, is a growing public health issue in the developed world. Given that ginsenoside Rd, one of major ginsenosides in ginseng (the root of *Panax ginseng* C.A. Meyer) possesses anti-inflammatory and antioxidant activities, it may have potential anti-adipogenic effect. In this study, we investigated whether Rd inhibits adipogenesis and lipid accumulation in 3T3-L1 preadipocytes. 3T3-L1 preadipocytes were induced to differentiate into adipocytes in the presence or absence of Rd for 8 days. Rd suppressed the differentiation and inhibited lipid accumulation as indicated by lower intracellular lipid and triglyceride contents as well as reduced adipogenic gene expression upon treatment. Rd-treated 3T3-L1 cells released more glycerol, indicating increased lipolysis, which was supported by increased expression of lipolysis-related genes, including adipose triglyceride lipase. In conclusion, Rd markedly decreased intracellular lipid accumulation by downregulating adipogenic gene expression and enhanced lipolysis, implying it may have potential as an anti-obesity agent.

***Hydrangea Serrata* (thunb.) Ser. Extract Prevents Hyperlipidemia and Obesity Via Lipid Metabolism Modulation in High Fat Diet-induced Obese Mice.**

H. Han[1,2], D. Myung[1,2], K. Chung[1], Y. Shin[3], S. Lee[3], K. Lee[1,2]; [1]Department of Pharmaceutical Biochemistry, College of Pharmacy, Kyung Hee University, Seoul, KOREA, REPUBLIC OF, [2]Department of Life and Nanopharmaceutical Science, Graduate School, Kyung Hee University, Seoul, KOREA, REPUBLIC OF, [3]Department of New Material Development, COSMAXBIO, Seongnam, KOREA, REPUBLIC OF.

Recently, there has been a growing propagation of obesity caused by global tendency towards reduction of physical activity and an augmented dietary intake of fats, sugars, and high calories. Obesity is a major risk factor of diabetes, cardiovascular diseases, metabolic diseases, and several forms of cancer, such as breast, colon, and prostate. The aim of this study was to examine the anti-obesity effect of hot water extract of *Hydrangea serrata* (Thunb.) Ser. (WHS). To investigate the pharmacological activities of WHS in *vivo*, we examined several obesity-related parameters in high fat diet (HFD)-induced obese mice. Compared to the HFD group, oral administration of WHS showed significant reduction of body weight gain (24.21%, 24.46%, and 31.01% at 75, 150, and 300 mg/kg). The fat-pad weight and the percentage of fat in tissue measured by dual X-ray analyzer were also notably decreased by WHS administration. The expanded size of adipocyte in HFD group were markedly decreased in WHS-administered group. WHS intake also effectively ameliorate the increased serum levels of total cholesterol, low-density lipoprotein (LDL), leptin, and insulin. Moreover, fat accumulation in the liver were distinctly improved by WHS administration. All these results strongly suggest that dietary supplementation of WHS could be helpful in preventing or treating obesity. This work was supported by "Food Functionality Evaluation program" under the Ministry of Agriculture, Food and Rural Affairs and partly Korea Food Research Institute (2019G0190300-01).

P870/B891

Elucidating the Role of TM6SF2 in Nonalcoholic Fatty Liver Disease.

M. To, M. Roberts, M. Kober, J. Olzmann; University of California, Berkeley, Berkeley, CA.

Nonalcoholic fatty liver disease (NAFLD) is the most common form of liver disease, affecting an estimated 80-100 million Americans. NAFLD is characterized by accumulation of excess fat stored in the liver, which can lead to nonalcoholic steatohepatitis, followed by cirrhosis. Previous exome-wide association studies found an E167K mutation of TM6SF2 is associated with susceptibility to NAFLD. Emerging data show that TM6SF2 promotes secretion of lipidated lipoproteins, preventing the accumulation of triacylglycerols (TAGs) in hepatocytes. However, the precise mechanism by which this occurs is yet to be determined. Structural predictions of TM6SF2 report 7-10 transmembrane domains, with 2 of 6 TOPCONS models placing the C-terminus of TM6SF2 in the cytoplasm. To map the topology of TM6SF2, we performed fluorescence microscopy of cells expressing N- and C-terminally tagged TM6SF2 under conditions in which luminal epitopes were protected. Our results show that the N-terminus of TM6SF2 is in the cytosol, whereas the C-terminus resides in the lumen. Based on both our data and structural predictions, the E167K mutation of TM6SF2 should reside in the lumen. However, further mapping of the transmembrane domains is necessary. To understand the cellular function of TM6SF2, we performed proteomic profiling of tagged TM6SF2 in human hepatoma cells to identify interaction partners. Our proteomics revealed that ApoB100, a key protein in the secretion of VLDLs, interacts with TM6SF2. Whether this interaction is important for lipidation of VLDLs, and whether the E167K mutation affects this process is yet to be determined. Understanding the structure of TM6SF2 and its relationship with its binding partners will provide a more comprehensive understanding of the causes and potential treatments of NAFLD.

Muscle Structure, Function, and Disease

New Players in the Pathogenesis of a Lysosomal Storage Disease.

N. Meena, N. Raben, R. Puertollano; Cell and Developmental Biology Center, National Heart, Lung and Blood Institute, National Institutes of Health, Bethesda, MD.

There is growing evidence that the pathogenesis of tissue damage in a large group of lysosomal storage diseases (LSDs) cannot be adequately explained by the enlargement of lysosomes filled with undigested materials. This concept fully applies to Pompe disease, a deadly neuromuscular disorder caused by the absence or deficiency of glycogen-degrading lysosomal enzyme acid alpha-glucosidase (GAA). In both the most severe infantile form of the disease and in its so called milder later-onset form, skeletal muscle is a major affected tissue. By using biochemical and molecular analyses, as well as confocal microscopy of live or fixed muscle fibers from our mouse model of the disease, we have shown that the lysosomal entrapment of glycogen initiates a pathological cascade including altered autophagy, mitochondria abnormalities, and, perhaps not surprisingly, changes in the localization and activity of mechanistic target of rapamycin complex 1 (mTORC1) and AMP-activated protein kinase (AMPK), the two critical nutrient-responsive kinases that belong to a lysosome-based signaling system. We have found massive buildup of autophagic debris, a diminished mTORC1 activity, and excessive accumulation and activation of AMPK at the lysosome in the diseased muscle. Furthermore, we challenged the prevailing view in the field that the lysosomal glycogen storage does not lead to metabolic consequences in muscle cells. We

have shown that the metabolome profile of GAA-deficient muscle is reminiscent of that in cells with limited availability of glucose, and that there is a cross-talk between glycogen breakdown in the cytosol (phosphorylytic glycogenolysis) and hydrolysis of glycogen to glucose in the lysosome. Accumulation of the precursor of glycogen synthesis, a decrease in the metabolites of the glycolytic pathway, cellular energy deficit, and a shift to lipids as the energy source are observed in the diseased muscle. Pompe disease is one of several LSDs being treated with enzyme replacement therapy (ERT). The most consistent effect of ERT has been on cardiac pathology and function in infants who, unlike late-onset patients, invariably suffer from severe cardiomyopathy. Despite this considerable progress, the therapy is still not satisfactory since the effect in skeletal muscle is minimal. We have now tested a new experimental drug, AT-GAA (recombinant human GAA; Amicus Therapeutics), with much improved lysosome-targeting properties in a large pre-clinical study. Remarkably, this new drug reversed or significantly improved all aspects of the disease pathogenesis.

Multi-dimensional Mapping of Cell States during Cardiomyocyte Differentiation Using Live Imaging and RNA FISH.

M. Hendershott, S. M. Rafelski,.Allen Institute for Cell Science; Allen Institute for Cell Science, Seattle, WA.

The Allen Institute for Cell Science is developing a state space of stem cell structural signatures to study changes in cellular organization of human induced pluripotent stem cells (hiPSCs) as they differentiate into cardiomyocytes. We have used CRISPR/Cas9 to generate a collection of ~35 endogenous fluorescently tagged hiPSC lines (www.allencell.org), each expressing a monoallelic EGFP-tagged protein that localizes to a particular cellular structure or organelle. In addition, we have developed several pertinent methods: 1) scarless GFP-tagging of late expressing cardiomyocyte genes, including ACTN2, ssTNNI1, MYL2, MYL7 and TTN, to study the organization and morphogenesis of the contractile apparatus; 2) a robust protocol for differentiation of hiPSCs into cardiomyocytes and methods for preparing cells for imaging; and 3) image-based assays and segmentation algorithms that enable single-cell analyses of structure localization in differentiated cardiomyocytes. Using the cardiomyocyte-specific protein ACNT2 as a reference, we have also developed methods for quantifying the extent of sarcomeric organization in cells across timepoints, thus placing individual cells along a psuedotime axis based on their level of structural ACTN2 organization. We are also using this approach to analyze sarcomere maturation via other key sarcomeric structural and regulatory proteins. This permits us to use sarcomere organization state as a reference system to analyze the reorganization of cytoplasmic structures. We are now incorporating multiplexed fluorescence in situ hybridization (FISH) into this analysis, allowing us to directly investigate the connection between cell structure organization and gene expression profiles on a single-cell level and also to produce structure-referenced maps of RNA localization. This imaging pipeline is generating an image database of high-resolution, high-replicate image data of the fluorescently tagged structures with a goal of generating an integrated image “state space” of intracellular reorganization during cardiomyocyte differentiation.

P873/B894

Investigating the Contribution of Muscle Contractile Apparatus Genes to Muscle Function in *Caenorhabditis Elegans*.

L. Lesanpezeshki[1], K. Kashyap[1], J. Hewitt[1], R. Laranjeiro[2], M. Driscoll[2], N. Szewczyk[3], G. Benian[4], C. M. R. Lacerda[1], S. A. Vanapalli[1]; [1]Texas Tech University, Lubbock, TX, [2]The State University of New Jersey, Piscataway, NJ, [3]University of Nottingham, Derby, UNITED KINGDOM, [4]Emory University, Atlanta, GA.

Caenorhabditis elegans has been widely used as a model organism to study muscle function with their sarcomeres composed of dense bodies and M-lines, organizing and anchoring thin actin filaments and thick myosin filaments to the muscle cell membrane, respectively. Dense bodies and M-lines play substantial roles in muscle contractile apparatus by transmitting the force generated from muscle contraction to the basement membrane and cuticle permitting animals to engage in their undulatory locomotion. To elucidate the genes responsible for muscle performance, we have developed two novel assays that involve exertion of muscle forces by *C. elegans*. First, is a Pluronic gel-based burrowing assay (Lesanpezeshki *et al.,* 2019) that challenges the animals to move in 3D under a chemical stimulus. Second, is a microfluidic pillar-based platform called NemaFlex (Rahman *et al.,* 2018) that quantifies the maximum exertable force by animals. Using these assays, we scored mutants with defects in contractile apparatus from dense bodies and M-lines to thick and thin filaments, and interestingly, burrowing ability proved to be distinct from NemaFlex strength measurements. The key results thus far are: (i) *atn-1* (α-actinin), *uig-1* (Cdc42 GEF), *zyx-1* (zyxin), *tln-1* (talin) and *pfn-3* (profilin) mutants were not different from wild-type animals in NemaFlex scoring of muscle force, while *dyc-1* (capon), *dim-1, unc-95, unc-82* (serine/threonine kinase)*, unc-89* (obscurin)*, unc-54* (myosin heavy chain)*, lev-11* (tropomyosin) and *unc-60* (ADF/cofilin) genes played significant roles in muscle force exertion. (ii) All the tested mutants were impaired in burrowing compared to wild-type animals, highlighting the importance of the genes in muscle function. Interestingly, mutants in α-actinin, ADF/cofilin, and twitchin were among the most defective mutants for burrowing behavior of *C. elegans*. Thus, our assays can reveal phenotypic differences in animals with mutations affecting muscle function. We intend to investigate the structural defects of the sarcomere in these mutants using immunostaining techniques to understand if they can be related to the type of deficiencies detected in our burrowing and NemaFlex assays.

P874/B895

Using Developmental Biology to Identify Treatments for Disease: Crispr/cas9 Ablation of Individual MicroRNAs from a MicroRNA Family Reveals Their Individual Efficacies for Regulating Cardiac Differentiation.

G. I. Gallicano, 20057[1], A. Nawaz[1], S. Mahapatra[1], B. Brownson[2], C. Dillon, 20057[3]; [1]Georgetown University Med Ctr, Washington, DC, [2]Rye High School, Rye, NY, [3]Bishop O'Connell High school, Arlington, VA.

Developmental Biology can be used to identify treatments for disease. For example, genes involved in heart development have been identified as mis-expressed in heart failure (HF). We recently showed that many of these developmentally related HF genes are regulated by specific MicroRNAs. These small, non-coding RNAs use a 7-8 base-pair seed sequence to target a corresponding mRNA sequence resulting in rapid down-regulation of translation. MiRNAs can also control and promote protein homeostasis, which, if compromised, can result in developmental defects or initiation of disease. Here, we first identify that during differentiation, individual miRNAs that reside in the miRNA17 family do not share the same

function even though they have the same seed sequence. The advent of CRISPR/CAS9 technology has not only yielded a true observation of individual miRNA function, it has also reconnected advanced molecular biology approaches to classical cell biology approaches such as gene rescue. We show that miRNA106a and to a lesser extent miR17 and 93 target, in a dose-dependent manner, the cardiac suppressor gene (and HF gene) Fog2, which specifically suppress Gata-4 and Coup-TF2. However, when each miRNA is knocked out, we find that their targeting efficacies for Fog2 differ resulting in varying degrees of cardiac differentiation. Second, we apply and extend these developmental data to HF. Conditions such as coronary artery disease, high blood pressure, diabetes, etc., can cause cardiomyocytes to undergo hypertrophic changes that alter their structure and/or function ultimately resulting in HF. The current paradigm for treating HF is predominantly pharmacological intervention or surgery; however, with few exceptions, the condition usually worsens with time. Because the genes affected during development by miRNAs17, 20a, 93, 106a are also found mis-regulated during HF in adults, we have proposed a paradigm shift for treating HF from a drug-centric system to a molecular approach that would not simply treat symptoms but restore cardiac identity to affected cardiomyocytes. The approach utilizes the homeostatic duties of these four miRNAs to physically regulate genes that when mis-regulated demonstrably change the identity of cardiomyocytes.

P875/B896

Understanding the Role of the *Drosophila Melanogaster* Protein *Kismet*In Muscle Formation and Maintenance.

J. Barnell, T. Sadikot; Washburn University, Topeka, KS.

Drosophila melanogaster serves as a useful tool for studying disease-causing homologs in humans. The *Drosophila* gene *Kismet* is homologous to the *CHD7* gene found in humans. CHD7 plays a role in chromatin remodeling, and mutations in this gene are known to cause a dominant genetic condition called CHARGE syndrome. CHARGE syndrome is a complex disorder that is characterized by colobomas of the eye structures, atresia, fused or missing kidneys, various heart defects, impaired cognitive and physical development, hearing loss, and other ear abnormalities. Individuals diagnosed with CHARGE may also exhibit swallowing difficulties, esophageal reflux, delayed fine and gross motor skills, and delayed walking. While some of these issues are neurological, not much is known about the associated abnormalities in muscle structure, though low muscle tone in skeletal and smooth muscles is apparent. The goal of this project is to analyze muscle structure and integrity in different mutants of *Kismet* in *Drosophila melanogaster*. Expression of the various *Kismet* mutants will be carried out using the Gal4-UAS expression system in the fruit fly. Studying the role of *Kismet* in muscle development in *Drosophila* may help in understanding how mutations in *CHD7* cause low muscle tone and affect early muscle development in humans.

P876/B897

Disruption of Inhibitory System for Autoubiquitination by an R441q Missense Mutation in the *Wwp1* Gene in Chicken Muscular Dystrophy.

M. Imamura[1], Y. U. Inoue[2], T. Inoue[2], S. Arima[1], S. Takeda[1]; [1]Dept of Molecular Therapy, Natl Inst Neurosci/NCNP, Tokyo, JAPAN, [2]Dept of Biochemistry and Cellular Biology, Natl Inst Neurosci/NCNP, Tokyo, JAPAN.

The HECT-type E3 ubiquitin protein ligases play a crucial role to maintain the cellular homeostasis by controlling the gene expression and protein turnover by ubiquitination of target molecules. The *WWP1* gene encodes a 130-kDa HECT-type E3 ubiquitin ligase (922 amino acids) composed of three functional domain regions, i.e., an N-terminal C2 domain for calcium-dependent phospholipid binding, a central region containing four tandem WW domains recognize substrates with the proline-rich peptide motifs, and a C-terminal HECT catalytic domain for ubiquitin transfer from E2 to substrates. An R441Q missense mutation in the molecule causes muscular dystrophy in NH-413 chicken. The amino-acid substitution is located in the center of the cluster of four WW domains (between WW2 and WW3 domains), speculating that it would lead to abnormal activity of WWP1 by the alteration of specific interaction to substrates. However, our analysis of NH-413 chicken clearly showed that the marked degradation and loss of the sarcolemmal localization of WWP1 in the skeletal muscles. This result suggested that the missense mutation gives rise to the loss of function of WWP1 by its degradation. To test the hypothesis, we generated mice having the same missense mutation as that found in NH-413 chicken WWP1 gene and examined the stability of WWP1 proteins in the knock-in (KI) mouse. Biochemical, histological, and cellular analyses clearly showed the loss of WWP1 protein in skeletal muscles of the KI mice, which would be caused by autoubiquitination. Moreover, in the skeletal muscle of the mice lacking WW2, the second WW domain, the remarkable protein reduction was also observed as is the case with NH-413 chicken skeletal muscle. These findings are consistent with the recent structural study of WWP2 E3 that the peptide linker tethering WW2 and WW3 can lock HECT catalytic domain in an inactive conformation and a WW2 domain can also lock the enzymatic activity by blocking the ubiquitin-binding exosite of the molecule. The high conservation of primary structures between the WWP2 and WWP1 proteins leads to the possibility that the WW2-WW3 peptide linker would be also a key regulatory element of HECT catalytic activity in the WWP1 molecule and the linker-mediated autoinhibition could be relieved by R441Q missense mutation.

P877/B898

Protein Networks of Heart Regeneration.

M. I. Pronobis, S. Zheng, K. Poss; Duke University, Durham, NC.

The adult human heart is limited in its ability to regenerate after injury. Rather than producing new functional muscle tissue, the human heart forms scar tissue which often leads to heart arrhythmias and heart failures. Lower vertebrates like zebrafish have the ability to regenerate cardiac tissue after injury. Cardiomyocyte proliferation and activation of developmental programs have been shown to play key roles in zebrafish's ability to re-grow new tissue without scar formation. Transcriptional profiling and gene expression analyses in adult zebrafish have revealed profound changes in cardiomyocytes during heart regeneration. How these changes impact protein interacting networks in cardiomyocytes is unknown. Here we propose to capture and define the protein networks of different cellular compartments and regenerative factors in cardiomyocytes using BioID. This recently established

technique probes interacting networks of proteins by using a promiscuous Biotin ligase, BirA2, that attaches biotin to adjacent proteins. Biotinylated proteins are then isolated by streptavidin-based pull down and identified by mass spectrometry. Thus BioID allows capturing very transient protein interactions that might never be detected by standard methods. This study will define the functional networks of cardiomyocytes present during heart regeneration, and has the potential to reveal novel proteins that play key roles in cardiac repair after injury.

P878/B899

The Effects of AMPK Activators on Mitochondrial Turnover and Protein Synthesis in Developing Skeletal Muscle Cells in a High-Fat and High-Insulin Environment.

R. Masotti, C. Thomason, M. Purich, E. Kinsey, S. Kinsey; University of North Carolina Wilmington, Wilmington, NC.

AMP-activated protein kinase (AMPK) is a common target of diabetic therapies, and drugs that activate AMPK are increasingly applied to juveniles who are experiencing extensive muscle development. AMPK activation causes increased fatty acid oxidation, mitochondrial biogenesis, glucose uptake, and insulin sensitivity, but it also can limit protein turnover and muscle differentiation. Metformin, a member of the biguanide family, is an AMPK activator that, in muscle, targets the mitochondrial respiratory chain complex I. β-guanidinopropionic acid (β-GPA) is a creatine analog that mimics an energy stress within the cell, activating AMPK. The present study sought to assess the effects of high oleic acid (OA) and high insulin content on skeletal muscle cell differentiation, global protein synthesis, and mitochondrial turnover in the absence or presence of metformin and β-GPA. Cells treated with insulin produced significantly more myotubes per unit area over the 72-h treatment than all other treatment groups. Insulin treatment also elicited a significant increase in all markers of mitochondrial turnover (DRP1, SQSTM1, PGC1α, and OPA1) and global protein synthesis. The combined treatment of OA and insulin also elicited an increase in mitochondrial turnover markers, aside from OPA1, although the effect was smaller than for insulin alone, and there was no effect on global protein synthesis or myotube formation. In general, the addition of metformin or β-GPA reduced or eliminated the effect of insulin on mitochondrial turnover and protein synthesis. However, metformin groups that were cotreated with insulin or insulin + OA still displayed significant increases in markers of mitochondrial fission and mitophagy, but did not differ from controls in mitochondrial biogenesis, fusion, or global protein synthesis. Further, metformin + insulin resulted in high rates of myotube formation. These results are consistent with established effects of AMPK on protein synthesis, and growing evidence that mitochondrial turnover is compromised by AMPK-activating compounds.

P879/B900

Human Mesenchymal Stem Cells Primed with *Estradiol* Enhance*Angiogenesis* in Heart Tissue.

M. Mihai; Regenerative Medicine, ICBP "Nicolae Simionescu", Bucharest, ROMANIA.

Background/Aims: When detected early, heart disease, can be managed by life style changes or medical or surgical approaches. However, in advanced disease, heart transplantation remains the only viable option. Unfortunately, this option is constrained by the scarcity of gender-matched donors, and, also, highlights the importance of mesenchymal stem cells (MSCs) as a therapeutic tool for heart repair. However, inefficient incorporation, retention, and activity of MSCs in cardiac tissue remains an obstacle. Since surge in follicular estradiol (E2; μmolar-range) triggers tissue remodeling (e.g. ovulation) and E2

exerts beneficial actions on the cardiovascular system, we hypothesized that E2 may promote/improve MSC-mediated cardiac repair processes. **Methods:** Wharton's jelly (WJ)-derived MSCs were used, to assess the effects of E2 on their proliferation, directed-migration and engraftment in murine heart slices, *ex vivo* (measured using xCELLigence real-time cell-impedance system, DNA-quantification, and microscopy). Protein expression was assessed by Western blotting, ELISA/Luminex and proteomic analysis, whereas mRNA expression by qRT-PCR. **Results:** MSCs expressed estrogen receptors (ERs) -alpha and -beta. E2 promoted MSCs proliferation and up-regulated mRNA and protein expression of ER-alpha, ER-beta, extracellular matrix metalloproteinase inducer (EMMPRIN), and matrix metalloproteinase (MMP) -9, yet down-regulated MMP-2 expression. Moreover E2, up-regulated expression of vascular endothelial growth factor (VEGF)-A, vascular cell adhesion protein-1 (VCAM-1) and an giogenin (ANG), and stimulated nitric oxide (NO) production via ER. Proteomic analysis revealed that in MSCs, E2 up-regulated 47 proteins, down-regulated 7 proteins, and increased the expression of key biochemical components/pathways involved in tissue repair. In MSCs co-cultured with murine cardiac-slices, E2 significantly induced MSCs migration in an ER-dependent fashion (and preferentially via ER-alpha) and significantly increased the secretion of MMP-2, MMP-9, ANG and VEGF. In an in *vivo* matrigel assay, E2-treated MSCs increased angiogenesis and hemoglobin content. **Conclusion:** E2 facilitates the integration/engraftment of MSCs into heart slices by promoting MSC proliferation, migration and angiogenesis. These beneficial effects are mediated via increases in molecules/pathways involved in tissue remodeling and angiogenesis. We speculate that priming of MSCs with E2 may enhance their ability to repair/regenerate cardiac tissue in women.

P880/B901

Resolved Structural States of Calmodulin in Regulation of Skeletal Muscle Calcium Release.

M. R. McCarthy, Y. Savich, R. L. Cornea, D. D. Thomas; University of Minnesota, Minneapolis, MN.

Calmodulin (CaM) is proposed to modulate skeletal muscle sarcoplasmic reticulum (SR) calcium release channel (ryanodine receptor, RyR1 isoform) activity in a conformation-dependent manner. However, the correlation between CaM structure and functional regulation of RyR in physiologically relevant conditions is largely unknown. We have used time-resolved fluorescence resonance energy transfer (TR-FRET) to study structural changes in CaM that may have a role in the regulation of RyR1. We covalently labeled each lobe of CaM (N and C) with fluorescent probes, and used intramolecular TR-FRET to assess interlobe distances when CaM is bound to RyR1 in SR membranes, purified RyR1, and a peptide corresponding to the CaM-binding domain of RyR (RyRp). TR-FRET resolved the equilibrium between two distinct structural states (conformations) of CaM, each characterized by an interlobe distance and width (disorder). In isolated CaM, at low Ca^{2+}, the two conformations of CaM are clearly resolved, centered at 5 nm (closed) and 7 nm (open). At high Ca^{2+}, disorder increases and the equilibrium shifts to favor the open conformation. In the presence of RyRp the resolution (order) of the two CaM conformations increases, with the closed conformation more compact and the major component. With CaM bound to full-length RyR1, either purified or in SR membranes, strikingly different results were obtained: (1) the two conformations are more clearly resolved and ordered, with the closed state more ordered than the open state. (2) the open state is the major component. (3) Ca^{2+} stabilized the closed conformation by a factor of two. We conclude that the Ca^{2+}-dependent structural distribution of CaM bound to RyR1 is distinct from that of CaM bound to RyRp. We propose that the function of RyR1 is tuned to the Ca^{2+}-dependent structural dynamics of bound CaM. These data suggest that the structure

of CaM when bound to the peptide is not representative of CaM binding to full-length RyR1. This striking result has implications for many other CaM binding partners that have been structurally characterized through peptide studies. Ongoing studies utilize purified RyR1 to directly measure CaM-RyR binding kinetics, the structural changes that contribute to regulation of the cardiac RyR isoform (RyR2), and how oxidation and disease-causing mutations in CaM affect the CaM-RyR interaction. This work was supported by NIH grants AG26160 (DDT), HL092097 (RLC) and 1F31AG052329-01A1 (MRM) and an American Heart Association Predoctoral Fellowship 15PRE25700131 (MRM).

P881/B902

***Dystrophin and Ensconsin* Have Opposing Roles in Regulating Nuclear Positioning.**

A. A. Burgess, E. Wynn, S. Sawicki, E. S. Folker; Boston College, Boston, MA.

Long-range movements of nuclei during skeletal muscle development is evolutionarily conserved suggesting that these movements are critical for proper muscle development. Consistent with this, one characteristic of poorly functioning muscle is disruption in the spacing of nuclei. Muscle cell structure is highly conserved between *Drosophila melanogaster and* mammalian muscle, making it an ideal model organism to understand the mechanisms that drive and the functions of nuclear positioning. We have shown that mutations in several genes associated with muscular dystrophies cause nuclear positioning defects in *Drosophila* that resemble their effects in patients. Specifically, *Dystrophin*, a Duchenne muscular dystrophy-linked gene, and *ensconsin*, a cofactor of the microtubule motor protein kinesin, are necessary for proper nuclear positioning. Both have been shown to bind microtubules in mammals, which could indicate they may regulate nuclear positioning via similar mechanisms. To determine if two genes are using the same pathway to coordinate position of nuclei, we conducted genetic interaction studies. An imals heterozygous for mutations in either gene individually displayed a minor disruption in the spacing of nuclei. Surprisingly, in animals that were heterozygous for a mutation in each gene, nuclear positioning was similar to that in wild type animals. These data suggest that *Dystrophin* and *ensconsin* work within the same genetic network, but that within this network they have opposing functions that must be properly balanced to efficiently position nuclei.

Scholarship of Diversity

Diversifying the STEM Doctoral Population: Time to Look Beyond the GRE and Revise Graduate Admissions Policies Diversifying the Stem Doctoral Population: Time to Look Beyond the Gre and Revise Graduate Admissions Policies.

J. Vigoreaux[1], K. Gile[2], E. Erenrich[3], D. Levine[4], S. Petersen[2]; [1]University of Vermont, Burlington, VT, [2]University of Massachusetts at Amherst, Amherst, MA, [3]Rutgers, the State University of New Jersey, New Brunswick, NJ, [4]University of New Hampshire, Durham, NH.

The selection of students for science, technology, engineering and mathematics (STEM) doctoral programs determines who will be leaders in research, higher education, and fields that underpin the U.S. economy. For decades, this selection process in most U.S. universities has relied heavily on the Graduate Record Examination (GRE), a test originally developed to "level the playing field" for applicants from variously ranked educational institutions. The merit of the GRE as a selection tool for graduate admissions has been long debated as well as its potential to disproportionally compromise admission of women and students historically underrepresented in STEM who score less well on the GRE than other groups. In the present study, we sought to determine whether GRE scores are predictive of PhD completion in a broader range of STEM fields and whether there are gender differences in the predictive abilities of the GRE. To obtain sufficient data for meaningful comparisons, we collected information on over 1800 students from four variously sized state flagship research universities that participate in the Northeast Alliance for Graduate Education and the Professoriate (NEAGEP). The Alliance is a long-standing collaboration originally funded by the National Science Foundation to diversify STEM PhD programs. We found that GRE Verbal (GRE V) and GRE Quantitative (GRE Q) scores were similar for women who completed STEM PhD degrees and those who left programs. Remarkably, GRE scores were significantly higher for men who left than counterparts who completed STEM PhD degrees. In fact, men in the lower quartiles of GRE V or Q scores finished degrees more often than those in the highest quartile. This pattern held for each of the four institutions in the study and for the cohort of male engineering students across institutions. GRE scores also failed to predict time to degree or to identify students who would leave during the first year of their programs. These findings show that GRE scores do not predict what are arguably the most important indices of preparedness for STEM PhD studies—persistence beyond the first year, time to degree or STEM PhD completion. In conclusion, we suggest it will be important to: (i) identify characteristics that motivated admissions committees to ignore the low GRE scores; (ii) determine whether these characteristics contributed to the success of the low-scoring men; (iii) develop more effective and inclusive graduate admissions strategies.

P883/B2

How Hhmi Is Encouraging Science Workforce Diversity through Institutional Change.

M. Juarez; Howard Hughes Medical Institute, Chevy Chase, MD.

Science education programs, including those funded by the Howard Hughes Medical Institute (HHMI), have historically promoted scientific workforce diversity mainly via student-centered interventions. While these programs can directly help student participants, they have generally not led to significant and lasting change required to close the gaps between those who become scientists and those that are excluded from science. We believe that much of the responsibility for advancing diversity does not rest

on students but on institutions in which students find themselves. Therefore, the HHMI Science Education Undergraduate and Graduate Programs (UGP, https://www.hhmi.org/science-education/programs) has shifted away from funding programs that solely focus on "fixing the students" to those that address institutional barriers for participation of persons who belong to groups historically excluded from science. We pursue a systems approach aimed at establishing a more inclusive scientific environment. Our hypothesis is that, by focusing on learning environment and institutional culture, improvement in diversity and inclusion will be substantial and sustained. This approach informs all UGP programs, including: the Inclusive Excellence initiative, which seeks to increase the capacity for inclusion on each grantee campus through faculty development, curriculum revision, and changes in policies and practices; the Gilliam Graduate Fellowships Program, which engages the dissertation advisers of the Gilliam Fellows in a year-long series of activities that provide culturally-responsive mentor training; the HHMI Professors initiative, which empowers accomplished scientist faculty to explore critical issues in education and transform the climate for education at research universities; and the HHMI Science Education Alliance, whose PHAGES course is an inclusive course-based research and educational community (iREC), enabling beginning undergraduates from all backgrounds and all institution types to engage in authentic research. We recognize our responsibility to learn from the grantees and to continually refine frameworks that can inform future efforts. Applying theory of change practices, we are actively examining our assumptions about these initiatives and strive to foster a dynamic stance to promote our aspirational goal: inclusion is foundational to excellence in science.

P884/B3

Scientific Societies Join Forces to Amplify Effectiveness of Stem Workforce Diversification Programming.

V. A. Segarra[1], M. Ramirez-Alvarado[2], A. Edwards[3], C. Fry[4], J. Kwak[5], M. Lawson[6], R. McGee[7], D. Neely-Fisher[8], S. Ingram Osborn[9], D. Snowflack[10], K. Suggs[11], S. Valtierra[7], L. Vega[12], E. Vuong[5]; [1]High Point University, High Point, NC, [2]Mayo Clinic, Rochester, MN, [3]American Society for Cell Biology, Bethesda, MD, [4]American Society for Pharmacology and Experimental Therapeutics, Bethesda, MD, [5]Biophysical Society, Rockville, MD, [6]University of California San Diego, San Diego, CA, [7]Northwestern University, Chicago, IL, [8]Reynolds Community College, Richmond, VA, [9]Oregon Health & Science University, Portland, OR, [10]American Society for Biochemistry and Molecular Biology, Rockville, MD, [11]The Endocrine Society, Washington, DC, [12]Barry University, Miami Shores, FL.

Despite increasing awareness of the benefits that come with having a diverse STEM workforce, efforts to increase the number of URM scientists have met with limited success. In professional scientific societies, diversity-focused committees continue to play essential roles in the efforts of scientific societies to foster inclusion and facilitate the professional development of underrepresented minorities (URMs) in their respective scientific disciplines. Until recently, the efforts of these committees remained independent and disconnected from one another. Funding from the National Science Foundation has allowed several of these committees to come together and form the **A**lliance to **C**atalyze **C**hange for **E**quity in **S**TEM **S**uccess, herein referred to as ACCESS. The overall goal of this meta-organization is to serve as a community in which diversity-focused committees can interact, synergize, and have a unified voice, enabling them to better address the needs and concerns of URMs in STEM disciplines based on their collective experiences. To accomplish this, ACCESS meets regularly to share data and best practices in programmatic assessment and structures. As an example of our work, we compare and contrast the broad range of ways in which scientific societies implement and assess their travel award programs for

URMs. We also report a set of recommendations, including both short- and long-term assessment of outcomes in populations of interest and specialized programmatic activities coupled to travel award programs. ACCESS plans to launch a website in 2020 to broadly disseminate ways in which societies are implementing STEM workforce diversification programs, such as travel awards. Our ultimate goal is to broaden ACCESS to encompass additional societies, including those wanting to develop programs for diversity and inclusion and those with existing programs.

P885/B4

Mental Health and Wellness in Stem: Facilitating an Open and Necessary Discussion About Our Community and Our Identity.

E. L. Sanchez, M. Spear, B. Pizer, D. Duncan; University of California, San Francisco, CA.

Graduate student and postdoctoral mental health and wellbeing has only recently emerged as a topic of serious discussion within the STEM community. Surveys of STEM trainees have revealed that a significant number of members of our research community face mental health and wellness challenges at some point throughout their training careers. Furthermore, seeking help for mental wellness can be a major challenge during STEM training, and an even larger challenge for underrepresented scholars. Our goal was to develop and facilitate a workshop that not only discussed the current evidence that mental health and wellness challenges are common in our STEM research community, but we also wanted to invite trainees to join a “brave space” in which to consider resources and strategies to acknowledge and seek support for their mental health. To this end, we designed a workshop that focused on how our community of STEM researchers contribute to mental health and wellbeing. Using a case study approach, we ask participants to consider not just the trainee facing mental health challenges, but also to consider the perspective of cohort/lab mates, and even the perspective of the advisors/mentors. We want to make the point that if our career plans are to remain in academia, we may participate as the trainee, the labmate, and the mentor at some point in regards to the mental health of trainees in the community. We argue that understanding how each member of the STEM training community can impact a mentee’s experience is crucial. Moreover, we discussed how our personal identities impact our experiences with mental health, and how the identities of those in our community may impact how we interact with them or share with them during times of mental health struggles. In the last year we have presented this workshop at the SACNAS National Conference, at the ABRCMS National Conference, at UC San Francisco, and at UC Berkeley. We continue to revise and improve the workshop with each presentation and look forward to facilitating these important conversations about mental health and wellness with STEM trainees, faculty, and administrative staff.

P886/B5

The Impact of a Short Summer Bridge Program on Success and Retention of First Generation Biology Majors at a Residential Liberal Arts College.

A. Packer, T. Peeler, **M. Peeler**; Susquehanna University, Selinsgrove, PA.

To address the shortage of skilled STEM professionals in the US, as well as the need for increased representation in the STEM workforce, many colleges and universities have developed summer bridge programs designed to improve the persistence of first-generation, low income, and/or underrepresented students in STEM majors. At Susquehanna University, a small (2,300 total students with about 300 life science majors) undergraduate institution in rural Pennsylvania, we have conducted

summer bridge programs for the past 8 years, initially supported by NSF funding and more recently by the university. Each year, we invite approximately 10 students to attend. Invitations are extended primarily to first-generation students with high financial need. This targeted population typically includes significant racial diversity. These students spend a week on campus the summer before matriculating, learning about research opportunities, working with science faculty, and gaining an introduction to campus resources. Equally important, it allows them an opportunity to develop a social network of peers prior to arriving on campus in the fall. The program is free of charge to the students and operates at a modest cost to the institution (approximately $10,000 per summer). We have previously shown that students who participated in the first 4 summer bridge programs graduated with science degrees at a significantly higher rate than a matched control group. In this study, we analyze more specifically the impact of the summer bridge program on a variety of success markers as well as a self-reported sense of belonging as a science major. We found that sex and race significantly affected students' level of agreement with the statement "I can do well in the sciences at Susquehanna". While participation in a pre-orientation program did not significantly affect students' level of agreement with the statement, there was a significant interaction between race and participation in a pre-orientation program. We found white students had higher first semester GPAs (3.24+/-0.10 v. 2.83 +/-0.14) and second semester GPAs (3.29+/-0.13 v. 2.75+/-0.17) than students of color. However, when we included the number of high school science classes as a covariate in the model, we found that race no longer has a significant effect on first semester GPA. White students reported taking significantly more science classes in high school. In summary, there are multiple ways in which student identity, background, and participation in a short summer bridge program impacts student success and sense of belongingness for under-represented biology students.

P887/B6

Insights from a Survey-based an alysis of the Academic Job Market.

S. Sarabipour[1], J. D. Fernandes[2], C. T. Smith[3], N. M. Niemi[4], N. M. Jadavji[5], A. J. Kozik[6], A. S. Holehouse[7], V. Pejaver[8], O. Symmons[9], A. W. Bisson Filho[10], **A. Haage**[11]; [1]Johns Hopkins University, Baltimore, MD, [2]University of California, Santa Cruz, CA, [3]North Carolina State University, Raleigh, NC, [4]University of Wisconsin-Madison, Madison, WI, [5]Midwestern University, Glendale, AZ, [6]University of Michigan, an n Arbor, MI, [7]Washington University School of Medicine, St. Louis, MO, [8]University of Washington, Seattle, WA, [9]University of Pennsylvania, Philadelphia, PA, [10]Brandeis University, Waltham, MA, [11]University of North Dakota, Grand Forks, ND.

Many postdoctoral fellows in the STEM fields enter the academic job market with little knowledge of the process and expectations, and without any means to assess their qualifications relative to the general applicant pool. Demystifying this process is critical, as there is little information publicly available. In this work, we provide insight into the process of academic job searches by gathering data to establish background metrics for typical faculty job applicants, and further correlate these metrics with job search outcomes. We analyzed 317 responses to an anonymous survey for faculty job applicants from the May 2018 - May 2019 market cycle. Responses were about evenly split by gender, largely North American-centric and life science focused, and highly successful with 58% of applicants receiving at least one offer. Traditional metrics (funding, publications, etc.) of a positive research track record above a certain threshold of qualifications were unable to completely differentiate applicants that did and did not receive a job offer. Our findings suggest that there is no single clear path to a faculty job offer and that perhaps criteria not captured by our survey may also influence landing a faculty position above a certain

threshold of qualification. Furthermore, our survey did capture applicants' perception of the faculty job application process as unnecessarily stressful, time-consuming, and largely lacking in feedback, irrespective of a successful outcome. We hope that this study will provide an avenue for better data-driven decision making by the applicants and search committees, better evidence-based mentorship practices by principal investigators, and improved hiring practices by institutions.

P888/B7

The ASCB MAC Faculty Research and Educational Development (FRED) Program Has Resulted in Program Participants/Mentees Who Successfully Compete for Grant Support.

L. Hammonds-Odie[1], R. Aguilera[2], M. J. Leibowitz[3], J. Quill[4], A. Edwards[5], F. Chacon[5], P. Hughes[1]; [1]Department of Biology, School of Science and Technology, Georgia Gwinnett College, Lawrenceville, GA, [2]Department of Biological Sciences, University of Texas at El Paso, El Paso, TX, [3]Department of Medical Microbiology and Immunology, School of Medicine, University of California-Davis, Davis, CA, [4]C. J. Quill & Associates, Inc, an napolis, MD, [5]American Society for Cell Biology, Bethesda, MD.

Access to national funding is generally required for career advancement and promotion/tenure and was identified as a barrier for junior faculty members in a recent study. The Minorities Affairs Committee (MAC) of the ASCB has a long history of providing career development opportunities for minority cell biologists. In 2013, a team of MAC members applied to the NSF for support for the Faculty Research and Education Development (FRED) Program, an intervention to promote grant funding success of minority senior postdoctoral fellows and junior faculty members and junior faculty members at MSIs. The year-long FRED Program activities kick off with a three-day summer workshop in which the mentees learn about NIH and NSF funding opportunities and hear from near peers and MAC members about the tenure process and collaboration establishment. A major component of the workshop is the one-on-one mentee-mentor meeting time to work on the specific aims or summary section of the proposal. Each of the mentees is required to submit a proposal for the mock review panel/study section held during the ASCB annual meeting in December. The mentees and mentors serve as reviewers during this mock session. Also, each pair of mentee and mentor engage in reciprocal visits to each other's institutions. This is critical for the mentors from research-intensive institutions to appreciate the research environment of the faculty at MSIs and more teaching-intensive institutions. The FRED Program has had 5 cohorts of mentee and mentor pairs. The 6th cohort will finish the Program in June 2020. The mentees have been a diverse group of individuals - 42% are Hispanic, and 20% are African-American. Over 60% are women. These mentees reported promotions, publications, collaborations, and other significant events that came about in part because of their involvement in the Program. While the national funding rates at the NSF and NIH are below 10%, 19 (53%) of the FRED mentees have been successful in attaining funding with 28 total proposals funded. Thus, the FRED Program model has been an effective approach for junior faculty to compete successfully for grants from NIH, NSF, and other federal agencies, as well as from private-sector funding entities. This work was supported by NSF Award 1340395.

Science Education: Innovations in Teaching and Learning

P889/B9

Share Your Expertise and Enthusiasm with Teachers: Organize a Workshop to Build Inexpensive Microscopes for Classrooms.

B. Goldstein; University of North Carolina, Chapel Hill, NC.

To get low cost microscopes in front of kids and teachers, I've been running microscope-building workshops for elementary school teachers. I use Kenji Yoshino's design, which he described in an Instructable entitled "$10 Smartphone to digital microscope conversion!" This is a simple and clever design for a low cost, DIY microscope that takes advantage of ubiquitous smartphone cameras. The microscopes are mostly transparent, making their inner workings obvious to teachers and kids. An d all of the parts are readily available from hardware stores or online, so teachers or kids can make more anytime if they wish. Based on feedback from teachers, I enlarged Kenji's design to accommodate iPads and other tablets, which are available in many elementary schools, and I've made other minor improvements. Teachers have reported back that groups of kids interact with each other around each microscope, looking at the smartphone or tablet screen together — a big improvement over microscopes in which kids might see only their own eyelashes, and in which only each kid would know what they saw. For the workshops, I prepare enough materials for each teacher to build their own microscope to keep in their classroom. A workshop with about a dozen teachers can equip a school with a complete set to move from classroom to classroom. Most of the workshop last 90 minutes, during which three things happen: (1) the teachers assemble the microscopes, (2) they develop expertise using the microscopes as they take pictures of things they brought with them, and they collect images to share (see image galleries at www.diymicroscopes.org), and (3) teachers brainstorm about how they'll use the microscopes to best match their curriculum needs and kids' interests. My current work includes bringing workshops to high poverty school districts in North Carolina and to statewide teachers conferences, and setting up to assess outcomes. At this poster there will be some of the microscopes for anyone to try, and I'll share a protocol that you can use to get started running your own workshops with teachers at local schools. An d I'll be happy to talk with people about collaborating or helping you get started running similar workshops on your own.

P890/B10

Building a Successful High School Outreach Project with Undergraduate Mentors: the Prince Edward County Environmental Molecular Biology Institute (PECEMBI).

M. J. Wolyniak[1], A. R. Barber[2]; [1]Hampden-Sydney College, Hampden-Sydney, VA, [2]Longwood University, Farmville, VA.

With financial support from an ASCB Public Engagement Grant funded by the Science Sandbox, an initiative of the Simons Foundation, we launched the Prince Edward County Environmental Molecular Biology Institute (PECEMBI), an outreach program connecting the students of Hampden-Sydney College and Longwood University with the students of Prince Edward County High School, Virginia. Prince Edward County is a rural, underserved school system in central Virginia with a significant population of students from groups traditionally underrepresented in the STEM disciplines. In the fall semester, undergraduates from Hampden-Sydney and Longwood visited the high school each week and worked with biology students on a long-term project that explored the microbiome of student-selected locales around the school and introduced students to microbiology and molecular biology techniques. The spring semester featured work on examining the microbial contents and the quality of the watershed around the high school to consider issues more directly related to environmental biology. Both semester's activities culminated with a public presentation in coordination with Longwood's student research symposia. While Hampden-Sydney and Longwood faculty were present at each session, the undergraduates led all activities and discussions with the high school students as much as possible.

Assessment of the program conducted via surveys administered to high school students and teachers as well as Hampden-Sydney and Longwood undergraduates and faculty revealed high levels of enthusiasm and satisfaction among all participating parties in the program. While the high school students especially enjoyed the opportunity to participate in an authentic research experience and to interact with the undergraduate students, they expressed their hope that in future iterations of the program that the specific undergraduates working with them would not change from week to week. Likewise, both the high school and undergraduate faculty expressed praise for the overall work of the undergraduates but saw value to place more training emphasis in future iterations on the cultural aspects of successfully mentoring high school students. Overall, PECEMBI gives high school students insight into how college level research is done, how to summarize and present their research at a university poster session, and how to respond to peer criticism. It is PECEMBI's goal to supplement the scientific educations of the high school students in Hampden-Sydney's and Longwood's backyard and better prepare them for potential careers in science.

P891/B11

Six New York City (nyc) Medical Schools Will Offer Two Summer-long, Eight Weeks/summer, Professional Development (pd) Programs for New York City'S Secondary Science Teachers Beginning in Summer 2021.

S. C. Silverstein[1], J. Wiederhorn[2]; [1]Columbia University Coll Phys & Surg, New York City, NY, [2]Associated Medical Schools of New York, New York City, NY.

The U.S.'s current biomedical research workforce does not mirror the demographics of its population, seriously limiting our nation's scientific enterprise. Research shows that workforce diversity has beneficial outcomes including increased productivity, higher quality, and higher impact work (Valantine, H.A. An d Collins, F. S. *PNAS U.S.A.*112, 12240-12242, 2015). However, to increase diversity of the biomedical workforce, we must increase the number of underrepresented (UR) students entering STEM fields. UR students show strong interest in STEM fields upon matriculation into college, but 50-70% of them drop out before graduation (Meyers L.C., *PLoS ONE*13(1), 2018). Of all U.S. bachelor degree recipients, only ~21,000 Black and ~26,000 Hispanic students received STEM degrees, compared to ~195,000 White and ~39,000 Asian students (https://nces.ed.gov/pubs2016/2016007.pdf). This deficit in STEM education of UR students is due, in part, to inadequacies of secondary science teacher preparation in teaching inquiry-based science. The educational skills of most science teachers plateau 3-5 years after their entry into teaching. Columbia University's Summer Research Program (CUSRP) for Secondary Science Teachers was designed to address these deficits. Outcomes studies show that following teacher completion of Columbia's two summer-long, eight week/summer program, 10% more students of participating teachers pass New York State Regents science exams than students in classes taught by non-participating teachers in the same school at the same time. Participating teachers are retained in education at an ~3.5-fold higher rate than non-participating teachers. As such, New York City's (NYC) Department of Education saves educational costs for courses and exams students do not have to repeat and teachers it does not have to replace (*Science*326, 440-442, 2009). The program, its graduates, and their students have been recognized by 75 national, state and local educational awards since 2003 and has been replicated successfully at multiple sites, both in and outside of New York State. The program's success has prompted AMSNY, whose mission is to increase diversity of the biomedical and physician workforce, to engage a consortium of six of its member medical schools, to jointly implement CUSRP-like secondary science teacher professional development (PD) programs in NYC. These PD programs will

result in the further professional growth of experienced teachers, higher science teacher retention rates, elevation in the quality of STEM education in NYC's schools and a significant increase in the number of UR students prepared for post-secondary STEM education and careers.

P892/B12

Benefits of Collaborative Learning in Undergraduate Neuroscience Education.

T. Newpher; Duke University, Durham, NC.

Collaborative learning is an evidence-based instructional strategy that facilitates rich discussions between students to deepen student engagement and learning. This pedagogical approach increases learning gains and reduces failure rates among undergraduate students in STEM courses. In addition, student participation, motivation, and self-efficacy can all be increased with these structured learning environments. One such structured, active learning environment is Team-Based Learning (TBL). In TBL, students spend the majority of classroom time applying course content, analyzing data, synthesizing new ideas, and evaluating hypotheses. Importantly, previous studies have shown that learning outcomes and student course satisfaction are higher in courses that use TBL, compared to lecture-based classrooms. To better understand how TBL improves student learning and course satisfaction, I collected end of semester course evaluations and measured student-perceived classroom dynamics, as well as learning of lower and higher order levels of Bloom's taxonomy. My results suggest that implementation of TBL in an undergraduate neuroscience classroom improves student-perceived learning in both lower order (gaining knowledge, understanding concepts) and higher order (learning to apply and synthesize) levels of Bloom's taxonomy. These increases are consistent with the strong emphasis placed on application and synthesis within a TBL classroom.

P893/B13

Using Yeast Two-hybrid in Introductory Biology to Reinforce Molecular Biology Skills and Concepts.

P. Collado Cordon[1], M. Grider[2], S. Walsh[3]; [1]Rollins College, Winter Park, FL, [2]The Outer Banks Center for Dolphin Research, Kill Devil Hills, NC, [3]Soka University of America, Aliso Viejo, CA.

Course-based undergraduate research experiences (CUREs) expose a broad audience to authentic research questions and permit a professor to continue their own studies in the context of a high teaching load. As part of a second semester introductory biology course that emphasized genetics, students conducted an eight-week yeast two-hybrid screen to identify novel interactors of a zebrafish mitochondrial protein using a zebrafish cDNA library. In the context of yeast two-hybrid, students learned a variety of basic laboratory skills including DNA isolation from both yeast and bacteria; restriction digests, plasmid mapping, and agarose gel electrophoresis; bacterial transformation and yeast mating; and in *silico* methods analyzing raw DNA sequences and mining a genome database. Throughout this process, lecture concepts regarding gene structure, transcription, and translation were reinforced. Students identified many potential interactors, which they then researched through primary literature and protein databases to evaluate as bonafide candidates or false positives based on subcellular localization and known cellular function. After these informed predictions were made, the students then did pairwise validation matings to refute or affirm their hypotheses. Finally, they described their project and proposed alternative methods to identify protein-protein interactions in a cumulative research paper. Importantly, this large-scale screen served not only as a classroom tool, but also provided a new trajectory for later independent projects in the research laboratory.

P894/B14

Using Iteration and Relevancy to Scale Authentic Research Experiences for All Introductory Biology Students.

A. Campbell, D. M. Thurtle-Schmidt, S. N. Rosemond, R. El Bejjani, S. Sarafova; Davidson College, Davidson, NC.

The seminal educational report *Vision and Change*called upon scientists and educators to provide all their students with authentic research experiences in teaching laboratories. Course-based undergraduate research experiences (CUREs) scale research experiences for many students in a teaching laboratory setting. However, implementing CUREs in introductory classes is challenging and often requires students to opt-in to the experience through specialized first-year programs. Here we describe a simple CURE innovation that uses iteration and sustains relevance throughout the semester to provide students with a genuine research experience in their introductory cell and molecular laboratory course. As measured by the Laboratory Course Assessment Survey (LCAS; n = 63), students perceived this iterative lab course similar to how students perceived their specialized CURE courses. Over the semester, students exhibited marked gains in scientific self-efficacy. Additionally, students reported cognitive project ownership similar to students in research laboratory courses. Thus, students in this minimally redesigned introductory laboratory reported many of the gains often restricted to upper-level or specialized research-based laboratory courses. We offer a low-cost model for introductory laboratory courses that easily scales within traditional time allocations as a powerful intervention at no additional costs to institutions.

P895/B15

Fibroblast Spheroids and Other Models of Wound Healing and Infectivity.

V. Virador[1], N. Hassan Tehrani[2], S. Adkins[1], A. Devlin[1], G. Virador[3]; [1]MONTGOMERY COLLEGE, Rockville, MD, [2]University of Maryland, Rockville, MD, [3]Universidad de Navarra, Pamplona, SPAIN.

The goal of our research is to create a functional in *vitro* 3D model of skin for the purpose of experimentation. This project is being carried out in Montgomery College as part of a semester-long Introduction to Scientific Research class, taught to second year students. Students start using NIH 3T3 fibroblasts in two dimensional monolayers (2D), then transition to the use of spheroids, in-vitro three-dimensional models (3D) while conducting novel independent mentored research. We optimized parameters of spheroid growth, such as time, size and the number of cells in culture. In parallel, we optimized the MTT assay to see if it correlated with spheroid growth and our results agreed with published studies. We obtained reproducible decreases in spheroid viability using hydrogen peroxide to induce cellular damage and we obtained similar decreases when we used *Staphylococcus aureus* lipoteichoic acid (LTA) to induce a stress response associated with infection. An other substance tested was Manuka Honey, which has been shown to be effective in wound healing without scarring and possesses antimicrobial activity. In this case, we observed a reproducible increase in cell viability which suggested improved spheroid health. We have modified wound healing assays by using a combination of monolayer and 3D systems. Our results suggest that these hybrid spheroid models may be useful to identify natural compounds with relevance to wound healing.

Building Better Beer through CUREs: Undergraduate Classroom/brewery Collaborative Molecular and Cellular Biology Research.

M. J. Wolyniak[1], D. L. Beach[2]; [1]Hampden-Sydney College, Hampden-Sydney, VA, [2]Longwood University, Farmville, VA.

It is established that undergraduates benefit greatly from the introduction of authentic research experiences into life science coursework; however, such experiences can be difficult to engineer in a meaningful way, especially at smaller institutions where instructors must balance high levels of teaching with scholarly activity. An other issue arises with an enthusiasm gap observed by many students when the research opportunities presented in classes do not have medical or clinical relevance. To address both of these issues and to generate an exciting authentic research experience for our molecular and cellular biology classes, we teamed up with Third Street Brewing, a microbrewery based in Farmville, Virginia, to develop a semester-long course-based undergraduate research experience (CURE). In this CURE, students were tasked with "improving" budding yeast (*Saccharomyces cerevisiae*) strains according to the specifications of the brewery. For the pilot run of the project, the brewery specifically requested modifications that would alter flocculation tendencies of the yeast cells or the production of specific chemical byproducts during fermentation. Students were tasked with bioinformatics analyses to find target genes to manipulate in support of the brewer's goals and to develop research proposals. Over the course of the semester, students did gene deletions, site-directed mutageneses, gene induction experiments, and other molecular biology manipulations that could be tested for the brewer's specifications. While the semester did not provide enough time for most groups to bring an altered strain to completion, the experimental progress laid the groundwork for future students to complete the strains in either independent research or CURE settings. Assessment of the CURE through post-course surveys of students revealed that the project was successful in generating enthusiasm for learning molecular biology techniques and cell biology processes through CURE-based work on a project with obvious practical applications. The assessments also revealed a discomfort with the level of freedom provided throughout the project and the lack of specific instructions for completion of the project, suggesting that future iterations of the CURE may benefit from the addition of guidelines that provide more structure to the project while preserving the independent spirit of the CURE. Overall, this CURE showed the utility of working with businesses and organizations in the local community to develop research opportunities for undergraduates that can generate enthusiasm through the potential for discernable practical benefits. The use of budding yeast in the context of brewing also provided a CURE model that is accessible to institutions of all types and infrastructure levels.
